Iron; Use of metallic silver as a reducing agent in the volumetric estimation of —. G. Edgar and A. R. Kemp. *J. Amer. Chem. Soc.*, 1918, 40, 777—784.

Ferric sulphate in sulphuric acid solution is quantitatively reduced to ferrous sulphate by the action of metallic silver if a soluble thiocyanate is present. The solution is treated with 3–5 grms. of metallic silver and with ammonium thiocyanate in excess of that necessary to precipitate the silver dissolved in the reaction. The dark red solution is shaken in the cold until it becomes quite colourless, is then filtered and the filtrate treated with silver nitrate and titrated with standard permanganate. If the reacting mixture is boiled, reduction is effected more quickly. An alternative method consists in adding measured quantities of standard ammonium thiocyanate and silver nitrate solutions and after titrating with permanganate, determining the excess of silver nitrate in the solution by means of the standard ammonium thiocyanate. Test measurements show that the methods give accurate results. The use of silver and thiocyanate has certain advantages over other methods of estimation in that the thiocyanate shows when the ferric iron is completely reduced, that metallic silver is ordinarily quite free from iron, making blank determinations unnecessary, and that silver has no reducing action on titanium, whilst vanadium is reduced sharply to the quadrivalent state and may consequently be easily corrected for.—H. M. D.

Chlorine; Determination of — in the presence of organic matters (gastric juice, blood, milk, etc.). Sirot and Joret. *Ann. Chim. Analyt.*, 1918, 23, 109—113.

To determine total chlorine in gastric juice, 20 c.c. of the liquid is treated with 20 c.c. of a reagent containing 10 grms. of picric acid and 25 grms. of acetic acid per litre; the mixture is diluted to 100 c.c., filtered, and the chlorine titrated in the filtrate by Volhard's method. Combined chlorine (organic and inorganic) is determined in the same way after the liquid has been evaporated to expel free hydrochloric acid and then diluted with water. Fixed chlorine (inorganic) is determined in the ash of the sample. Sodium metaphosphate is a better clarifier than picric acid in the case of blood; 20 c.c. of the sample is treated successively with 75 c.c. of water, 10 drops of nitric acid, 20 c.c. of 5% sodium metaphosphate solution, and 1.5 c.c. of acetic acid, the mixture is diluted to 200 c.c., filtered, and the chlorine titrated in an aliquot portion of the filtrate. The picric acid reagent mentioned, sodium metaphosphate, or basic lead acetate may be used for clarifying milk previous to the determination of the chlorine present. (See also *J. Chem. Soc.*, July, 1918.)—W. P. S.

Fluorine; Gravimetric and volumetric determination of — as thorium fluoride. F. A. Gooch and M. Kobayashi. *Amer. J. Sci.*, 1918, 45, 370—376.

In the method described by Pisaní (this *J.*, 1916, 709) the fluoride solution should contain from 0.12 to 1.2 gm. of free acetic acid per 100 c.c., and the quantity of standardised thorium nitrate solution added must be such that the excess of thorium does not exceed by more than 50% the quantity required

for precipitation. The precipitated thorium fluoride is collected after a few hours, washed by decantation with very dilute acetic acid, and ignited to thorium oxide; the weight of the latter is a measure of the thorium fluoride, $\text{ThF}_4 \cdot \text{H}_2\text{O}$. Alternatively, the excess of thorium nitrate in the filtrate may be determined by precipitation as oxalate and titration of the latter with permanganate. In dealing with unknown quantities of fluorine, a small quantity of the thorium nitrate solution is treated with the fluoride solution until a distinct turbidity is produced; twice as much thorium nitrate is required, in proportion, to produce this turbidity as is necessary to precipitate the fluoride and leave an excess of about 50% of thorium in the solution. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Combustions of substances containing nitrogen; Rapid organic —. H. L. Fisher and A. H. Wright. J. Amer. Chem. Soc., 1918, 40, 868–869.

In effecting rapid organic combustions of nitrogenous substances, using cerium oxide as a catalyst, with subsequent layers of copper oxide and a mixture of lead peroxide and red lead, trouble may be encountered owing to the formation of copper nitrate especially as the neighbouring lead oxide layer has to be maintained at $300^\circ\text{--}320^\circ\text{C}$.; when a tube is used several times it may even become choked with basic copper nitrate. If copper oxide is used and if it is desired to make several combustions with a tube it is necessary either to renew the copper oxide each time or so to modify the procedure as to ensure the complete decomposition of any copper nitrate after each combustion. It is also found advantageous to use the cerium oxide deposited on pumice instead of on asbestos.—D. F. T.

Analysis; Graphic methods of —. H. Gradenwitz. Chem.-Zeit., 1918, 42, 221.

GRAPHS are given by means of which the composition of ternary mixtures may be ascertained. In the case of a mixture of formaldehyde, methyl alcohol, and water, the formaldehyde is determined in the usual way and the sp. gr. of the mixture is taken; these data being known, the percentage of methyl alcohol is found from the graph. With a mixture of ethyl acetate, alcohol, and water, the sp. gr. and the volume of ethyl acetate which separates when 100 c.c. of the mixture is shaken with 100 c.c. of water are determined; the percentage quantities of the three constituents are then read on the graph. (See also J. Chem. Soc., July, 1918.)—W. P. S.

Calculation of the excess of air used in combustion. Hassreidter. See IIa.

Nature of the cellulose of cereal straw. Heuser and Haug. See V.

Colour reaction of mechanical wood pulp or the incrusting substances of wood with phenylhydrazine hydrochloride. Jentsch. See V.

Apparatus for the determination of nitric acid by the Schulze-Tiemann method. Leuchs. See VII.

Determination of carbon dioxide in carbonates by Dittrich's method. Von Horvath. See VII.

Adsorption of sodium gold chloride by charcoal and the estimation of gold in sea water. Koch. See VII.

Use of Brinell ball in testing [hardness of] constructional materials. Le Chatelier and Bogitch. See VIII.

Rapid determination of total carbon in steel and cast iron. Sernagiotto. See X.

Estimation of oxygen in copper. Oberhoffer. See X.

Analysis of white metals. Drawe. See X.

Rapid determination of resins in soap. Fortini. See XII.

Examination of oil varnishes. Smit-Addens. See XIII.

Determination of free sulphuric acid in leather. Strunk and Matthes. See XV.

Mechanical and physical analysis of soils. Richter. See XVI.

Determination of citric-soluble phosphoric acid in Thomas slag. Hartleb. See XVI.

Water content of true final molasses. Prinsen Geerligs. See XVII.

Polarisation of acidified solutions of beet molasses. Andrlik. See XVII.

Determination of sucrose in cane molasses by Walker's method, using dry basic lead acetate for the preliminary clarification. Walker. See XVII.

Gravimetric determination of glucose (reducing sugars) in molasses. Norris and Brodie. See XVII.

Determination of lime in products of [beet] sugar factories. Vermehren. See XVII.

Detection of eider in wine. Medlinger and Michel. See XVIII.

Estimation of various forms of nitrogen in raw beef, including the products of hydrolysis of some of the proteins. Thrum and Trowbridge. See XIXa.

Detection of arbutin. Salomon. See XX.

PATENTS.

Oil-tester [for determining the flash-point]. C. J. Tagliabue, Brooklyn, N.Y., Assignor to C. J. Tagliabue Manufacturing Co. U.S. Pat. 1,263,145, Apr. 16, 1918. Date of appl., Aug. 14, 1915.

An open oil cup is mounted in a water bath, and a bracket having a vertical bearing is attached to the outside of the bath. A gas tube is mounted to rotate

In the bearing and the upper end of the tube is bent horizontally and carries a burner tip which is thus movable over the top of the oil cup in a horizontal plane. Means are provided on the tube and bracket to maintain the burner at a constant predetermined height, and a stop-cock is provided for adjusting the size of the flame.—W. F. F.

Drying apparatus. Eng. Pat. 114,620. See I.

Process for testing the wearing quality of wool.
Ger. Pat. 302,808. See V.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Allen. Centrifugal mixers, washers, etc. 10,279 and 10,280. June 21.

Barbet et Fils et Cie. 10,116. See XX.

Beeton, and Trufood, Ltd. Drying organic substances. 10,057. June 18.

Birkedal and Nielson. Apparatus for mixing liquid or gaseous substances. 10,685. June 28. (Denmark, Apr. 24, 1917.)

Brooks. Regenerative oven or furnace. 10,659. June 28.

Brownlow. Centrifugal separators. 10,231. June 21.

Drysdale, Drysdale and Co., and Young. Straining or screening apparatus for liquids. 10,244. June 21.

Drysdale, Drysdale and Co., and Young. Strainers or screens for liquids. 10,245. June 21.

Elektro-Osmose A.-G. 10,453—10,460. See XI.

Fullager, Reavell, and Kestner. Evaporator and Engineering Co. Evaporators. 10,061. June 18.

Furness. Filter-press plate for filtering acid, etc. 9921. June 17.

Grant. Raising liquids of low viscosity. 10,333 and 10,334. June 22.

Grant. Raising liquids, semi-liquids, and slimes. 10,335. June 22.

Morson and Son, and Roy. Means for carrying out catalytic or contact reactions between gases and/or vapours. 10,536. June 26.

Rosborg. Furnaces. 9953. June 17.

Shakespeare. Means for heating or melting solids, semi-solids, or liquids. 10,091. June 19.

Walker. Pulverising-mills. 10,474. June 25.

Wallwin. Gas-heated furnaces or mudles. 10,589. June 27.

Walpole. Means for regulating humidity of drying-kilns, hot-houses, etc. 10,281. June 21.

COMPLETE SPECIFICATIONS ACCEPTED.

8616 (1917). Allen. Roller grinding-mill. (107,201.) July 3.

8686 (1917). Adam. Method of separating crystals from solutions. (116,749.) July 3.

9465 (1917). Barbet et Fils et Cie. See XVIII.

10,865 (1917). Persch. Recovery by condensation of volatilised solvents. (116,590.) June 26.

10,908 (1917). British Dyes, Ltd., Turner, and Eastwood. Stopper for carboys or the like. (116,798.) July 3.

11,795 (1917). Boulton. Drying-apparatus for use in drying fruit, herbs, vegetables, seeds, chemicals, fibre, and the like. (116,606.) June 26.

15,082 (1917). Soc. l'Air Liquide. See VII.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Adam. Purification of coal gas. 10,287. June 21.

Barbet et Fils et Cie. Process for dissociation of heavy oils for production of light spirits. 9961. June 17. (France, June 22, 1917.)

Barbet et Fils et Cie. Continuous rectification of petrols, petroleum, benzoles, etc. 10,341. June 22. (France, July 3, 1917.)

Holmes. Treatment of liquor from plants for purifying gases from producers, etc. 10,208. June 20.

O'Brien. Treatment of liquid hydrocarbon and production of valuable by-product. 10,704. June 28.

Ramage. Extracting bitumen, petroleum, etc., from certain materials. 10,437. June 25.

Silberrad. 10,563. See XX.

Somerville, and South Metropolitan Gas Co. Process for removing carbon monoxide, and manufacture of material therefor. 10,767. June 29.

Spicer (Wells). Production of gas from liquid bodies. 10,055. June 18.

Strache. Gasification of carboniferous substances. 10,352. June 22. (Austria, June 28, 1916.)

Wallwin. 10,589. See I.

Willmer. Manufacture of gas mantles. 10,068. June 18.

Zwillinger. Converting beehive coke-ovens into by-product ovens. 9977. June 17.

COMPLETE SPECIFICATIONS ACCEPTED.

9099 (1917). Bogaerts. See XII.

10,059 (1917). Smith, and Perry and Co. Twin-generator gas plants for manufacture of water-gas containing varying proportions of the component gases. (116,582.) June 26.

15,662 (1917). Toogood, and Dempster and Sons. Manufacture of gas in vertical retorts. (116,831.) July 3.

19,065 (1917). Thompson. See XI.

3447 (1918). De La Devesa. Compounds for increasing the calorific value of coal and like fuel. (116,676.) June 26.

4525 (1918). Easton. Construction of retorts, coke-ovens, and the like. (116,873.) July 3.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Barbet et Fils et Cie. 9961 and 10,341. See II.

Barbet et Fils et Cie. Process for continuous sulphonation of bodies having a benzenic function, such as naphthalene and impure benzenes. 10,117. June 19. (France, June 26, 1917.)

Brewster. Process of nitrating benzol, and apparatus therefor. 10,518. June 26. (U.S.A., Nov. 20, 1917.)

Nitrogen Products and Carbide Co., and Perkin. Treatment of pitch. 10,759. June 29.

O'Brien. 10,704. *See* II.
 Pohlmann. 10,027. *See* XXII.
 Ransford (Cassella und Co.). Manufacture of anthraquinone derivatives. 10,285. June 21.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Imray (Soc. of Chem. Industry in Basle). Manufacture of disazo-dyestuffs. 10,461. June 25.
 Kay and Robinson. Manufacture of intermediate products for preparation of dyestuffs. 10,503. June 26.
 Newton (Bayer und Co.). Manufacture and production of new azo-dyestuffs. 10,682. June 28.
 Ransford (Cassella und Co.). Manufacture of a colour of the anthraquinone series. 10,545. June 26.

COMPLETE SPECIFICATIONS ACCEPTED.

183 (1917). Oman. Method of preparing azo colouring matters from lignine-sulphonic acid or its salts. (103,479.) July 3.
 8329 (1917). Imray (Soc. of Chem. Industry in Basle). Manufacture of acid wool dyestuffs indifferent to copper. (116,530.) June 26.
 8420 (1917). Imray (Soc. of Chem. Industry in Basle). Manufacture of chromin compounds of azo-dyestuffs. (116,535.) June 26.
 8802 (1917). Imray (Soc. of Chem. Industry in Basle). Manufacture of condensation products of gallocyanine dyestuffs with amines. (116,754.) July 3.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bawtree and Hadfield. Composition for rendering walls of cardboard containers impervious to fluid or otherwise preserving their contents. 10,177. June 20.
 Clayton, Huebner, Williams, and Manchester Oxide Co. Process of treating celluloses. 10,567. June 27.
 Clayton, Huebner, Williams, and Manchester Oxide Co. Manufacture of parchmentised paper, vulcanised fibre, etc. 10,568. June 27.
 Danin. Solution for treating aeroplane canvas, etc. 10,258. June 21.
 Dreyfus. Manufacture of cellulose esters, etc. 10,174. June 20.
 Dreyfus. Manufacture of cellulose esters and further transformation products thereof. 10,667. June 28.
 Dreyfus. Manufacture of cellulose derivatives. 10,755. June 29.
 Thompson (Underwood and Illston). Treatment of waste liquors from wool scouring, etc. 10,513. June 26.
 Van Wessen. Manufacture of fibrous material from sawdust and wood waste. 10,616. June 27. (Holland, Dec. 23, 1915.)
 Van Wessen. Manufacture of fibrous material from wood, etc. 10,681. June 28. (Holland, Jan. 29, 1918.)
 Wheatley. 9912. *See* XV.

COMPLETE SPECIFICATION ACCEPTED.

9034 (1917). Hey. Method of cleaning, carbonising, and sterilising raw wool. (116,763.) July 3.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Calico Printers' Assoc., and Fourneaux. Production of black upon vegetable textile fibres, silk fibres, or mixtures of same. 10,298. June 22.
 Calico Printers' Assoc., Fothergill, and Wilson. Treatment of insoluble natural gums for production of thickenings for calico, etc., printing and finishing, etc. 10,299. June 22.

COMPLETE SPECIFICATIONS ACCEPTED.

9022 (1917). Calico Printers' Assoc., and Fourneaux. Production of black upon vegetable fibres. (116,562.) June 26.
 18,123 (1917). Crayton. Dyeing of slubbing yarn and the like, and apparatus therefor. (116,652.) June 26.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Beedle and Bradford. Process for obtaining pure zirconium oxide. 10,314. June 22.
 Calvert. Manufacture of cyanide and cyanogen compounds. 10,181. June 20.
 Chance and Hunt, Gidden, and Ragg. Manufacture of arsenic chloride. 10,288. June 21.
 Davis. Apparatus for concentration of sulphuric, etc., acids. 10,127. June 19.
 Deutsche Gold- und Silber-Scheideanstalt vorm. Rössler. Manufacture of sodium percarbonate. 10,282. June 21. (Germany, May 18, 1917.)
 Deutsche Gold- und Silber-Scheideanstalt vorm. Rössler. Manufacture of alkali percarbonates. 10,401. June 24. (Germany, June 25, 1917.)
 Dutt and Dutt. Process for manufacture and production of manganese oxide. 10,478. June 25.
 Field, and Metals Extraction Corporation. Purification of metallic solutions. 10,708. June 28.
 Furness. 9921. *See* I.
 Hodgkinson. 9952. *See* XXII.
 Matheson. Manufacture of acetic acid. 10,071. June 18.
 Matheson. 10,073. *See* X.
 Wilton. Apparatus for preparation of sulphate of ammonia. 10,452. June 25.
 Wyld. Apparatus for distillation or treatment of ammoniacal liquors, etc. 10,162. June 20.

COMPLETE SPECIFICATIONS ACCEPTED.

7015 (1917). Levin. Manufacture of a boron derivative of pyrophosphoric acid. (116,735.) July 3.
 15,082 (1917). Soc. l'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude). Process for the separation by liquefaction and rectification of the elements of the air. (114,817.) July 3.
 1403 (1918). Norske Aktieselskab for Elektrokemisk Industri, Norsk Industri-Hypotekbank. Process for the manufacture of aluminium compounds poor in iron. (112,948.) June 26.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Anderson. Means for coating pottery or earthenware with glazing-mixture. 10,652. June 28.

Baber, Baber, and Jones. Fast-firing furnace for manufacture of bricks. 10,656. June 28.

Roirant. Glass-melting furnaces. 10,572. June 27. (France, July 12, 1917.)

IX.—BUILDING MATERIALS.

APPLICATIONS.

Baber, Baber, and Jones. 10,656. *See* VIII.

Bottomley. 10,213. *See* XIII.

Pennington and Pennington. Cement. 10,148. June 20.

Williams. Manufacture of concrete. 10,377. June 24.

COMPLETE SPECIFICATION ACCEPTED.

8602 (1917). Dieker (Lambert Process Co.). Method of burning bricks and the like. (116,745.) July 3.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Bennett. Steel-heating furnace. 10,026. June 18. (U.S.A., Aug. 16, 1917.)

Clegg, and Greenwood and Batley. Annealing-furnaces. 10,379. June 24.

Davies and Thomas. Pickling iron and steel plates or sheets. 10,155. June 20.

Harris and Wilkes. Reverberatory furnaces for use in recovery of zinc from dross. 10,553. June 26.

Herdman. Manufacture of mineral wool. 10,283. June 21.

Herdman. Manufacture of slag wool. 10,538. June 26.

Isherwood. Recovery of tin from waste of tin-plate. 10,684. June 28.

Knowles. Recovering scrap steel and dolomite discharged with slag from Siemens open-hearth, etc., furnaces, and disposing of slag. 10,469. June 25.

Lord. Metal-melting furnaces. 10,216. June 20.

Lowenthal. Electrodeposition of zinc and nickel. 10,491. June 26.

Matheson. Process of recovering mercury. 10,072. June 18.

Matheson. Process of oxidising mercury. 10,073. June 18.

Morfett. Furnaces for melting lead, etc. 10,763. June 29.

Stabilimenti Biak-Ing. Pouchain. Metal alloy containing manganese. 10,209. June 20. (Italy, Mar. 9.)

Stabilimenti Biak-Ing. Pouchain. Metal alloy. 10,210. June 20. (Italy, Mar. 16.)

Sumitomo Chukosho, Ltd. Magnet steel. 10,531. June 26. (Japan, June 15, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

16,309 (1916). Reichstein. Rust-preventing process. (103,474.) July 3.

15,116 (1917). Bagtiardi. Process of annealing high-speed steel. (116,829.) July 3.

15,254 (1917). Keith and Keith. Crucible furnaces. (116,636.) June 26.

16,131 (1917). Stabilimenti Biak-Ing. Pouchain. Manufacture of metal alloys containing nickel. (111,290.) June 26.

747 (1918). Bagley. Process and apparatus for removing molten slag from open-hearth steel furnaces by means of air or steam blast. (116,663.) June 26.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

C. I. Syndicate, and Jenkins. Electrolytic cells. 10,658. June 28.

East Stratford Works, and Jenkins. Electrolytic cells. 10,205. June 20.

Elektro-Osmose A.-G. (Graf Schwenin Ges.). Charging material to electro-osmotic apparatus for removing liquids from substances. 10,453. June 25. (Germany, Oct. 20, 1917.)

Elektro-Osmose A.-G. Electrodes for electro-osmotic processes. 10,454. June 25. (Germany, Oct. 20, 1917.)

Elektro-Osmose A.-G. Electro-osmotic process for removing water from materials. 10,455. June 25. (Germany, Oct. 20, 1917.)

Elektro-Osmose A.-G. Apparatus for electro-osmotically removing water. 10,456 and 10,459. June 25. (Germany, Oct. 20, 1917.)

Elektro-Osmose A.-G. Apparatus for electro-osmotically removing liquids from materials. 10,457. June 25. (Germany, Oct. 20, 1917.)

Elektro-Osmose A.-G. Apparatus for electro-osmotically removing water from materials. 10,458. June 25. (Germany, Oct. 20, 1917.)

Elektro Osmose A.-G. Electro-osmotically removing water from materials. 10,460. June 25. (Germany, Dec. 12, 1917.)

Lowenthal. 10,491. *See* X.

Peto. Electric storage batteries or accumulators. 10,031. June 18.

White (Industrial Electric Furnace Co.). Electric furnaces. 10,183. June 20.

COMPLETE SPECIFICATIONS ACCEPTED.

8343 (1917). Muller. Electric insulating materials. (116,532.) June 26.

15,541 (1917). Cotte. Electrical accumulators. (11,107.) July 3.

19,065 (1917). Thompson. Manufacture of carbon electrodes. (116,661.) June 26.

551 (1918). Kilburn (Norske Aktieselskab for Elektrokemisk Industri, Norsk Industri-Hypotekbank). Manufacture of carbon electrodes. (116,853.) July 3.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Paulin. Manufacture of cleansing material. 10,537. June 26. (France, Oct. 23, 1917.)

Powling and Powling. Apparatus for extracting fat from bones, etc. 10,129. June 19.

Sharp. Manufacture of soap. 10,361. June 24.

Witter. 10,424. *See* XIII.

Wynne. Refining and treatment of oils, fats, greases, etc. 10,302. June 22.

COMPLETE SPECIFICATION ACCEPTED.

9099 (1917). Bogaerts. Method of treating oils. (116,765.) July 3.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Bottomley. Priming or paint for concrete or cement surfaces, etc. 10,213. June 20.

Bromley. Destructible printing-ink pigment. 10,525. June 26.

Grozier. Reclaiming used printers' roller composition. 10,668. June 28. (Australia, Jan. 3.)

Witter. Process for treating linseed oil residual fatty acids, and utilising same as oil for paint or oxidation for manufacture of linoleum, etc. 10,424. June 25.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Wheatley. Process for heat-vulcanising rubber-proofed fabric. 9913. June 17.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

La Chevardière de la Grandville, and Roy. Glue. 10,396. June 24. (France, Dec. 10, 1917.)

Wheatley. Process for proofing or impregnating leather, textile material, etc. 9912. June 17.

COMPLETE SPECIFICATION ACCEPTED.

12,800 (1917). Tunnell. Vegetable glue or adhesive. (116,620.) June 26.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Parker and Partington. Fertilisers. 10,528. June 26.

COMPLETE SPECIFICATION ACCEPTED.

8858 and 18,802 (1917). Robinson. Manufacture of fertilisers. (116,758.) July 3.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Calico Printers' Assoc., and others. 10,299. *See* VI.

McLaurin. Process of making dextrine. 10,532. June 26.

McLaurin. Dextrine. 10,533. June 26.

COMPLETE SPECIFICATION ACCEPTED.

6824 (1917). McNeill. Process of and apparatus for macerating crushed sugar cane. (116,521.) June 26.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Desborough, Henley, Reilly, and Thaysen. Manufacture of fermentation products. 10,219 and 10,220. June 20.

COMPLETE SPECIFICATION ACCEPTED.

9465 (1917). Barbet et Fils et Cie. Process and apparatus for distilling in multiple effect alcoholic liquors and the like. (107,599.) June 26.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Adenauer. Preservation of foodstuffs such as sausages, etc. 10,511. June 26.

Beeton, and Trufood, Ltd. 10,057. *See* I.

I.—GENERAL ; PLANT ; MACHINERY.

Chemical apparatus; Use of wood in —. A. W. Schorger. *Met. and Chem. Eng.*, 1918, 18, 528—531.

THE results of an inquiry by the U.S. Forest Products Laboratory show that wood is attacked by most of the inorganic acids, a strong solution of the acid dissolving the cellulose, while more dilute acids have slight action on the cellulose but attack the lignin, causing disintegration of the wood. For pickling tanks in which hydrochloric acid or sulphuric acid (up to 5% concentration) is used, cypress wood appears to be the best. Pine, fir, or Californian redwood is satisfactory for the storage of hydrochloric acid, and particularly if coated with pitch or asphalt, but no wood will withstand for any length of time the action of nitric or sulphuric acids. For chemical processes generally cypress has the longest life, followed by yellow pine. Paraffined hard maple is mentioned as suitable for filter-press plates where acid liquors have to be filtered.

—C. A. K.

Filter-presses; Washing in —. D. R. Sperry. *Met. and Chem. Eng.*, 1918, 18, 520—522.

THERE are certain cases in which it is desirable to have the wash-water connection on the filter-press separate from the feed connection. It would be possible to put in a duplicate feed channel composed of a separate set of grommets, but this is too expensive. The use of frames is necessary in the recessed type, and a channel is formed by providing an eye in the upper corner opposite the one occupied by the grommet. In the flush type of plate without grommet feed a separate inlet for wash water is provided by a second similar feed channel in the opposite corner, and where the washings are required separate from the filtrate, they are collected and run off by a channel at the base of the plates, opposite to the outlet cocks, which are turned off during the washing process. One of the disadvantages of simple washing is that a hollow space must be left in the cakes so that the wash water can penetrate the cake thoroughly and this presupposes an even deposit of cake on the plate. In practice this is difficult to attain.

—C. A. K.

Corrosion of gas and water pipes. Medinger. *See X.*

PATENTS.

Catalytic material employed for the promotion of synthetic chemical reactions; Preparation of —. H. Lane, Ashford, Middlesex. *Eng. Pat.* 115,924, June 11, 1917. (*Appl. No.* S295 of 1917.)

A METALLIC circular air-tight pan, *a, b*, is provided with a vertical shaft, *c*, carrying two arms, *h, i*, which are curved helically in a horizontal plane. The arms carry sliding teeth, *j*, which rest on the bottom of the pan, and the shaft, *c*, may be rotated in either direction so that the material in the pan may be forced outwards or inwards as desired. The material is fed from a hopper, *q*, provided with an oscillating valve, *r*, and finally discharged through the column, *u*. The pan is heated by an annular burner ring, *s*. Oil or other coating substance for the catalyst is first fed into the apparatus to seal the lower outlet of the column, *n*, and a reducing gas is injected through the pipe, *vc*. The raw material is then fed from the hopper, *q*, and heating is continued till water ceases to be condensed in the condenser, *u*. The rotation of the

shaft, *c*, is then reversed, and the material thereby collected towards the centre of the pan and discharged into the coating liquid. The apparatus is

applicable for the manufacture of finely divided reduced nickel for the production of stearin by hydrogenation of oils.—W. F. F.

Catalytic or contact reactions; Means for carrying out — between gases and/or vapours. C. S. Roy, Chingford, and T. Morson & Son, Ltd., London. *Eng. Pat.* 116,151, June 2, 1917. (*Appl. No.* 7939 of 1917.)

WITHIN a metal casing fitted with a dome-shaped cover with a flue at the top is a series of horizontal tubes of suitable material, *e.g.*, copper, porcelain, for containing the catalyst. The tubes are open at both ends, being fitted into the sides of the casing. If the catalyst is in the form of pumice, pieces of brick, and the like, with or without the addition of other substances, it is disposed partly in shallow boats of half cylindrical form and partly on the floor of the tube itself. The boats are each connected to a header adapted to move in a chamber enclosing the inlet ends of the tubes, the header being controlled by means of a rack and pinion or other suitable means. By moving the header it is possible to adjust the amount of surface of catalyst exposed and also to expose fresh surface to the action of the gases. If the catalyst is in the form of metallic gauze, discs or coils of the gauze are employed, each fitting into a short copper cylinder. The cylinders rest on boats in the tubes and by means of an arrangement of pins on the cylinders fitting into slots of different lengths in the boats—increasing in length from the supply ends of the tubes—the spacing of the cylinders in the tubes can be adjusted from the outside. The tubes may be heated before starting the reaction by means of gas burners at the bottom of the casing, and during the reaction the temperature of the catalyst can be controlled by a supply of steam admitted into the casing. On leaving the tubes, the reaction products are cooled rapidly, *e.g.*, by cooled baffle plates, or by passing through tubes surrounded by water or steam. Means are provided for sampling the reaction products on leaving the tubes and an explosion door may be fitted to the apparatus, and a preheater at the inlet end.

—L. A. C.

Condensing exhaust steam and other vapours, and setting up an induced current of air or gases to obtain a vacuum; Apparatus for —. J. Tinsley, Beaufort, Brecon. Eng. Pat. 116,769, June 26, 1917. (Appl. No. 9133 of 1917.)

Cold water supplied to the pipe, 4, is discharged through two annular passages, 5, 6, into the conical guides, 7, 8, open at the ends. Exhaust steam or other vapour enters by the pipe, 1, and passes around the water nozzle and also through the central passage, 10, and annular passage, 9. The

water and steam jets thus surround each other alternately. V-shaped pieces are cut out of the lower edges of the guides, 7, 8, and V-shaped blades, 11, 12, extending nearly to the axis, are inserted as shown. The lower edges of the guides are also serrated so that the water and steam are divided into a number of streams and intimately mixed. The steam is thus effectively condensed and a high vacuum is obtained.—W. F. F.

Transmission or exchange of heat between fluids; Apparatus for —. A. D. Harrison, Marple, Cheshire. Eng. Pat. 116,786, July 17, 1917. (Appl. No. 10,334 of 1917.)

In a heat-exchanging apparatus, particularly applicable for cooling oil, shown in plan in the figure, a horizontal plate, 6, is provided on its two sides with ribs, 7 and 7', respectively, and with four apertures, 8, 9, 10, 11, formed by a flange, 12. The cooler is built up of a number of such elements superposed, with a flat plate between each pair,

having apertures corresponding to 8, 9, 10, 11, the whole being clamped together by bolts, 3. Each rib, 7, thus forms a circuitous zigzag passage as shown, the two ends of which communicate with the vertical conduits, 8, 9, which form the inlet

and outlet for oil. Similarly each rib, 7', forms a circuitous passage communicating with the common inlet, 10, and outlet, 11, for water, the two liquids flowing in opposite directions on the two sides of the plate, 6. In a modification, the passages for the oil and water may be continuous spirals and the oil inlet and water outlet may be central instead of at the sides. In another modification, the zigzag passage may be rectilinear instead of curved, the common inlets and outlets being at the four corners of the column. In a further modification the passages may be so arranged that the adjacent elements are connected in series instead of in parallel. A method of constructing the circulating elements is also described.—W. F. F.

Volatile constituents; Method of separating —. E. O. Barstow and T. Griswold, jun., Midland, Mich. U.S. Pat. 1,261,005, Apr. 2, 1918. Date of appl., Dec. 21, 1914.

In a method of removing the residual solvent from an extracted material, the material is moved in contact with a counter-current of steam so that a mixture of steam and vaporised solvent is obtained in varying proportions at different points. The sensitive element of a thermostat is placed at a selected point in the current and controls the steam inlet valve so that a constant temperature is maintained at that point.—W. F. F.

Extracting apparatus. D. C. Reynolds, Philadelphia, Pa. U.S. Pat. 1,253,470, Apr. 23, 1918. Date of appl., Mar. 27, 1917. Renewed Feb. 27, 1918.

The apparatus comprises a series of extracting tanks, a series of storage tanks, an evaporator tank, and a circulating pump. Each extracting tank has a horizontal partition a short distance above the bottom, with central aperture which is partially obstructed by a trap or seal. The trap permits liquid to flow through the aperture only in one direction. A series of tubes extend through the partition to a point near the top of the tank, and below the partition is a steam coil to heat the contents of the tank. The extracting tanks are filled with the material to be extracted, and water is introduced. The water is heated to boiling by the steam coil and circulates up through the tubes and down over the material in the tank. It may be passed from the lower part of the tank to the storage tanks and thence again introduced into the upper part of the extraction tank by means of the pump. When the extract is sufficiently concentrated, it is passed to the evaporator tank, which is of similar construction to the extraction tank.

—J. H. P.

Volatile liquids; Process for recovering the vapours of —. K. E. Barth, Charlottenburg, Assignor to Berlin-Anhaltische Maschinenbau A.-G., Berlin, Germany. U.S. Pat. 1,264,479, Apr. 30, 1918. Date of appl., Apr. 7, 1914.

A GASEOUS mixture containing inflammable vapours is cooled to condense the vapours, the condensed product is separated, and the remainder of the mixture diluted with a suitable gas to insure non-explosiveness.—J. H. P.

Fire extinguishing compound. C. J. Strosacker, Assignor to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,261,067, Apr. 2, 1918. Date of appl., June 6, 1916.

A MIXTURE of carbon tetrachloride and a relatively small amount, e.g., 5 to 10%, of a monohalogen derivative of methane, e.g., monochloro- or monobromomethane or both.—J. H. P.

Fireproofing solution. G. E. Ferguson, New York, Assignor to Pyrene Manufacturing Co., D. U.S. Pat. 1,261,736, Apr. 2, 1918. Date of appl., Sep. 30, 1915.

The solution comprises a solvent containing a volatile substance and zinc phosphate and zinc hydroxide. For example zinc phosphate and zinc chloride are treated with sufficient ammonia to convert the chloride into hydroxide and dissolve the hydroxide thus formed.—J. H. P.

Distillation apparatus; Sectional —. G. B. Furman, East Orange, N.J. U.S. Pat. 1,265,318, May 7, 1918. Date of appl., Aug. 26, 1917.

The apparatus comprises a still and a number of separators in series. The first separator is connected to the still, and a return connection is provided between this separator and the still, as well as another connecting pipe to return any condensate from the pipe joining two separators to the above-mentioned return connection.—J. H. P.

Dryer. F. J. Bowman, Cleveland, Ohio. U.S. Pat. 1,265,298, May 7, 1918. Date of appl., Feb. 24, 1914.

The apparatus consists of a vertical tower containing a series of distributing devices comprising parallel spaced angle plates having the apex of the angles projecting upwards. Some of the plates terminate in inclined end plates resting against the walls of the tower. Hot air is passed upwards through the tower, and a blower discharges the air from the top of the tower downwards through a conduit into a settling tank for the fine material.—J. H. P.

Liquid separator; Centrifugal —. C. B. Dalzell, Assignor to D. H. Burrell & Co., Little Falls, N.Y. U.S. Pat. 1,265,061, May 7, 1918. Date of appl., Mar. 27, 1917.

The space between the rotating separator bowl and the stationary case is free from obstructions which would prevent the air from rotating with the bowl. Blades fixed on the lower portion of the bowl cause an upward flow of air between the bowl and the case.—J. H. P.

Solutions; Method of separating crystals from —. W. G. Adam, London. Eng. Pat. 116,749, June 16, 1917. (Appl. No. 8686 of 1917.)

The hot saturated solution is supplied to a number of transverse troughs at the top of a tower, and overflows on to transverse horizontal plates and then splashes on to a series of transverse bars of glass arranged "in staggered form" and extending down the tower. The solution is cooled by an upward current of air, which is induced by the heating of the air in the tower by the hot solution, and large crystals are formed, which collect in a vessel below. The temperature in the tower may be controlled by regulating the air exit, or by having different amounts of water of crystallisation.—W. F. F.

Cooling, humidifying, and filtering air or the like; Apparatus for —. H. F. Brown, Sheffield. Eng. Pat. 116,839, July 14, 1917. (Appl. No. 16,640 of 1917.) Addition to Eng. Pat. 112,653, Jan. 1, 1917 (this J., 1918, 114 A).

In apparatus of the type described in the principal patent, in which a perforated sprinkler arm rotates close to the upper ends of a number of parallel vertical plates, the rotating arm is provided on its trailing side with a flange which covers a number

of spaces between the plates to which water has just been supplied. The passage of air through these spaces is thus prevented until all the free moisture has fallen through the spaces and drained from the plates.—W. F. F.

Drying [and disintegrating] machine. T. C. Kelly, Cincinnati, Ohio. U.S. Pat. 1,261,132, Apr. 2, 1918. Date of appl., Nov. 22, 1916.

The machine comprises a long closed conduit through which the material is passed by means of intermeshing screw conveyors. The conveyors are driven separately and a drying fluid is passed through the conduit, which may be heated.

—J. H. P.

Grinding ores and other materials; Mill for —. W. H. Janney, Hurley, N. Mex. U.S. Pat. 1,261,398, Apr. 2, 1918. Date of appl., May 1, 1917.

A BARREL-SHAPED container mounted to rotate on horizontal trunnions is provided with a transverse central vertical partition which is double walled and provided internally with partitions forming spiral passages. External scoops are provided at the periphery of the partition, so that as the container rotates, material is taken from a receptacle below and fed into the spiral passages. The material is discharged alternately into the two compartments of the container near the axis, at about the level of the material in the container. Transverse passages are provided in the partition to equalise the material in the two compartments and the ground material is discharged through the hollow trunnions.—W. F. F.

Roller grinding mill. H. Allen, Gainesville, Fla., U.S.A. Eng. Pat. 107,204, June 15, 1917. (Appl. No. 8616 of 1917.) Under Int. Conv., June 15, 1916.

The material is ground between a horizontal cylindrical roller and a stationary surrounding egg-shaped member, the grinding surfaces of both being serrated. The hollow member is supported on two horizontal pivots parallel to the axis of rotation, one on each side at the bottom, the roller being in its lower enlarged portion. One of the pivots is fixed and the other is adjustable by means of a set screw acting on a lever carrying the pivot, so that the hollow member may be adjusted eccentrically to the roller to vary the distance between the grinding surfaces. The hollow member and roller are both made in flat transverse sections which are then built up, and an adjustable baffle-plate is interposed between two sections of the hollow member to vary the rate of feed longitudinally through the mill. The material is fed and delivered at opposite ends of the roller. Radial passages for air may be provided between the sections of the hollow member.

—W. F. F.

Crushing machine; Rotating-ring —. E. B. Symons, Chicago, Ill. U.S. Pat. 1,264,347, Apr. 30, 1918. Date of appl., Nov. 9, 1914.

In a crushing machine having a rotating roller within and supporting a ring, the material is fed to the inner surface of the ring near its middle line. The ring is hollowed internally and the ring and roller are given a reciprocating movement to and from one another to crush the material. The material is fed transversely across the face of the ring by a series of separate steps of progressively diminishing length and velocity from the centre outwards.—W. F. F.

Gas-dryer. H. A. Brassert, Chicago, Ill. U.S. Pat. 1,264,253, Apr. 30, 1918. Date of appl., Dec. 8, 1915.

Gas enters tangentially at the top of a vertical casing and passes down outside a concentric vertical pipe. A number of rows of baffles, arranged circularly, project downwards from the bottom of the pipe and are supported from the wall of the casing so as to divert the gas into the inner pipe through which it passes upwards.—W. F. F.

Dust catcher for cleaning gases. C. Heine, Düsseldorf. Ger. Pat. 302,973, Nov. 21, 1916. Addition to Ger. Pat. 230,182 (see Fr. Pat. 419,933; this J., 1911, 120).

THE gas enters at the bottom of the annular space between two concentric vertical cylinders, flows upwards in a spiral path, and leaves through the inner cylinder which it enters at the top. In its passage, the gas beats against vertical radial baffles fixed alternately to the inner and outer cylinder, whereby dust particles are arrested and fall into the conical base of the apparatus.—H. J. H.

Gases; Apparatus for the electrical separation of suspended particles from —. G. A. Krause, München. Ger. Pat. 303,078, June 1, 1913.

THE gas is passed through a casing closed below by a metal plate on which a series of glass jars is placed. Plate electrodes connected to the positive pole of a source of current pass through the top of the casing, but insulated therefrom, and project into the jars. The metal plate below the jars is connected to the negative pole of the source of current, so that the jars act as condensers of the Leyden jar type. Suspended particles in the gas become charged and are deposited in the jars.

Filtering apparatus and system. W. C. Graham, Loveland, Colo. U.S. Pat. 1,264,635, Apr. 30, 1918. Date of appl., July 26, 1915. Renewed Sep. 25, 1917.

SEVERAL tubular shafts extend through a casing and carry rotary filter elements, the interiors of which communicate with the interiors of the shafts. The filter elements on each shaft pass between and close to those on the adjacent shaft, so that material adhering to the filters is displaced during rotation.

—J. H. P.

Engine for low temperature expansion. E. A. W. Jefferies, Assignor to Jefferies-Norton Corporation, Worcester, Mass. U.S. Pat. 1,264,871, Apr. 30, 1918. Date of appl., Dec. 1, 1915. Renewed Jan. 19, 1918.

THE cylinder of an engine in which compressed or liquefied gases are made to expand at a low temperature for the production of extreme cold, consists of a metal casing provided with a lining having a low heat capacity, so as to prevent material absorption of heat by the surfaces with which the expanding gases come in contact. This lining is mainly composed of fibrous material and a binding agent, with or without the addition of graphite, and may be compounded by the application of heat and pressure.—C. A. M.

Centrifugal machine. H. Delvenne, Grevenbroich. Ger. Pat. 302,664, Oct. 3, 1916.

THE upper end of the vertical shaft of the centrifuge carries a hub which is connected to the shaft of the motor above by a ball and socket joint; the upper end of the motor shaft works in a collar bearing. The motion is transmitted by means of a flanged coupling disc secured to the lower end of the motor shaft and provided with rollers which fit in grooves in the hub on the centrifuge shaft.

Liquids; Machine for extracting — from various materials. C. D. Jenkins, Assignor to Peat Coal Ltd., Boston, Mass. U.S. Pat. 1,265,206, May 7, 1918. Date of appl., May 1, 1915.

A HOLLOW cylinder is formed of sections of wood having the grain perpendicular to the cylindrical surface. An eccentric rotating member is arranged within the cylinder so as to press the material against the wall and force the liquid through the pores.—W. F. F.

Settling tank. W. E. Saxe, Inglewood, Cal. U.S. Pat. 1,265,256, May 7, 1918. Date of appl., Oct. 11, 1915.

THE material to be treated is fed through an automatically controlled discharge outlet in a receiving trough into the conical settling tank, which is provided with means for spreading or retarding the movement of the material. The tank is supported by pivoted levers with counterweights, and is provided with an outlet valve which may be locked or unlocked automatically. The liquid outlet is arranged under the spreader, near its centre, so that the outlet flow of liquid is accelerated and the lighter material held in suspension after the heavy matter has been deposited. Converging partitions lead to the liquid outlet and prevent a whirling action.—J. H. P.

Furnace. A. W. Moyer, Belmar, N.J. U.S. Pat. 1,264,961, May 7, 1918. Date of appl., Nov. 5, 1917.

A FURNACE is provided with a removable arched top, and is heated by burners in combustion chambers outside the side walls of the heating chamber and communicating with it by lateral passages through the walls. The hot gases are discharged from the lower part of the heating chamber. The furnace is supported in a cradle comprising transverse girders beneath the hearth, vertical stays to prevent spreading of the side walls, and inclined bracing members attached to the stays and girders. This arrangement does not prevent the removal of the furnace top.—W. F. F.

Bleaching earth [fullers' earth]; Process for increasing the decolorising power of —. L. Kern, Hamburg. Ger. Pat. 305,896, Feb. 2, 1917. Addition to Ger. Pat. 304,076.

THE dried ground earth is treated with gaseous acid (e.g. sulphur dioxide) instead of with liquid acids as described in the original patent. After the treatment the earth may be freed from the sulphur dioxide, etc., by means of a current of warm air.

—C. A. M.

Filling material for reaction towers, washing towers, and the like. H. Petersen, Berlin-Steglitz. Ger. Pat. 302,753, Oct. 22, 1913.

THE filling material consists of hollow rings having the shape of a regular polygon with an odd number of sides, and provided with undulating grooves or channels.

Gases or vapours; Process of separating — from gaseous mixtures. P. Beck, Nordhausen. Ger. Pat. 304,603, June 12, 1917. Addition to Ger. Pat. 302,692 (this J., 1918, 328 A).

GASEOUS mixtures are treated at the ordinary or in some cases at higher temperatures with lignite or lignite products which have been freed from gas. Gases such as sulphur dioxide, hydrogen sulphide, ammonia, chlorine, and cyanogen, are absorbed by lignite which has been freed from gas, and may be recovered by steaming, exhaustion with a pump, or by the passage of an inert medium through the material.—C. A. M.

Solid substances; Apparatus for the continuous solution of —. H. Eberhardt, Wolfenbüttel. Ger. Pat. 304,802, Dec. 16, 1916. Addition to Ger. Pat. 302,641 (this J., 1918, 360 A).

The vessel containing the solvent is enlarged at the top, and the enlargement carries a ring-shaped channel. The heating device is separated from the surrounding wall of the cylinder by a protective jacket, thus forming an annular space in which the sludge can subside. This sludge is removed together with the undissolved residue from the cylinder by means of a screw conveyor at the base of the apparatus.—C. A. M.

Powdery or granular material; Process and apparatus for treating — in a shaking vessel. H. Stegmeyer. Ger. Pat. 305,237, Dec. 8, 1915. Addition to Ger. Pat. 303,475 (see page 427 A).

The shaking vessel contains a vertical partition extending nearly to the end of the chamber, which is also provided at one end with two pipes communicating with a deeper receiver. One of these pipes, which has a valve to prevent the liquid passing back, conducts the liquid from the shaking chamber, whilst the other conveys it back again. The whole apparatus or the shaking chamber only may be heated by means of a heating jacket or other device.—C. A. M.

Salt solutions or other liquids; Reflux condensing apparatus for cooling —. Maschinenfabrik Thyssen und Co., A.-G., Mülheim. Ger. Pat. 305,240, Dec. 29, 1916. Addition to Ger. Pat. 302,887 (this J., 1918, 360 A).

The distribution channels of a reflux cooling apparatus of the type described in the original patent are directly heated by the vapours within the apparatus. These vapours may receive their preliminary heating from a heating device below or near the distribution channels, or may be heated by the introduction of hot gases.—C. A. M.

Refrigerating machine; Rotary —. H. Lanz. Mannheim. Ger. Pat. 305,413, Apr. 2, 1915.

The machine consists of two horizontal cylindrical vessels on the same axis, the liquefier revolving in a vat of cooling water and the vaporiser in a vat of brine. The compressor is situated radially inside the liquefier, and the compressor pistons are reciprocated by an auxiliary shaft parallel to the axis of rotation and operated from the main shaft at double the speed by means of gear-wheels. The liquefier is charged with lubricant and a liquid refrigerating medium, e.g. liquefied sulphur dioxide, and the machine revolved. The casing of the compressor being freely suspended from bearings on the main shaft does not revolve; the pistons are operated by the auxiliary shaft and lubricated in a bath of oil. The liquefied gas is forced through an axial passage and regulating valve into the vaporising vessel and cools the surface of the latter, while gas is withdrawn by the pistons from the vaporising vessel through another axial passage and reliquefied in the compressor.—J. F. B.

Refrigeration; Process and apparatus for —. J. C. Bertsch, Edgewood Park, Pa. U.S. Pat. 1,235,037, May 7, 1918. Date of appl., Jan. 26, 1917.

The apparatus comprises an evaporator connected to a condenser, and a jet absorber receiving vapour from the evaporator and weak liquor at high pressure. A jet compressor receives the solution from the absorber and delivers it into a separator.

The weak liquor is cooled and returned from the separator to the absorber, and the gas passing from the separator to the condenser is compressed.—J. H. P.

Gas-compression plants for refrigerating and other purposes. A. Heane, Blayney, N.S.W. Eng. Pat. 111,081, May 4, 1917. (Appl. No. 6373 of 1917.) Under Int. Conv., Jan. 11, 1917.

Centrifugal drying machines. W. P. Thompson, London. From G. H. Elmore, Philadelphia, U.S.A. Eng. Pat. 115,909, May 26, 1917. (Appl. No. 7612 of 1917.)

SEE U.S. Pat. 1,235,193 of 1917; this J., 1917, 996.

Elevating or lifting acids or the like; Apparatus for —. T. Bradbear, Birmingham. U.S. Pat. 1,261,351, Apr. 2, 1918. Date of appl., June 18, 1917.

SEE Eng. Pat. 109,522 of 1916; this J., 1917, 1170.

Refrigeration; Process of —. E. A. W. Jefferies, Worcester, Mass., Assignor to Jefferies-Norton Corporation. U.S. Pat. 1,264,807, Apr. 30, 1918. Date of appl., Jan. 26, 1915.

SEE Eng. Pat. 106,675 of 1916; this J., 1917, 858.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coke breeze; Combustion of — on chain grates with forced draught. O. Wirmer. Z. Ver. deuts. Ing., 1917, 61, 818–824. Z. angew. Chem., 1918, 31, Ref., 134.

At the Badische Anilin und Soda Fabrik it has been found possible to admix 25% of coke breeze to the fuel burnt in chain grates without further modification. Above this proportion forced draught is necessary, the pressure being limited to that necessary to overcome the resistance of the fuel bed, thereby avoiding the passage of ash into the flues. Under such conditions coke breeze alone has been successfully used. The best results were obtained with a mixture of 80% of coke breeze with 20% of nut coal, when a boiler efficiency of 80% was attained. To secure the high temperature on the hearth required for the ignition of the breeze a long low furnace arch is necessary.—H. J. H.

Coke ovens; By-product — and town's gas supply. E. Rees, Wales and Monmouth Dist. Inst. of Gas Eng., May 29, 1918. Gas J., 1918, 142, 427–429.

The use of coke-oven gas for town supply where possible is advocated on national and local grounds.

By taking such supplies in bulk a local gas undertaking can meet increased demands with but small outlay of capital. Where the ovens are fitted with duplex mains it is preferable to take the richer portion of the coke-oven gas only. Otherwise it is advocated that the gas should be taken unstripped from a point just before the benzol scrubbers. The principal objection to coke-oven gas is the high nitrogen content, but, even with this, the newer requirements in respect of calorific value can be met.—H. J. H.

Effluents from ammonia-recovery plant of coke ovens. M. Marsson and R. Weldert. Mitt. Kgl. Landesanstalt f. Wasserhyg., 1917, 237—284. J. Gasbeleucht., 1918, 61, 200.

THERE are three effluents to consider, that from the stills, the liquid condensed from the gases leaving the saturator, and the effluent from the Claus sulphur-recovery kilns, of which the first is by far the most important. It amounts to 40 to 60 litres per ton of coal in direct processes and 200 to 450 litres per ton in indirect processes. In experiments on the disposal of still effluents from gas works made in Berlin during the period 1907—1910, it was found that the bulk of the suspended matter could be separated by settling for 1 hour and 97—99% after 24 hours. This left the dissolved matter unchanged. The yellow colour of the effluent darkened with time according to the intensity of the light and the alkalinity of the effluent. Treatment with flue gases was effective in precipitating dissolved lime. Attempts to remove other injurious constituents by chemical precipitants had no practical success. Filtration through lignite cinders produced an effluent which was non-poisonous to fish life. When applied to a road the effluent from stills had some beneficial effect in suppressing dust.

—H. J. H.

[Gas] purification; Notes on oxide —. H. Tindale. Gas J., 1918, 142, 554—555.

LABORATORY tests showed that the "oxides" available at Sydney, N.S.W., contain varying amounts of iron oxide in a form unsuitable for the purification of coal gas, since the reaction with hydrogen sulphide is slow, and the products of subsequent revivification include an appreciable amount of sulphur permanently combined with the oxide. Revivification is also slow, and, when effected *in situ*, requires an excess of oxygen—necessitating the admission of air, and consequently increasing the proportion of nitrogen in the gas. For efficient sulphiding of the oxide a temperature of not less than 80° F. (about 27° C.) is required; but, owing to the slow reaction, this temperature is not maintained by the heat of formation of iron sulphide, and in practice is supplemented by the heat of formation of ammonium salts. The latter reduce the purifying efficiency of the oxide and also cause excessive back pressure in the purifying system.

—W. E. F. P.

Gasoline; Determination of unsaturated hydrocarbons in —. E. W. Dean and H. H. Hill. U.S. Bureau of Mines, Tech. Paper 181. 22 pages.

THE proportion of unsaturated hydrocarbons in motor fuels appears not to affect the commercial value, but its determination is often useful as a means of determining the source and method of production of a given sample. Tests made by the authors show that the best methods are the determination of the iodine value, and absorption by strong sulphuric acid. Although the chemical mechanism of these two reactions is different, yet, in the case of cracked gasolines, the ratio of iodine value to percentage acid absorption lies between

fairly close limits. The average figure is 6.5, and most of the values fall between the limits of 6 and 7. The authors found the Hanus iodine method very satisfactory and accurate when the necessary precautions were observed. For such volatile liquids as gasoline it is necessary to deliver the sample below the surface of the chloroform or carbon tetrachloride by means of a capillary pipette. The sulphuric acid absorption method is rapid, reliable, and of fair accuracy, and is highly recommended as satisfactory for general use. The sample is run into a clean, dry, 6-inch Babcock cream bottle, cooled for a minute or two in ice-water, and then 200% by vol. of concentrated sulphuric acid is poured in, down the side of the bottle. This is then closed by a rubber stopper and the contents shaken, first slowly, then vigorously with a rotary motion for several minutes. Sulphuric acid is now added until the surface of the liquid is about level with the upper graduation mark, and the mixture allowed to stand overnight. A more speedy separation is obtained by revolving the stoppered bottle at once in a centrifuge for two or three minutes at a speed of 500 to 1000 r.p.m. Sufficient acid is then added to bring the level up to the lower graduation mark, and the contents are again centrifuged to complete the separation. More acid is added, and the residual volume of gasoline is read. The results have a possible error of 1 to 2%. Under the conditions of test, aromatic hydrocarbons are substantially unaffected. The "acid heat test" (determination of Maumené numbers) proved unreliable, especially for highly unsaturated mixtures. The bromine absorption method proved less satisfactory than the iodine method, although giving approximately equivalent results. There was more difficulty in obtaining concordant duplicate results, more time was required, and there appeared to be no compensating advantages.—T. St.

Emulsions; Water-in-[hydrocarbon] oil —. A. U. M. Schlaepfer. Chem. Soc. Trans., 1918, 113, 522—526.

PICKERING (this J., 1908, 88) showed that it is possible to prepare emulsions of hydrocarbon oils in water by means of precipitates which are insoluble in both liquids and are moistened more by water than by oil. To ascertain if solid particles which are more readily wetted by oils than by water would bring about the emulsification of water in oils, experiments were made with American carbon black (gas black, soot), thoroughly extracted with hot benzene, and such emulsions have been prepared. The emulsion obtained with 20 c.c. of water, 70 c.c. of kerosene, and 1 gm. of carbon was found to mix freely with kerosene but not with water. Under the microscope it was seen that the droplets of water were covered with a dark-brown skin of adsorbed particles of carbon; those particles which were not adsorbed formed aggregates in the kerosene phase. The emulsion was liquid and excess of kerosene separated after standing for one day, leaving a viscid emulsion which was stable. An emulsion made with 70 c.c. of water, 30 c.c. of kerosene, and 1 gm. of carbon also mixed freely with kerosene but not with water; this emulsion would not flow out of an inverted test-tube, and was stable for over a week. The order in which the ingredients are added makes no difference to the final result. The viscosity of these emulsions rises as the proportion of water is increased; when prepared by Pickering's method by alternately filling and emptying a garden syringe, the viscosity of the mixture rises as the number of strokes of the syringe, indicating the degree of mixing, is increased. In no case was it found possible to prepare an emulsion of oil in water by the use of carbon. "Carron oil," which

is prepared with lime water and linseed or rape oil, is another example of water-in-oil emulsions, whereas embrocations are of the oil-in-water type.

—J. F. B.

Artificial asphalts; Chemical composition of —, J. Marcusson. *Z. angew. Chem.*, 1918, 31, 113—115, 119—123.

THE most important artificial asphalts are composed of petroleum residues, lignite pitch, fat pitch, and coal tar and coal tar pitch, and these may be differentiated by the methods devised for natural asphalts (this J., 1916, 1099). *Petroleum residues*:—The residues from the distillation of petroleum with superheated steam resemble natural asphalts most closely both in composition and applicability. Whilst natural asphalts frequently show a relatively high proportion of mineral constituents (e.g. Trinidad asphalt, 33 to 55%), petroleum asphalts usually contain less than 1%. Free asphaltogenic acids are not present in petroleum asphalts, since they have been converted by the heat into anhydrides. For this reason the acid value of petroleum asphalts is low (e.g. less than 1 as against 2.8 to 15.4 for natural asphalts). Samples of petroleum asphalt of various origin contained from 2.7 to 3.4% of asphaltogenic anhydrides, whilst the saponification value was usually about 10, as compared with 29 to 36 in the case of natural asphalts. The proportion and character of the oily constituents depends upon the extent to which the distillation was carried, but even hard, friable petroleum residues invariably contain a considerable proportion of oil. For example, a hard sample of Californian origin contained 48%, whilst soft petroleum asphalts contained over 80% of oil. This oil resembles heavy cylinder oils in its composition and behaviour, has a similar iodine value (about

Petroleum asphalt from acid resins:—On diluting the sulphuric acid which has been used for refining petroleum products a resinous oily mass separates, which was first used as an asphalt substitute by Jenny (Ger. Pat. 3577; Dingler's Polyt. J., 233, 285). A sample of a product purified by washing and neutralisation with lime contained 15% of substances, mainly calcium compounds, insoluble in benzene. The soluble constituents, which resemble soft asphalt, had a saponification value of 18, and yielded 7% of solid black acids which were nearly insoluble in petroleum spirit. The unsaponifiable matter was 17.3%, asphaltic substances insoluble in petroleum spirit, 8.7%, and petroleum resins and oil, 52%. The oil in acid resin asphalts is of the type of machine oils, and is free from paraffin wax. These artificial asphalts are characterised by the presence of sulphonated addition compounds, which may be separated by treating the bitumen with petroleum spirit. The insoluble portion is not decomposed by boiling with potassium hydroxide solution, but when boiled with dilute hydrochloric acid is decomposed with liberation of the sulphuric acid. Acid asphalts are mainly used in the varnish industry; owing to their slight elasticity they are much less suited for building purposes. *Lignite tar pitch*:—The crude tar obtained in the dry distillation of lignite is not used directly in the asphalt industry. It contains relatively little asphaltic substances, and consists in the main of paraffin wax and oil, which must be separated by a second distillation. Frequently the distillation is carried only far enough to obtain the softer "goudron." Another lignite product consists of the acid resin pitch, and is obtained by distilling the acid resins formed during the purification of the oils and paraffin wax with sulphuric acid. Typical samples of these products had the following characters:—

	M. pt.	Acid value.	Saponif. value.	Insol. in hot benzene.	Saponifiable substances	Asphaltenes.	Resin melting below 100 C.	Oily substances.	
								%	Iodine value.
Lignite goudron ..	C 31	0.5	2.8	11.0	1.8	24.0	11.0	48.0	8.4
Acid resin pitch ...	88	4.4	13.4	20.0	6.0	36.0	8.1	26.0	26.1

18), and contains as a characteristic constituent a considerable amount of a high-melting paraffin wax, whereas the oil from natural asphalts contains only a small amount (usually less than 1%). The quantity of oil in natural asphalts is much less than in the case of petroleum asphalts, and after removal of resinous substances and unsaturated hydrocarbons by treatment with sulphuric acid, is fluid, whereas the oil from petroleum asphalts remains semi-solid after such treatment. The following table shows the comparative composition of typical natural and petroleum asphalts:—

The phenols of lignite tar pitch, unlike those of lignite tar oils, are partially insoluble in petroleum spirit, and this characteristic affords a means of distinguishing between lignite pitch asphalt and natural asphalt. *Fat-distillation residues*:—These are characterised by the presence of fatty compounds. They may contain variable proportions of free fatty acids, hydroxy-fatty acids, lactones, hydrocarbon compounds, asphaltic compounds, ketones, traces of neutral fat, sulphur compounds, and copper soaps. *Coal tar and coal tar pitch* are composed of insoluble carbonaceous substances (a

mixture of carbon with coal dust or coal-like resins) and of soluble tar bitumen, which contains, in addition to phenols, bases, and hydrocarbons, three distinct tar resins, respectively soluble in benzene, chloroform, and pyridine. These resins are aromatic compounds of high molecular weight. The resin soluble in benzene absorbs oxygen from the air, and is transformed into the other two resins. On this property mainly depend the drying power and resinification capacity of coal tar. (See also this J., 1911, 480; 1913, 646; 1914, 739.)—C. A. M.

PATENTS.

Firing-chamber for powdered fuel. W. D. Wood. New York, Assignor to Fuel Savings Co., Allentown, Pa. U.S. Pat. 1,266,088, May 14, 1918. Date of appl., Mar. 23, 1914.

THE fire-box of the furnace has a depressed auxiliary chamber the sides of which slope downwards and inwards to the bottom, the latter being inclined and having an opening at the lower end for removing slag and other accumulations. Overheating at the junction of the "mud ring" and side walls of the fire-box is prevented by means of an air space between the part in question and the refractory lining of the auxiliary chamber, a perforated plate being provided below the air space.

—W. E. F. F.

Coal; Apparatus for burning pulverised —. V. Z. Caracristi, Bronxville, and J. E. Muhlfield, Scarsdale, N.Y. U.S. Pat. 1,265,172, May 7, 1918. Date of appl., Sept. 1, 1916.

PULVERISED fuel is supplied tangentially to a horizontal cylindrical mixing chamber so as to pass through it in a helical path, and air for combustion is also supplied. The burning mixture emerging from the cylinder meets a rising column of air which has been supplied through a horizontal chamber below the mixing chamber, having its outlet end curved upwards in front of the mixing chamber so as to form a combustion chamber. Combustion is completed in this chamber by means of the additional supply of air.—W. F. F.

Gas; Manufacture of — in vertical retorts. H. J. Toogood, and R. Dempster and Sons, Ltd., Elland. Eng. Pat. 116,831, Oct. 27, 1917. (Appl. No. 15,662 of 1917.)

IN a vertical gas retort, in which steam is injected into the lower part, the steam is superheated by the surplus heat in the setting. Producer gas flues and waste gas or carbon dioxide flues are arranged vertically in the wall of the retort close to the vertical conduit in the wall through which the steam passes to the bottom of the retort. The steam is injected through a small pipe in the top of the conduit, and induces a flow of producer gas and waste gas through small valved pipes opening close to the steam outlet, and connected to the respective flues.—W. F. F.

Retorts, coke ovens, and the like; Construction of —. R. W. Easton, London. Eng. Pat. 116,873, Mar. 14, 1918. (Appl. No. 4525 of 1918.)

A HORIZONTAL retort, coke oven, or the like for the continuous distillation of coal, shale, peat, or other carbonaceous or nitrogenous substance, consists of a casing of metal, fireclay, or firebrick, or part metal and part fireclay or firebrick, built into a suitable furnace setting. Two or more intermeshing helical screws constructed as described in Eng. Pat. 109,663 are arranged within the casing and rotated by gearing at one or both ends. The material is fed from a hopper at one end and discharged from a hopper at the other end, and gases are drawn off from a pipe at the top at the middle of the retort. In a modification the screws are mounted in a second casing at the entrance to the retort, the casing and operating gearing being outside the furnace setting.

—W. F. F.

Water-gas; Apparatus for the production of —. Soc. d'Exploit. des Appareils Rateau, Paris. Eng. Pat. 112,942, Jan. 19, 1918. (Appl. No. 1114 of 1918.) Under Int. Conv., Jan. 24, 1917.

IN apparatus for producing water-gas, of the type in which the fuel in the generator is submitted alternately to blasts of air and steam, the air is injected by a fan operated by a steam turbine. The exhaust steam from the turbine passes to a steam accumulator so that it may be used for the steam blast when the turbine and fan are stopped. An auxiliary pipe for the direct supply of steam from the boiler may also be provided.—W. F. F.

Coal gas; Manufacture of —. Goodall, Clayton, and Co., Ltd., and T. Settle, Leeds. Eng. Pat. 115,997, Sept. 7, 1917. (Appl. No. 12,834 of 1917.)

A SERIES of vertical retorts is connected through valves at the bottom to a common highly heated horizontal passage, and through valves at the top to a common hydraulic main. When the fuel in the first retort is highly incandescent, superheated steam is admitted to the top and passes down through the retort to the passage below. The resulting water-gas passes upwards through the second retort which is at a distillation temperature, so that the distillation products are diluted and a large volume of gas of high calorific power is obtained. The process is then repeated with the second and third retorts and so on.—W. F. F.

Gaseous fuel; Process of manufacturing —. J. R. Rose, Edgeworth, Pa., U.S.A. Eng. Pat. 116,406, Aug. 3, 1917. (Appl. No. 11,238 of 1917.)

SEE U.S. Pat. 1,252,033 of 1918; this J. 1918, 144 A. Hydrogen may be added to the mixture of steam and fluid hydrocarbon, and the final mixture is subjected to a temperature not materially lower than 1600° F. (870° C.).

Hydrocarbon gas and method of producing the same. Hydrocarbon gas cartridge. L. Wolf, Assignor to The Thermalene Co., Chicago Heights, Ill. U.S. Pats. (A) 1,265,573 and (B) 1,265,574, May 7, 1918. Dates of appl., June 16 and Sept. 13, 1915.

(A) ACETYLENE is generated from a carbide and the heat evolved is used to gasify a hydrocarbon oil. The gases are mixed and then purified by cooling. (B) In the method described in (A) the gas is produced from a cartridge composed of a suitable carbide and a vehicle carrying the oil to be gasified.

—W. F. F.

Valves for controlling, reversing, and by-passing the flow of gas through purifiers, condensers, and the like. R. Dempster & Sons, Ltd., J. E. Horsfall, and H. Lumb, Elland. Eng. Pat. 115,936, June 21, 1917. (Appl. No. 8914 of 1917.)

VALVES are arranged in a casing outside each end of the purifier in such a manner that the flow of gas in the purifier may be from top to bottom, from bottom to top, from the middle to top and bottom respectively, or from both top and bottom to the middle.

Ammonia or its salts; Manufacture of — [by direct recovery process]. E. Oré, Caen, France. Eng. Pat. 115,449, Mar. 7, 1917. (Appl. No. 3399 of 1917.)

IN a process for direct, total recovery (as sulphate) of ammonia generated by carbonising coal, etc., the hot gas passes through a condensing column which is operated under such conditions that the whole of the free ammonia is carried forward by the gas. The condensed aqueous liquor containing ammonium salts is treated with lime in a column without the circuit traversed by the gaseous products of carbonisation, and the gaseous ammonia set free is returned to the condensing column and carried forward by the gas. After leaving the condensing column the gas passes through surface condensers and a tar separator, and thence into a saturator to recover the ammonia as sulphate.—W. E. F. P.

Tar from producer gases, such as brown coal producer gas; Process and plant for recovering — in two portions particularly suitable for dehydration. Berlin-Anhaltische Maschinenbau A.-G. Ger. Pat. 301,459, Apr. 4, 1915.

HOT producer gas is passed through a washer tar-extractor, followed by a spraying fan. The tar from the extractor is heated by a steam coil to about 70° C. until homogeneous, then the lower portion is allowed to cool slowly to 45°–50°, while the temperature of the upper portion is maintained at 70°, whereby the heavy tar is caused to sink, and the water to rise; on further cooling less than 5% of water remains in the tar. The tar from the spraying fans is similarly dehydrated, but being lighter than water, owing to the presence in it of small bubbles of gas, the tar rises to the top in the dehydrator. The gas may alternatively be expelled from the light tar by heating it under vacuum, whereby it is rendered heavier than water, and responds to treatment in the dehydrator in the same way as the tar from the extractor.

Petroleum hydrocarbons; Art of cracking —. J. S. Cosden and J. W. Coast, jun., Tulsa, Okla., Assignors to The Process Co. U.S. Pat. 1,261,215, Apr. 2, 1918. Date of appl., Dec. 26, 1916.

PETROLEUM hydrocarbons are cracked and vaporised and the vapours confined at a pressure greater than 50 lb. per sq. in. Natural gas, heated to a temperature higher than that of the confined vapours, is forced into the vapours, and a relatively cool high-boiling hydrocarbon liquid is forced into the mixture. The vapours are then led into a condenser to obtain a substitute for gasoline.—L. A. C.

Petroleum; Process for the distillation of —. C. E. Lepley, Bayonne, N.J. U.S. Pat. 1,261,410, Apr. 2, 1918. Date of appl., July 5, 1916.

PETROLEUM is distilled until gasoline and lighter products have been driven off and the temperature is then raised to approximately that of the boiling point of kerosene. A stream of highly heated

petroleum vapour is then injected under pressure into the delivery region of the still. When the lighter products formed at this stage have been driven off, the contents of the still are subjected to a temperature suitable for the distillation of kerosene or other heavy products.—L. A. C.

[Petroleum] distillation; Process of — and apparatus therefor. G. L. Prichard, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,254,335, Apr. 30, 1918. Date of appl., June 28, 1916.

A CONTINUOUS current of petroleum oil is passed through a series of stills, each still being provided with a vapour outlet and dephlegmating column. The oil, as it is fed into each still, passes down the corresponding dephlegmating column, meeting the ascending vapours. In each still are means whereby the oil is caused to flow in a tortuous passage.

—L. A. C.

Mineral oils; Apparatus for refining —. H. D. Lorch, Louisville, Assignor to Lorch Construction Co., Tulsa, Okla., and S. Z. Lorch, Louisville, Ky. U.S. Pat. 1,251,668, Apr. 30, 1918. Date of appl., Sept. 7, 1916. Renewed Nov. 24, 1917.

MINERAL oils are vaporised and the vapours led into a vapour separator comprising a casing having compartments for receiving respectively the heavier and lighter fractions. Each compartment has a separate outlet pipe, connected with a condenser, and means are provided by producing varying degrees of vacuum in the several outlet pipes, to cause separation of the vapours.—L. A. C.

Oils; Method of treating — [with liquid acids]. J. Bogaerts, Sutton, Surrey. Eng. Pat. 116,765, June 25, 1917. (Appl. No. 9099 of 1917.)

CRUDE and other oils are treated with liquid acids in a cylindrical metallic casing which is caused to rotate about a horizontal axis at right angles to the axis of the cylinder, the contents thereby being projected from one end to the other of the casing.

—L. A. C.

Bituminous binder and process for making the same. G. A. Henderson, St. Albans, W. Va. U.S. Pat. 1,264,932, May 7, 1918. Date of appl., Feb. 15, 1916.

THE bituminous residue of petroleum having an asphaltic base is mixed with sulphur and heated so that the sulphur is absorbed and the greater part of the oily constituent is driven off. The product contains 5–10% of sulphur.—W. F. F.

Coke ovens; Doors for —. R. Peel and T. F. Shevels, New Braucepeth Colliery, Durham. Eng. Pat. 116,393, July 18, 1917. (Appl. No. 10,368 of 1917.)

Coke oven doors. W. Cunningham, Moresby. Eng. Pat. 116,478, Feb. 23, 1918. (Appl. No. 3258 of 1918.)

PATENTS.

Shale [and coal]; Process for obtaining a distillate from — free from sulphur. G. E. Heyl, London. Eng. Pat. 115,867, Oct. 11, 1917. (Appl. No. 5081 of 1917.)

Two or more rotary drums are connected in series by a hollow shaft, each drum being surrounded by a hood into which hot gases are passed. The first drum is charged with shale or coal to which has been added 10 to 20% of coal-tar or other mineral oil in order that the distillation may be carried out at a lower temperature. A certain amount of scrap metal may also be added. The remaining drums contain scrap metal such as borings, turnings, and the like. The vapours generated in the first drum pass through a dust separator into the hollow shaft, and out through holes into the next drum in which they come in contact with the scrap metal which is heated to a temperature sufficiently high to promote the formation of metallic sulphides. Attrition of the metallic particles causes removal of the sulphide and exposure of fresh surfaces of metal. The vapours are removed from the apparatus by means of a vacuum pump, purified, and condensed.—L. A. C.

Pyroligneous acid; Method of distilling —. H. O. V. Bergström, Stockholm. U.S. Pat. 1,261,344, Apr. 2, 1918. Date of appl., June 19, 1917.

Woon spirit is separated from pyroligneous acid in a column apparatus and the acid passed through a column into a boiler, in which it is distilled under pressure. The vapours are led back through the column under pressure in an opposite direction to that of the acid, and then into an alkaline absorbent (lime). Unabsorbed vapours are led through the heating coil of a second boiler for pyroligneous acid, thus effecting a transfer of heat from the vapours to the acid.—L. A. C.

[Electric] lamp; Metallic-filament — and process of making it. H. J. Jaeger, Weehawken, N.J. U.S. Pat. 1,265,204, May 7, 1918. Date of appl., July 27, 1917.

A "CONCENTRATED" metallic filament is coated with a chloride of a metal of the chromium group (e.g. uranium), and the lamp is filled with an inert gas, exhausted, and sealed. The filament is then heated so that the chloride is decomposed and uranium deposited on the filament.—W. F. F.

Construction of retorts, coke ovens, and the like. Eng. Pat. 116,870. See IIa.

III.—TAR AND TAR PRODUCTS.

Chemical composition of artificial asphalts. Marcussou. See IIa.

PATENTS.

Naphthalene salts and similar substances; Apparatus for the extraction of — from the distillates of coal tar distillation. Brotherton & Co., Ltd., J. Porteous, and E. D. Whitelock, Leeds. Eng. Pat. 115,906, May 24, 1917. (Appl. No. 7485 of 1917.)

Each of a series of horizontal cylindrical vessels is provided with a steel inner tube in which is a rotating shaft fitted with a worm conveyor. The inner tubes are connected alternately at opposite ends of the apparatus by bends fitted with inspection doors; the outer vessels are similarly connected by vertical pipes. The tar oil is pumped into the top inner tube, passes down the series, and is cooled by ammonia or other refrigerant flowing through the annular spaces, preferably from the lower end. Naphthalene and other solids which separate are prevented from adhering to the walls of the tubes by the rotating worms, and are carried forward by the oil, being subsequently separated in presses. In the event of any cylinder being choked, it may be cut out by removing a connecting bend, the remaining sections being temporarily connected.—L. A. C.

Phthalic anhydride; Making —. T. D. Greenley, Glen Ridge, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,261,022, Apr. 2, 1918. Date of appl., Mar. 13, 1917.

NAPHTHALENE is heated with an insufficient quantity of fuming sulphuric acid to 250° C. in the presence of a catalyst, e.g., mercury sulphate. Two additional quantities of fuming sulphuric acid are added, the temperature being again raised to 250° C. after each addition, and then finally to 300° C. to expel the phthalic anhydride from the reaction mass.—L. A. C.

Process and plant for recovering tar from producer gases, such as brown coal producer gases, in two portions, particularly suitable for dehydration. Ger. Pat. 301,459. See IIa.

Manufacture of resins. U.S. Pat. 1,263,813. See XIII.

IV.—COLOURING MATTERS AND DYES.

Dyes derived from sulphazone. A contribution to Claasz's new theory of the indigo chromophore. W. Herzog. Ber., 1918, 51, 516—521.

SULPHAZONE condenses with α -isatinanilide and thionaphthenequinone-anilide to form vat dyes of the indigoid type, without, however, any great affinity for fibres. These do not contain the usually-accepted indigo chromophore -CO-C=C-CO- , but their tinctorial properties can be ascribed to the presence in them of Claasz's indigo chromophores (this J., 1916, 1150). The dyes are represented therefore by the formulæ,

Condensation with β -isatinanilide yields a compound which is devoid of tinctorial properties, being related to the above as indirubin is to indigotin. (See further J. Chem. Soc., 1918, 1, 310.) —J. C. W.

Anthocyanins and anthocyanidins; Production of —. III. A. E. Everest. Proc. Roy. Soc., 1918, B 90, 251—265. (See also this J., 1914, 1199.)

From the petals of a purple-black viola the author has isolated an anthocyan pigment, which he has shown to be a delphinidin glucoside, identical with the violanin obtained by Willstätter and Weil from the blue-black pansy (see this J., 1916, 1213). The yellow sap-pigment from the same viola petals contains a myricetin glucoside and another yellow sap-pigment which does not give a green coloration with dilute alkalis. The so-called alum reaction described by Willstätter and his collaborators is shown to be due to the presence of iron as an impurity in the alum, no colour being obtained with the pure reagent.—W. G.

Sorghum; Utilisation of the red dye obtained from the leaf sheaths and stalks of certain species of —. G. C. Dudgeon. Agric. J. of Egypt, 1917, 7, 150—153. Bull. Agric. Intell., 1918, 9, 506.

The red pigment developed at maturity in parts of the leaves and stems of certain varieties of sorghum (e.g., *S. technicum*) is used in Africa for dyeing goat leather and staining grasses used in basket making. The red pigmentation has been observed in varieties of broom sorghum, and even in *S. vulgare* in the form of red spots. The origin of the colouring matter is still unknown; it contains two pigments: one brick-red to orange-red in shade which is extracted by boiling water, the other crimson or purplish-red, extracted by boiling the residue with sodium bicarbonate. An infusion of the pigment in water containing a little sodium carbonate dyes tanned leather to shades ranging from red to brown, and unprepared wool brown. Wool previously boiled with alum is dyed by an infusion in

pure water to shades of rose and orange-pink, but the colour fades on exposure. In the case of unprepared wool, after-treatment with sodium "hyposulphide" fixes the dye. The addition of sodium "hyposulphide" to the water in which the sorghum is boiling gives a browner shade which appears to be fast to light. With zinc nitrate and tartaric acid as fixing agents, very bright dark orange to rose-pink shades are produced on silk and are apparently fast. The collection of the pigment does not interfere with the ordinary utilisation of the sorghum.—J. F. B.

Adsorption compounds [of dyes]. Haller. See VI.

PATENTS.

Sulphur dyestuffs; Process for manufacture of yellow —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 302,792, Aug. 22, 1916. Addition to Ger. Pats. 292,148, 293,187, and 293,558 (this J., 1916, 832, 922, 1056).

INSTEAD of the simple diamines of the diphenyl series methylated in the nucleus, or their previously specified derivatives, the intermediate products of a primuline nature obtained by melting the specified diamino-compounds with *o*-, *m*-, or *p*-toluidine, in equimolecular proportions, and sulphur, or else mixtures of the methylated diamines or their derivatives and toluidine are melted with benzidine and sulphur at high temperatures.—J. F. B.

Colouring matter soluble in ammonia and water; Process for the manufacture of a —. O. Bauer. Heilbronn. Ger. Pat. 303,599, Apr. 25, 1917.

A COLOURING matter particularly suitable for wood staining is prepared by dissolving tanned leather waste in a boiling aqueous solution of a caustic agent. This colouring matter possesses the advantage of not roughening the pores; a large variety of shades is obtainable by the addition of more or less ammonia or water.—J. F. B.

Gallocyanine dyestuffs with amines; Manufacture of condensation products of —. O. Imray. London. From Soc. Chem. Industry in Basle, Switzerland. Eng. Pat. 116,754, June 19, 1917. (Appl. No. 8802 of 1917.)

IN the condensation of two mols. of a gallocyanine dyestuff with an aromatic amine, one mol. of the gallocyanine is converted into arylaminogallocyanine whilst the other is reduced to its leuco-compound, which escapes condensation. This reduction is prevented by conducting the reaction in presence of hydrogen peroxide or a derivative thereof, such as a persulphate or perborate, and completing the condensation by heating for several hours on the water-bath; a suitable diluent, such as alcohol, may be used. Condensation products may be made with aromatic amines or with amines containing, besides the free amino group, an acylamino group or an imino-azole residue. The condensation products may be converted into leuco-compounds by dissolving in formic acid and reducing with zinc dust, or by other known methods, and then applied in the same manner as chrome-printing dyestuffs. —J. F. B.

Ligninsulphonic acid or its salts; Method of preparing azo colouring matters from —. E. Oman. Stockholm. Eng. Pat. 103,479, Jan. 4, 1917. (Appl. No. 183 of 1917.) Under Int. Conv., Jan. 14, 1916.

LIGNINSULPHONIC acid or one of its salts (see this J., 1918, 121 A) is coupled with a diazotised aromatic

amine, and the azo dyestuff produced is precipitated either directly or after the addition of salt. *Example*: 6 grms. of aniline diazotised in the ordinary way is added while stirring to a solution of 5 grms. of sodium ligninsulphonate of 60% purity in 50 grms. of water; a brick-red colouring matter is precipitated. Brown and red colouring matters are obtained with benzidine and β -naphthylamine-disulphonic acid respectively. If preferred, the crude waste sulphite lye may be used instead of the sodium ligninsulphonate, but the colouring matters are then contaminated with impurities.—J. F. B.

[*Anthracene*] *vat dycstaffs and process for their formation*. M. Hjinsky, Assignor to R. Wedekind und Co., Uerdingen, Germany. U.S. Pat. 1,261,354, Apr. 2, 1918. Date of appl., Sept. 15, 1913.

SEE Eng. Pat. 19,435 of 1913; this J., 1914, 415.

Chromium compounds of azo dyes. R. Bohn, Mannheim, and P. Nawiasky, Assignors to Badische Anilin u. Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,264,604, Apr. 30, 1918. Date of appl., July 10, 1913.

SEE Eng. Pat. 26,460 of 1912; this J., 1913, 905.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; The testing of — by steaming. M. Freiburger. *Färber-Zeit.*, 1917, 28, 221—224, 235—236, 249—252. *Z. angew. Chem.*, 1918, 31, Ref., 146.

CUTTINGS of cotton cloth were treated with solutions of various alkaline salts, dried, and steamed, then compared with a scale of standard whites prepared by staining a good white cloth with known quantities of diluted scouring liquor. Fats play no appreciable part in the yellowing of the goods during steaming. Treatment with sodium ricinoleate causes a slight lowering of the colour. As regards the behaviour of the "gums," both dry heating and steaming cause a yellowing of cotton at all stages of the scouring and bleaching process, the discoloration due to steaming increasing with the time. The presence of alkali intensifies the yellowing. Fully scoured cotton is discoloured only slightly less than the raw goods; in this respect the non-cellulose impurities differ but little from the cellulose. Chemicked goods show the strongest discoloration, those bleached cold show it more strongly than those bleached warm and acid; goods bleached warm with an excess of soda in sodium hypochlorite are relatively less subject to yellowing. Mercerised goods keep their colour well in spite of their greater attraction for water. Oxycellulose becomes quite brown on steaming, about 100 times darker than cellulose; hydrocellulose is ultimately discoloured less than cellulose. By steaming cotton treated with sodium ricinoleate comparatively with the untreated sample and observing its discoloration, a relative measure of the proportion of oxycellulose present is obtained. The main cause of the yellowing of cotton is the presence of β -oxycellulose.—J. F. B.

Paper yarns and textiles; Effect of cold on —. M. Lummerzheim. *Monatsschr. Textil-Ind.*, 1917, 32, 144. *Z. angew. Chem.*, 1918, 31, Ref., 147.

PAPER yarn comes on the market with a very high percentage of moisture, often with 40—80 parts of moisture per 100 of dry weight. In cold weather the moisture freezes and destroys the cohesion of

the individual fibres so that the yarn or fabric loses its strength and elasticity. Total destruction may take place if the yarn is suddenly subjected to intense cold. It is better, therefore, to retain the heat which is liberated when a portion of the water in the yarn freezes, so that it may moderate the rate of cooling. Yarns packed in closed boxes and transported in covered wagons are less liable to injury by frost than when they are packed in crates or sacks and are exposed to draughts. When paper yarn shows the presence of ice, it should not be worked up in the frozen state but should first be slowly thawed. In frosty weather the weaving room should not be allowed to get cold; warps which have become stiff cannot be stretched tightly and uniformly without many breaking.—J. F. B.

Soda wood pulp by Ungerer's process; Manufacture of — on the large scale. C. Ziegelmeyer. *Papier-Zeit.*, 1918, 42, 1855—1856. *Z. angew. Chem.*, 1918, 31, Ref., 174—175.

IN Ungerer's process the digestion of wood by the soda or sulphate process is carried out fractionally on the counter-current principle. The digestion liquor passes from boiler to boiler in a battery in such a way that the nearly spent lye comes into contact with the freshly charged wood and the fresh lye is fed on to a partly digested charge, exerting its maximum solvent action on the difficultly soluble incrusting and colouring matters. The process gives an exceptionally light coloured pulp. The washing waters are not mixed with the black liquors but are used for preparing fresh liquor, so that the spent lye is not diluted before evaporation and there are no effluents. The plate evaporator designed by the author gives a 24—30 fold evaporation. The pulp mill at Stuppach is producing 5—5½ tons of pulp daily by this process, and considerable extensions are contemplated. The Ungerer process is capable of producing excellent pulp from coarse-grained wood; the pulp can be fully bleached with 1—2% of bleaching powder, and owing to its low ash it is very suitable as a substitute for cotton for munition purposes.—J. F. B.

Soda and sulphite pulps; Differentiation of —. P. Klenm. *Woch. Papierfabr.*, 1918, 48, 2159—2161. *Z. angew. Chem.*, 1918, 31, Ref., 175.

IN the sulphite process certain residues of the wood substance survive and are found in the paper, whereas by the alkaline process the purification is far more complete. These residues of cell-contents, which are particularly to be found in the cells of the medullary rays, may be made visible by staining and serve for the differentiation of soda and sulphite pulps. The residues are found even in bleached sulphite pulps and exist as aggregates or chains of small spherical elements. Their staining capacity depends on the presence of resin; with an aqueous-alcoholic solution of Sudan III, with a little glycerin, they are stained red; with zinc chloride-iodine, sulphur-yellow. In preparing the pulp for microscopic examination care must be taken to avoid dissolving the resin by the caustic soda. Medullary ray cells are so numerous that the presence of even 5—10% of sulphite pulp in a mixture can thus be detected. For quantitative estimation of mixtures of sulphite and soda pulps, a solution of rosaniline sulphate with a little alcohol and sulphuric acid is of service; the contents of the pitted pores are strongly stained in the case of sulphite pulps but not with soda pulps. The inner side of the fibre wall of sulphite pulp is more strongly dyed than the outer. In zinc chloride-iodine, the sulphite fibres show a characteristic venation.—J. F. B.

Sulphite waste liquors; Concentration of —. E. Oman. *Papierfab.*, 1918, 15, 605–607. *Z. angew. Chem.*, 1918, 31, Ref., 176.

ONLY about 16% of the solid constituents of the sulphite waste liquors can be utilised by fermentation. The waste liquors, after distillation of the spirit, may be evaporated and used as a binder for sand moulds in iron foundries. In place of evaporation, which is expensive, the author suggests concentration by freezing, which may take place either before or after the fermentation. Sulphite liquor freezes at 0.5° C., and the sugar is not injuriously affected, as it is during evaporation. By use of a centrifugal the ice crystals are easily removed, and with repeated freezing it is possible to obtain a liquor with 35% of dry substance. The cost of evaporating 1 ton of water is ten times as great as that of freezing out 1 ton of ice when water power is used for the refrigerators.—J. F. B.

Cork slabs from cork waste. H. Ost. *Z. angew. Chem.*, 1918, 31, 105–108.

SLABS of considerable strength may be made by compressing ground cork waste and heating it at 160°–180° C. while under compression. No binding agent is required, and it has been suggested that the natural resin of the cork serves as a binder. Various samples of ground cork were extracted several times for 24 hours with alcohol and with chloroform in the cold. The maximum amount of the united extracts, in the case of cork dust, was 9.35% of the air-dry weight. Higher results were obtained when water was also used, *e.g.*, up to 10.3%, since the tannins are also extracted, but water has an injurious action on the cork substance. The extract was resinous and began to melt at 150° C. Equivalent weights of comparative samples of natural and extracted granulated cork were compressed to form plates of various thickness, then heated in the moulds for about 3 hours at 180° C. or for 15–20 hours at 160° C. At the higher temperature a slight browning of the cork substance was observed, but at 160° C., in spite of the longer time, there was no perceptible decomposition. Tensile tests were made in a cement-testing machine; the strength depended on the degree of compression and the heating. The more favourable results with plates compressed under 7 atmos. varied from 6 to 8 kilos. per sq. cm.; some very heavily compressed plates showed 14 kilos. per sq. cm. The plates from the extracted cork were only slightly inferior to those from the natural cork. The resistance to water and steaming was almost entirely a function of the temperature of heating while under compression; plates heated at 50°–100° C. readily disintegrated, while those heated at 180° C. were the most resistant. Heating before compression was useless. The compressed plates adhered firmly to the walls of the mould, but pieces of tissue paper placed between prevented this adhesion and showed no oily or resinous stain. The author concludes that resinous extractive matters play no part in binding the compressed plates, but that their solidity depends on an interlocking or felting of the cork cells. Without heating, the elasticity of the cork is restored by steaming and the plates fall to pieces, but at 160°–180° C. incipient decomposition destroys the elasticity and the felting of the cells is permanent and rigid.

Recovery of grease from waste materials by the solvent extraction process. Garner and Carmichael. See XII.

Carbohydrates other than sugar [e.g., waste liquors from cellulose manufacture] which are suitable as yeast foods. Bokorny. See XVIII.

PATENTS.

Woollen goods; Process for protecting — from moths. E. Naefe, Berlin-Britz. Ger. Pat. 304,503, Feb. 27, 1917.

The fabric is impregnated with soluble salts of aignic acid and then treated in a bath of antimony salts for about 30 minutes.—J. F. B.

Wool; Method of cleaning, carbonising, and sterilising raw —. H. Hey, Dewsbury. Eng. Pat. 116,763, June 23, 1917 (Appl. No. 9034 of 1917.)

UNSCOURED raw wool is steeped for 1½ hours in a bath containing 4.5% of sulphuric acid and 1% of 40% formaldehyde; the wool is removed and hydro-extracted and then dried at about 80° C. until the vegetable matter becomes friable. The dried wool is treated twice with a volatile solvent in a centrifugal degreasing machine, being centrifuged after each treatment. The adhering solvent is evaporated, the wool is passed between fluted rollers, and the pulverised impurities are removed by opening and beating the wool in a current of air.

—J. F. B.

Boiler for treating substances, particularly cellulose, suspended in liquids, with steam. F. Böck, Vienna. Ger. Pat. 302,893, Nov. 5, 1915. Under Int. Conv., Oct. 25, 1915.

THE boiler is provided with a tubular vertical extension open at the top to increase the pressure of liquid in the body of the vessel. A mechanical circulating device is situated in a pipe open at both ends through which liquid is pumped from near the bottom of the boiler and delivered at a higher level. Pipes are arranged to deliver live steam and fresh water or liquor near the bottom of the vessel, and a conical gas or vapour collector formed of a series of overlapping plates is suspended in the upper part of the boiling vessel and communicates with a relief pipe which extends up the tubular extension and terminates above the level of the liquid therein. The pipe through which the fresh water or liquor is introduced is coiled around the upper surface of the conical vapour collector. The apparatus is suitable for the continuous or intermittent washing of cellulose or nitrocellulose while boiling.—J. F. B.

Paper; Process for utilising waste — for re-making into white paper. J. Galloway and A. Stratton, Portobello. Eng. Pat. 115,940, June 23, 1917. (Appl. No. 9045 of 1917.)

WASTE paper is boiled with 60–80% caustic soda under a steam pressure of 35–40 lb. per sq. in., washed in the boiler with warm water, then broken and washed in breaking engines; the pulp is passed over sand tables and through strainers, the excess of water is removed by drum washers, and the concentrated pulp bleached and treated for the manufacture of paper.—J. F. B.

Plants for papermaking; Treatment of certain —. C. J. Stewart, London, H. D. Hall, Croydon, and H. Beadle, Sidcup, Exors. of C. Beadle. Eng. Pat. 116,005, Sept. 22, 1917. (Appl. No. 13,679 of 1917.)

CERTAIN fibrous materials such as many freshly cut green crop plants, not highly lignified, particularly *Hedychium coronarium* and cotton seed hull fibre, are reduced to pulp for papermaking by treatment in the beating engine with a hot alkaline liquor below the boiling point. In the case of fresh *Hedychium*, 6% of its weight of caustic soda may be used at 80° C. and the process may last for 2–4 hours; in many cases the alkali is neutralised

by the organic matters extracted from the fibre but if an excess is employed it may be removed by neutralisation or washing. If desired, the juices of the plants may be removed before the alkaline treatment. Material may be crushed and steeped in an alkaline liquid, stored and transported, and subsequently treated with hot alkali in the beating engine.—J. F. B.

Paper-filler; Liquid — and process of making the same. W. N. Kohlins, Newark, N.J. U.S. Pat. 1,261,335, Apr. 2, 1918. Date of appl., July 18, 1917.

"SATIN WHITE" is liquefied by mixing with it less than 3% of gum arabic, dextrin, and "saccharin," and the fluid mixture is used as a paper-filler.
—J. F. B.

Paper for textile purposes; Manufacture of —. G. und H. Bencke Ges., Lübau. Ger. Pat. 304,772, Sept. 29, 1916.

THE paper pulp or the finished paper is treated with a very dilute solution of a colour-lake ("Farb-lack") in benzine, which increases its resistance to water and acids.—J. F. B.

Paper textiles; Process for cleaning old —. T. Goldschmidt A.-G., Essen. Ger. Pat. 305,427, Sept. 11, 1917.

THE textiles are freed from large impurities by mechanical treatment and are then subjected consecutively to treatments with water and bleaching powder or chlorine solution, and finally to a mechanical finishing operation, e.g. in drying machines, presses, or calenders. The treatment in the various baths should not be so prolonged as to loosen the texture of the fabric to such an extent that it cannot be restored in the finishing.—J. F. B.

Waste paper; Process for decolorising —. W. Abele, Berlin-Wilmersdorf. Ger. Pat. 305,343, May 8, 1917.

THE liquid used for removing ink, etc., from the waste paper is circulated continuously through a vessel containing the paper and through a heater.

Cellulosic materials and products thereof; Process of treating the residual liquor obtained in the hydrolysis of —. T. B. Wagner, Brooklyn, N.Y. U.S. Pat. 1,261,328, Apr. 2, 1918. Date of appl., Sept. 17, 1917.

THE fermented sugar-containing liquor resulting from the hydrolysis of cellulosic material is concentrated, after the distillation of the alcohol, the concentrated product containing more than 30% of reducing sugars (calculated as dextrose) and approximately 25–35% of water.—J. F. B.

Paper pulp and other fibrous materials; Apparatus for beating —. Apparatus for treatment of paper pulp and other fibrous materials. C. M. Cowan and J. Brown, Musselburgh. Eng. Pats. 115,972 and 116,040, July 31, 1917. (Appl. Nos. 10,999 and 18,952 of 1917.)

Straining pulp and the like. J. Paramor, Rickmansworth, Assignor to the Watford Engineering Works, Ltd., Watford, and J. M. Henry, Newbury. U.S. Pat. 1,261,054, Apr. 2, 1918. Date of appl., Dec. 12, 1916.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Silk; Bleaching of raw — by permanganate. E. Ristenpart. Färber-Zeit., 1918, 29, 37–38.

THE *aqua-regia* bleach is entirely obsolete and uncertain in its action; the nitrite bleach is safer and less costly but it always leaves a yellow with a greenish or brownish tone, according to the duration of treatment. The permanganate bleach is cheaper than the peroxide process. Raw silk is wetted out hot with "Monopol" soap, rinsed, and treated for half an hour at the ordinary temperature with 90 times its weight of a 0.1% solution of potassium permanganate. In presence of 0.1% of sodium hydroxide the action of the bleaching bath is very deleterious; the silk loses about 6% in weight and the tensile strength and stretch are seriously lowered. The neutral permanganate bath also removes about 6% in weight, but the strength is unaffected and the stretch is lowered to a less extent than with the alkaline solution. In neutral permanganate there is a liberation of alkali as the result of the reaction, and the best results are obtained in presence of 0.1% of sulphuric acid, with a loss of weight of 0.5%. The hanks are cleared with a solution of 3 grms. of bisulphite and 1.5 c.c. of sulphuric acid per litre. The colour obtained is not, however, a real white but is considerably better than with the older processes. When the permanganate bleach in presence of acid was repeated three times in succession, instead of an improvement in colour, the reverse was obtained, the colour falling off to a brownish shade, with increasing loss of weight and tensile properties. Treatment with 0.1% "blankit" solution at 40°–60°C. after the removal of the manganese with bisulphite removed the red tinge from the bleached "white" but left the yellow more prominent.
—J. F. B.

Dyeing; Theories of —. The theory of the acid dyebath for wool. M. Fort. J. Soc. Dyers and Col., 1918, 34, 124–126.

REFERRING to the experiments by Harrison (this J., 1918, 238 A), who showed that sulphuric acid could be entirely removed by washing wool with distilled water, the author states that this differs from his own experience. There is a large amount of evidence relating to the equilibrium in dyeing and stripping and the chemical properties of fibre and dyestuff to be dealt with before the chemical theory of dyeing, in the main aspect of the process, can be dismissed as inadequate. The value of a theory must be measured by its practical results and the theory of the acid-wool compound which the author has supported is more fruitful in technical application than theories based on remote and little understood electrical phenomena. Protein substances of the most diverse origin and physical structure all

behave very similarly in the acid dyebath and their chemical relationships are far more obvious than any other properties on which a theory of dyeing could be based. Moreover, analogies which have been drawn in support of the author's views, such as the mechanism of the dyeing of cotton impregnated with benzidine (this J., 1916, 304) and the reaction between magnesium oxide and Crystal Scarlet, are too strong to admit of any other than a chemical explanation. Lastly Harrison's experiments do not explain the decomposition of neutral salts by wool in order to attain combination with sulphuric acid.—J. F. B.

Adsorption compounds [of dyes]. R. Haller. *Kolloid-Zeits.*, 1918, 22, 113—133.

THE so-called adsorption compounds formed by dyes with other substances behave as mechanical mixtures rather than as chemical compounds. The mode of segregation of the adsorbed substance varies with the structure and physical properties of the adsorbent. The adsorption of a given dye by a crystalline substance, such as barium sulphate, is apparently very different from the adsorption which occurs with a colloidal substance, such as cotton wool, but the differences are probably entirely due to the difference in the physical characteristics of the two adsorbents. The adsorption effect is also appreciably different, so far as microscopic observations go, if the adsorbent is employed on the one hand in sol form and on the other in the form of a coarse powder. When the adsorption compounds are treated with chemically indifferent solvents, the effects observed are those which would be expected on the assumption that the "compounds" are mechanical mixtures. The absorption spectra of the solutions which are obtained by dissolving the adsorption compounds in suitable solvents are also readily accounted for on the mixture hypothesis. The adsorption compounds which are formed by easily fusible adsorbents, such as stearic and palmitic acids, melt at temperatures which are near to the melting points of the pure adsorbents. The general physical properties of the adsorption compounds are therefore such as may be readily interpreted on the assumption that these are mechanical mixtures of the adsorbent and adsorbed substance. The action of mordants, on the other hand, is probably due to the formation of chemical compounds between the mordant and the dye, and these compounds subsequently form adsorption compounds or intimate mechanical mixtures with the fibre in the process of dyeing.—H. M. D.

Black dyeing on iron mordant. O. Diehl. *Färber-Zeit.*, 1917, 28, 233. *Z. angew. Chem.*, 1918, 31, Ref., 136.

A BLACK, which possesses the advantage of satisfying all requirements as regards fastness and not injuring the wearing qualities of the most delicate fabrics, is produced by dyeing a mixture of alizarin and dinitroresorcinol on an iron mordant.—J. F. B.

Naphthylamine Claret; Dyeing to the shade of —. O. Diehl. *Färber-Zeit.*, 1917, 28, 212—213. *Z. angew. Chem.*, 1918, 31, Ref., 136.

OBJECTIONS to the use of Naphthylamine Claret, on account of the easily decomposable printing colour and injury to the white of goods prepared with β -naphthol, led to experiments to obtain the same shade by dyeing with alizarin and Alizarin Cyanin on an alumina mordant. The brightness and fastness to light and washing were perfectly satisfactory. The procedure adopted is as follows:—The material is either printed with thickened aluminium acetate or padded with unthickened aluminium

acetate on the hot flue and the white discharged with citric acid. After the usual passage through the preliminary steamer the goods are degummed and dyed in a mixture of Alizarin, bluish, and about "1/2 N" Alizarin Cyanin R, oiled, steamed, and soaped.—J. F. B.

Textiles; Action of laundry agents on —. A. Grün and J. Jungmann. *Seifenfab.*, 1917, 37, 507—510, 529—531, 553—555, 579—581, 603—606. *Z. angew. Chem.*, 1918, 31, Ref., 146.

AFTER 30 washings with hard soap, soda, sodium silicate and perborate, respectively, linen and cotton textiles showed higher strength values with hard water than with soft water. With soft water sodium silicate showed a distinct injurious action on cotton, and perborate was still more harmful. Goods washed with soap improve in lustre and show a brilliant white colour by reflected light; goods washed in soda show a strong yellowing in transmitted light with a slight shade of pink; by reflected light they appear slightly grey. After washing with silicate the goods are white but quite without lustre, being dull and chalky. The handle of goods washed with soda or silicate is very poor. The loss of tensile strength suffered by textiles in washing is not a simple measure of the changes which have taken place in the fibres. In estimating the loss of quality the external appearance of the fabric must be taken into account and particularly the splitting of the fibres as observed microscopically. Perborate in presence of soap is decomposed with equal rapidity in distilled and in tap water. Soda slightly retards the decomposition; silicate makes a solution of perborate in hard water practically stable and has some influence in the same direction in cold distilled water. The alkalinity of perborate solutions is of little importance compared with the rapidity with which they part with their oxygen.—J. F. B.

Utilisation of the red dye obtained from the leaf-sheaths and stalks of certain varieties of sorghum. Dudgeon. See IV.

PATENTS.

Bleaching and washing baths; Process for recovery of oxalates and pyrophosphates from exhausted —. O. Reich, Lindenberg. Ger. Pat. 304,601, Mar. 17, 1917. Addition to Ger. Pat. 300,523.

THE bleaching baths are diluted until pale in colour, treated with ammonium salts, and the pyrophosphoric acid is precipitated by manganese or magnesium salts; the oxalic acid is precipitated from the filtrate by the addition of alkaline-earth compounds.—J. F. B.

Bleaching apparatus. F. Donahue, Utica, N.Y. U.S. Pat. 1,263,045, Apr. 16, 1918. Date of appl., Apr. 30, 1917.

A CLOSED kier is provided with a perforated false bottom and with a vertical circulating pipe passing through the false bottom to the upper part of the kier. Steam is supplied below the false bottom through a steam jet tube extending up into the circulating pipe. In addition to this, an external circulating pump is provided which can be arranged to draw liquid either directly from the kier below the false bottom or from either of two cisterns which are adapted to receive liquid discharged from the bottom of the kier, such liquid being delivered by the pump into the upper part of the kier.

—J. F. B.

Dyeing machines, washing off machines, and the like. J. Farrar, Halifax, and A. R. Whitehead, Leeds. Eng. Pat. 115,982. (Appl. Nos. 5785, Apr. 25, and 9502, July 3, 1917.)

THE dyeing vat is constructed with a false bottom composed of boards spaced apart and has a circulating chamber at one end separated from the vat by a division board. The dye or other liquor is circulated from the circulating chamber, passing up between the boards of the false bottom into the vat and back over the dividing board into the circulating chamber. When used for washing off, fresh water enters the dyeing vat at the end remote from the circulating chamber, through apertures in a transverse pipe arranged to assist the circulation of water through the vat, and the water overflows and escapes at the circulating chamber, or at or near the division board, through a trough from which the upper layer, with the floating impurities, is discharged. The lid of the vat, from which the hank frame is suspended, is provided with sprays from which water can be sprayed on to the heads of the hanks after removal of the liquor.—J. F. B.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,261,498 and (B) 1,261,499, Apr. 2, 1918. Dates of appl., (A) Feb. 15, (B) Jan. 31, 1917. (See also this J., 1918, 265 A.)

(A) THE receptacle contains a series of removable fibre chambers adjacent to each other, each chamber having a non-perforated side and a foraminous bottom fitted with a number of vertical spindles; a second chamber below the fibre chamber contains a series of vertical rods, and a third chamber, also containing rods, is situated above the fibre chamber. A small testing device similar to the main device but without the third upper chamber is connected with the large one below the foraminous bottoms and means are provided for forcing liquid through the two systems simultaneously. (B) The foraminous plates below and above the fibre chamber are composed of series of converging and diverging elements with openings between the elements; means are provided for adjusting and maintaining the upper plate at varying distances from the lower one. A liquid supply chamber is situated below the fibre chamber formed between the two plates, and a chamber below the liquid supply chamber contains a series of nested members converging downwards, so arranged as to allow the passage of a liquid between them. A smaller testing device is provided and also means for conducting air and circulating liquid through the two devices equally.

—J. F. B.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,261,500 and (B) 1,261,501, Apr. 2, 1918. Dates of appl., (A) Apr. 28, and (B) May 16, 1917. (See also this J., 1918, 297 A.)

(A) THE foraminous cylinder on which the fabric is rolled is provided with annular members capable of sliding inwards thereon and other annular members sliding over the first, the inner faces of all of them forming a surface capable of abutment upon the edges of the rolled-up fabric. A second foraminous cylinder is spaced inside the first and is revolvable therewith; a series of tubes connects the entire inner face of the second cylinder with a source of liquid supply and the liquid passes into the space between the two cylinders and thence through the first cylinder during the rotation; steam is also introduced between the two cylinders and the adjustable members to prevent the passage of the liquid through any portion of the first cylinder which is not covered by the fabric. (B) The receptacle contains a reel with non-perforated sides, an inner foraminous cylinder integral with the sides of the reel with longitudinal openings, an outer

foraminous cylinder having a series of members extended outwards and inwards with openings in the sides thereof, an adjustable foraminous belt to enclose the fabric and carrying members extended inwards, a series of tubes covering the inner face of the inner foraminous cylinder, means for continuously passing liquid through the system and for passing air through the tubes during the revolution of the reel.—J. F. B.

Silk-dyeing. S. Saxe, New York. U.S. Pat. 1,263,126, Apr. 16, 1918. Date of appl., Aug. 16, 1917.

SILK is dyed and weighted by treatment with a strong extract of wood of Osage orange, or in dyeing black, the silk is mordanted and dyed, then worked in a strong extract of Osage orange, and the black-dyeing completed.—J. F. B.

Dyestuffs; Process for developing dyeings on vegetable fibres with diazotisable substantive—. Act.-Ges. f. Anilinfabrikation. Ger. Pat. 303,409, Apr. 4, 1917.

THE dyestuffs are diazotised on the fibre in the usual way and developed with an N-alkyl derivative of chloro-*m*-phenylenediamine. The colours so obtained are generally bluer or of a more distinctly reddish blue shade than those developed with chloro-*m*-phenylenediamine.—J. F. B.

Proteins; Purification of products of hydrolysis of — [for use as detergents, etc.]. C. Bennert, Cöpenick. Ger. Pat. 304,003, Dec. 24, 1915.

CRUDE solutions containing protalbic and lysalbic acids or their salts, such as are obtained by the hydrolysis of proteins by caustic alkalis, are treated with calcium or magnesium hydroxide or a mixture of both. These protein derivatives are useful as detergents and are also employed in the textile industry, particularly in dyeing and printing. For this purpose they have to be purified from gelatinous and other by-products which give insoluble compounds with calcium and magnesium salts.—J. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

[Sulphuric] acid mixing; Graph for —. E. C. Craven. Chem. News, 1918, 117, 217—218.

A GRAPHIC method is described for determining the proportions of oleum and C.O.V. to be mixed in making highly concentrated sulphuric acid. Two parallel side scales are provided with a slide between them. One of the scales is marked with C.O.V. concentrations in per cent. H_2SO_4 , and the other with oleum strengths in per cent. SO_3 . Unit lengths on each side correspond to the same percentage difference of SO_3 . The slide is marked with an inclined line divided into 100 parts, joining two corresponding points on the scales, e.g., 100% H_2SO_4 and 81.63% SO_3 . The slide is set with one end of the line against the desired strength of acid and the percentage strengths of the storage tanks of oleum and C.O.V. joined by a line. The intersection point on the divided line gives the reading for the relative proportions of oleum and C.O.V. to be mixed.—W. F. F.

Oxides of nitrogen; Reduction of the — to ammonia. Stability of nitric oxide. P. A. Guye and F. Schneider. Helvetica Chimica Acta, 1918, 1, 33—52.

IN Switzerland the conditions are such that oxides of nitrogen can be manufactured more conveniently than ammonia, so that a knowledge of the condi-

tions under which the former are reduced to the latter becomes necessary. The authors have carried out such an investigation, using a special apparatus in which known mixtures of hydrogen with the respective oxides of nitrogen were passed over heated reduced nickel as catalyst. In order to decompose nitric oxide under atmospheric pressure, it is necessary to keep the temperature at or above 575°C. for several hours, even in the presence of spongy platinum as catalyst. Under these conditions, and contrary to what takes place under pressure, there is no formation of nitrous oxide. The primary products of decomposition are nitrogen and oxygen; on cooling, the oxygen reacts with undecomposed nitric oxide to give nitrogen peroxide. Nitrous oxide decomposes into nitrogen and oxygen. In the reduction of nitric and nitrous oxides and nitrogen peroxide by hydrogen, with nickel as catalyst, two reactions take place simultaneously, the one giving ammonia and the other nitrogen. Both in the reduction of nitric oxide and of nitrogen peroxide, the formation of intermediate products (nitrous oxide and nitric oxide respectively) does not occur. Temperatures of 250° – 300°C. appear to be the best for the formation of ammonia. Below these temperatures the reduction takes place slowly, whilst above these temperatures the nickel gradually loses its activity and the ammonia is appreciably decomposed into its elements. Nitric oxide gives the best yields, 70% of the gas on an average being transformed into ammonia; 25–39% of nitrogen peroxide and only 3–7% of nitrous oxide is reduced to ammonia. The reduction of the oxides of nitrogen to ammonia does not, therefore, appear to be an advantageous process from the manufacturing point of view, except, perhaps, in the case of nitric oxide, where a more systematic study of the conditions may give better results.—T. S. P.

Nitrates; Gasometric determination of —. C. A. Hill. *Analyst*, 1918, 43, 217–218.

THE usual method of determining nitrates by shaking with sulphuric acid in a nitrometer filled with mercury has many disadvantages; if an external reaction flask is used, this must be filled previously with a gas which is inert towards nitric oxide. Carbon monoxide may be used for the purpose and is conveniently prepared by heating a mixture of sodium formate and concentrated sulphuric acid.—W. P. S.

Iodides; Detection of — in the presence of cyanides. L. J. Curtman and C. Kaufman. *J. Amer. Chem. Soc.*, 1918, 40, 914–917.

THE detection of iodide in presence of relatively large quantities of cyanide has been examined by comparative tests with potassium nitrite, potassium permanganate, hydrogen peroxide, and chlorine as oxidising agents. The results show that the interference of cyanide is least when potassium permanganate is employed to liberate iodine. A method is described by means of which it is possible to detect 1 mgrm. of iodide in the presence of 500 mgrms. of cyanide. The cyanide is precipitated by the addition of cobalt nitrate, and after the addition of asbestos fibre the mixture is boiled for half a minute and filtered. The filtrate and washings are then tested for iodide by the addition of 1 c.c. of chloroform, 2 c.c. of $3N\text{H}_2\text{SO}_4$, and 2 drops of 0.5% potassium permanganate.—H. M. D.

Alkali phosphates; Reaction between the — and magnesium chloride. D. Balareff. *Z. anorg. Chem.*, 1918, 102, 241–246.

THE author shows that the precipitate formed by the addition of magnesium chloride to disodium hydrogen phosphate is liable to contain alkali in the form of MgNaPO_4 , the amount of alkali depending

upon the conditions of precipitation. In saturated solutions of MgCl_2 and Na_2HPO_4 the amount is large, in dilute solutions small. When a dilute solution of magnesium chloride is added slowly to a 10% solution of K_2HPO_4 , the crystalline precipitate formed consists of practically pure $\text{MgKPO}_4 \cdot 6\text{H}_2\text{O}$. By heating to 100°C. this salt is converted into the monohydrate. When the two solutions are mixed in the reverse order, the composition of the precipitate is uncertain and variable, there being present probably $\text{MgKPO}_4\text{aq.}$, $\text{MgHPO}_4\text{aq.}$, Mg(OH)_2 , and $\text{Mg}_2(\text{PO}_4)_2$. When dilute (0.2 mol.) solutions are used, the precipitate is almost pure $\text{MgHPO}_4\text{aq.}$ The rubidium salt $\text{MgRbPO}_4 \cdot 6\text{H}_2\text{O}$ can be obtained practically pure under the same conditions as the potassium salt. (See also *J. Chem. Soc.*, Aug., 1918.)—E. H. R.

Stannic fluoride; Behaviour of solutions of —. N. H. Furman. *J. Amer. Chem. Soc.*, 1918, 40, 906–914.

STANNIC fluoride hydrolyses completely in aqueous solution in accordance with the equation $\text{SnF}_4 + 4\text{H}_2\text{O} = \text{Sn(OH)}_4 + 4\text{HF}$. From this solution the tin is precipitated by hydrogen sulphide; but this does not take place in presence of a sufficient quantity of hydrofluoric acid. From experiments made with solutions of stannic chloride, to which alkali fluorides and varying quantities of hydrofluoric acid were added, it appears that the absence of precipitation by hydrogen sulphide requires not only the presence of fluoride but also of free acid. The free acid prevents the hydrolysis of the stannic fluoride. The preparation of pure stannic fluoride by a method which involves the use of a minimum quantity of platinum ware is described. (See also *J. Chem. Soc.*, Aug., 1918.)—H. M. D.

Gold [compounds] at high temperatures and pressures; Chemistry of —. H. H. Morris. *J. Amer. Chem. Soc.*, 1918, 40, 917–927.

CERTAIN gold compounds are reduced when heated in a steel bomb in contact with water at high temperatures. Gold hydroxide is reduced at 320°C. , and reduction occurs at a lower temperature in presence of sodium or magnesium chloride. Calcium chloride retards the decomposition. Gold chloride gives metallic gold at about 370°C. , but in presence of small quantities of sodium, magnesium, or calcium chloride a temperature of 450° – 460°C. is required. Calcite and magnesite reduce gold chloride in aqueous solution at about 310°C. , but a temperature of about 500°C. is required in the presence of sodium, magnesium, or calcium chloride. The reduced gold dissolves in hot concentrated hydrochloric acid if this contains gold chloride. Aurous chloride is thereby formed and may be titrated with potassium permanganate.—H. M. D.

Spent oxide; Analysis of —. V. Hottenroth, Wentzel, E. Wolff, H. Drehschmidt, and Wirts. *Ver. deutsch. Gaswerke A.-G. Z. angew. Chem.*, 1918, 31, 127–128.

A SERIES of criticisms on the method of determining sulphur in spent oxide (this *J.*, 1918, 240 A). Hottenroth points out that substances other than sulphur are extracted by carbon bisulphide. Washing the extracted sulphur with ether does not purify the sulphur completely. Wentzel recommends the extraction of the sulphur by carbon tetrachloride in a modified Soxhlet apparatus, Wolff converts the extracted sulphur into sulphate by fusion with sodium carbonate and potassium nitrate, and precipitates the sulphate with barium chloride, and Drehschmidt is also of opinion that the sulphur should be converted into sulphate and determined as such, since purification by ether is unsatisfactory.—W. P. S.

PATENTS.

Sulphuric acid; Process of concentrating —. Concentrating apparatus. (A) I. Hechenbleikner, Charlotte, N.C., (B) I. Hechenbleikner, Assignor to Southern Electro-Chemical Co., New York. U.S. Pats. (A) 1,264,182 and (B) 1,264,509, Apr. 30, 1918. Dates of appl. (A) Feb. 10, 1917, (B) Nov. 6, 1914.

(A) A BATH of the acid is maintained at a temperature below its boiling point, and hot air is passed through the liquid to absorb and carry off volatile impurities. Weak acid is admitted to the bath, after being heated by the gases escaping from the bath. (B) The apparatus comprises means for leading the hot gas into the bath in a number of separate streams at a point below the surface, the current of weak acid being fed from a point above the container to replenish the bath, and being heated by the escaping gas.—B. N.

Sulphuric acid; Denitration of —. I. Hechenbleikner, Charlotte, N.C., Assignor to The Southern Electro-Chemical Co., New York. U.S. Pat. 1,264,512, Apr. 30, 1918. Date of appl., Feb. 10, 1917.

SULPHURIC acid, containing nitrogen oxides, is sprayed into a current of steam, and oxygen is introduced into the resulting gases to produce nitric acid fumes, the latter being subsequently condensed.—B. N.

Gases [sulphur dioxide]; Method and apparatus for segregating and recovering —. Art of and apparatus for treatment of corrosive gases. F. A. Eustis, Milton, Mass. U.S. Pats. (A) 1,265,892 and (B) 1,265,893, May 14, 1918. Date of appl., Dec. 19, 1917.

(A) In a process for recovering sulphur dioxide from furnace gases, the solution obtained by scrubbing the latter with water is subjected to the combined action of heat and vacuum, and the sulphur dioxide liberated is deprived of water vapour by means of refrigerating and desiccating agents. (B) To minimise corrosion of apparatus by acid gases containing condensed water (e.g. the moist sulphur dioxide obtained in the foregoing process), the gas is deprived of water by stages, in each of which the gas is first heated to above the dew point of the contained water vapour.—W. E. F. P.

Hydrochloric acid from gaseous chlorine and hydrogen; Process of obtaining —. C. W. Baumann, Düsseldorf-Unterrath. Ger. Pat. 305,306, July 31, 1917. Addition to Ger. Pat. 301,903.

Gaseous hydrogen chloride is added to the mixture of chlorine and hydrogen introduced into the explosion cylinder as described in the chief patent. This prevents the overheating of the explosion motor and thus enables the process to be carried out continuously.—C. A. M.

Compounds of potassium and aluminium; Recovery of soluble — from silicates. B. F. Halvorsen, Christiania, Norway. Eng. Pat. 107,012, May 30, 1917. (Appl. No. 7745 of 1917.) Under Int. Conv., May 30, 1916.

A MIXTURE of finely divided alkali aluminium silicate (felspar) and calcium cyanamide is heated, either to about 650° C. in the presence of superheated steam, or under pressure with water in an autoclave to above 100° C. The addition of salts, e.g., chlorides, nitrates, sulphates, etc., facilitates the reaction. When the ammonia has been driven off, the solution is filtered, neutralised with an acid, e.g., carbonic acid or nitric acid, the precipitated alumina is filtered off and the solution evaporated until crystallisation begins. A comparatively pure potassium salt separates out on cooling.—L. A. C.

Silicon-bearing earths, rocks, minerals, and compounds; Process for decomposing —. A. D. Hone, Peterborough, Canada. Eng. Pat. 116,118, May 9, 1917. (Appl. No. 6602 of 1917.)

THE finely divided material is mixed with a solid compound containing fluorine in sufficient quantity to remove the silicon as silicon fluoride, and an acid capable of decomposing the compound—e.g. sulphuric acid—either with or without the application of heat. The silicon fluoride formed is passed into water, thereby forming silica and hydrofluosilicic acid. The hydrofluosilicic acid is treated with another compound—e.g. the potassium compound obtained in the decomposition—thus forming a fluosilicate which may be used in the decomposition of other material.—L. A. C.

Alkalis and alumina; Method of obtaining — from silicates containing them. F. A. Rody, Johnson City, Tenn., Assignor to The Metallurgical Co. of America, New York. U.S. Pat. 1,263,705, Apr. 23, 1918. Date of appl., May 18, 1915. Renewed July 13, 1917.

A MIXTURE of felspar, leucite, or similar silicate, and an alkaline-earth oxide is heated to a sintering temperature, the clinker is digested with boiling water, and the dilute solution of alkali aluminate so obtained is used to treat further quantities of clinker until it becomes sufficiently concentrated.

—A. B. S.

Salt manufacture; Method and system of —. C. L. Well, Port Huron, Mich. U.S. Pat. 1,261,331, Apr. 2, 1918. Date of appl., May 10, 1917.

Is a method of producing salt from brine the latter is evaporated, first at the boiling-point to form small crystals, and then below the boiling-point to produce relatively large crystals. Of the two evaporators employed, the second is egg-shaped in cross-section and provided with means for regulating the depth, and hence the surface area, of liquid.—W. E. F. P.

Ammonia; Production of —. P. R. Hershman, Assignor to Armour Fertilizer Works, Chicago. Ill. U.S. Pat. 1,261,526, Apr. 2, 1918. Date of appl., Dec. 22, 1914.

ALUMINIUM nitride, alone or mixed with calcium oxide, is treated with superheated steam while maintained at a temperature approximating to but lower than 600° C.—W. E. F. P.

Bleach; Method of making high-strength —. K. P. McElroy, Washington, D.C. U.S. Pat. 1,261,572, Apr. 2, 1918. Date of appl., Aug. 30, 1917.

From the products of reaction between steam and chlorine at about 100° C., aqueous hydrochloric acid is removed by condensation, and the residual vapour (hypochlorous acid) is absorbed by caustic alkali.—W. E. F. P.

Zinc chloride; Production of —. *Producing zinc chloride from ores*. F. K. Cameron and J. A. Cullen, Salt Lake City, Utah, and R. W. Hyde, New York, Assignors to American Smelting and Refining Co., Salt Lake City. U.S. Pats. (A) 1,261,695 and (B) 1,261,696, Apr. 2, 1918. Dates of appl., June 18 and July 17, 1917.

(A) OXIDISED zinc ore is treated with sufficient strong hydrochloric acid to combine with the bases present. The mass is then evaporated to dryness, maintained at about 300° C. until evolution of hydrochloric acid ceases, and treated with water to dissolve the zinc chloride. (B) Oxidised zinc ore containing lead is mixed with a metal chloride, and the mixture is heated to volatilise the lead as chloride. Zinc chloride is then recovered from the residue by leaching.—W. E. F. P.

Kelp-dryer. S. R. Oppenheim, Keeler, Cal. U.S. Pat. 1,266,041, May 14, 1918. Date of appl., June 7, 1917.

A HORIZONTAL rotary cylinder is provided internally with lateral vanes between which a number of parallel cross plates are disposed obliquely. The vanes extend along the entire length of the cylinder and are inclined near the feed end, their inner edges being advanced in the direction of rotation so as to form lifting pockets. The kelp is caused to travel longitudinally by the rotation of the cylinder.

—W. E. F. P.

Steatite; [Electro-osmotic] process of removing liquid [water] from —. B. Schwerin, Assignor to Elektro-Osmose A.-G. (Graf Schwerin Ges.), Frankfurt, Germany. U.S. Pat. 1,266,330, May 14, 1918. Date of appl., Nov. 11, 1914. Renewed Oct. 24, 1917.

STEATITE is finely subdivided in the presence of an electrolyte suitable for bringing the solid body into the sol condition, and of a colloid body (e.g. sodium silicate), and then subjected to electro-osmotic treatment.—W. E. F. P.

Chalk; Process of making light precipitated —. N. Statham, Hastings-upon-Hudson, Assignor to Industrial Chemical Co., New York. U.S. Pat. 1,266,339, May 14, 1918. Date of appl., July 25, 1917.

PURE hydrated lime liquor, having a density between 25° and 35° Tw. (sp. gr. 1.125–1.175), is sprayed repeatedly through an atmosphere rich in carbon dioxide and under a pressure of 60–80 lb. per sq. in. The liquor is then filtered and the residue dried at 110°–120° C. without agitation.

—W. E. F. P.

Exchange silicates; Process of making —. *Process of making exchange bodies*. G. Rudolf, London, Assignor to The Permutit Co., New York. U.S. Pats. (A) 1,263,706 and (B) 1,263,707, Apr. 23, 1918. Dates of appl., Dec. 9 and 22, 1916.

(A) A rocky material containing acid-soluble silicates is extracted first with hydrochloric acid and then with soda solution. The acid solution is neutralised with the soda solution, producing a precipitate which is dried at a low temperature. (B) A solution of an alkaline silicate is mixed with such a proportion of a solution of an aluminium salt containing an acid radicle that the mixture is distinctly alkaline to methyl orange, but not to phenolphthalein.—A. B. S.

Gases [containing phosphorus pentoxide and silicon fluoride]; Condensing — *from electric furnaces. Cooling and condensing gases*. I. Hechenbleikner, Charlotte, N.C., Assignor to Southern Electro-Chemical Co., New York. U.S. Pats. (A) 1,264,510 and (B) 1,264,511, Apr. 30, 1918. Date of appl., Feb. 10, 1917.

(A) GASES containing phosphorus pentoxide and silicon fluoride are treated to produce phosphoric acid and hydrofluosilicic acid, by first removing dust from the gases whilst they are in a heated state, and then electrically precipitating the phosphorus pentoxide as a solid, which is brought into contact with water to form phosphoric acid. The residual gas is passed through an absorption and condensation system in contact with water to form hydrofluosilicic acid. The acid is finally concentrated. (B) The hot gases are passed through a chamber in contact with water-cooled units to cool them and separate dust, and are then treated as described above.—B. N.

Mono- and diammonium phosphate; Manufacture of —. I. Hechenbleikner, Charlotte, N.C., Assignor to Southern Electro-Chemical Co., New York. U.S. Pats. (A) 1,264,513 and (B) 1,264,514, Apr. 30, 1918. Date of appl., Feb. 10, 1917.

(A) DILUTE phosphoric acid, containing 35 to 43% P_2O_5 , is showered in a downward direction, and then collected to form a bath, and ammonia gas is introduced in divided streams at a point below the surface of the bath. The resulting gases flow from the bath as an upward counter-current into contact with the downward flow of acid to the bath. The heat of neutralisation is used to evaporate water from the bath and produce dry, non-hygroscopic, ammonium phosphate crystals. (B) The stream of phosphoric acid is showered downwards to preheat it by the escaping gas, and the liquid is conducted in a stream into contact with a stream of ammonia gas flowing in the opposite direction. The resulting crystals are dried by the conjoint effect of the heat of neutralisation and heat applied externally by means of an air blast.—B. N.

Boron derivative of pyrophosphoric acid; Manufacture of a [non-hygroscopic] —. B. Levin, Hale, Chester. Eng. Pat. 116,735, May 16, 1917. (Appl. No. 7015 of 1917.)

Pyrophosphoric acid (or orthophosphoric acid) is heated to 250° C., and a boron compound, e.g., boric anhydride, boric acid, or metaboric and/or pyroboric acid, added in such quantity that one atom of boron is provided for each two atoms of phosphorus. Heating is continued, the temperature being raised if necessary, until the mass is worked up to a homogeneous paste, which is run into trays and dried in a heated oven. The product, a pyrophosphoboric acid, having the formula $BH_2P_2O_6$, is non-hygroscopic, and may be ground to a powder or dissolved in water and converted into salts.

—L. A. C.

Chlorides; Electrolysis of — [and production of chlorohydrocarbons]. Manufacture of alkalis [and chlorohydrocarbons]. K. P. McElroy. Assignor to Chemical Development Co., Washington, D.C. U.S. Pats. (A) 1,234,535 and (B) 1,264,536, Apr. 30, 1918. Dates of appl., (A) Dec. 9, (B) June 22, 1915.

(A) An aqueous solution of a chloride is electrolysed in a suitable chamber, at a temperature about 100° C., the alkali formed being removed and recovered. During the electrolysis, an olefine, oil gas, or unsaturated hydrocarbon, is conveyed into the vicinity of the anode at a rate sufficiently rapid to combine with the chlorine as quickly as it is produced. The vapours of the chlorinated product and aqueous vapour are cooled to condense and return the aqueous distillate, and the vapours are then further cooled to collect the chlorinated product. (B) A chloride solution is electrolysed in a thin layer between a pair of parallel diaphragms separating the anode and cathode, and during the electrolysis the anode is maintained in an atmosphere of an olefine or oil gas.—B. N.

Potassium salts from mother-liquor salts; Process of separating —. G. Sterling, Salt Lake City, Utah. U.S. Pat. 1,264,572, Apr. 30, 1918. Date of appl., Sept. 17, 1917.

An intimate mixture of mother-liquor salts (from brine) with silica and limestone is heated, with stirring, to effect combination between the silica and the magnesium and sodium (present as sulphate) of the mother-liquor salts and the calcium of the limestone. The mixture is then further heated to volatilise potassium salts and sodium chloride, whereby a condensed product relatively rich in potassium and free from magnesium salts is obtained. The silica of the original mixture may be replaced by a potassium-bearing silicate, in which case the non-volatile residue is treated to convert the insoluble potassium of the silicate into a soluble salt, and re-heated to recover the latter.

—W. E. F. P.

Nitrogen compounds from metal carbides and nitrogen; Process of obtaining —. V. Thrane, Christiania. Ger. Pat. 302,582, Oct. 29, 1916. Under Int. Conv., Nov. 29, 1915.

That part of the apparatus in which the metal carbide reaches the reaction temperature is constructed in the form of an inclined plane, so that when the reaction is complete the vessel containing the charge falls by gravity, and is thus automatically withdrawn to a cooler part of the apparatus with the object of preventing reversal of the reaction. The apparatus may also contain a cylindrical space having in its floor a turntable upon which the reaction vessels rest, and by means of which they may be conveyed to the inclined plane.

—C. A. M.

Sulphites; Process of manufacturing solid neutral — from bisulphite solutions. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 304,867, Jan. 5, 1917.

A SOLUTION of a bisulphite is decomposed by means of oxides or carbonates suspended in the mother liquor from which the sulphite has separated in a previous operation. When spent the mother liquor is renewed by saturation with sulphur dioxide.—C. A. M.

Elements of the air; Process for the separation by liquefaction and rectification of the —. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude, Paris. Eng. Pat. 114,817, Oct. 17, 1917. (Appl. No. 15,082 of 1917.) Under Int. Conv., Apr. 13, 1917.

IN Eng. Pat. 3326 of 1911 (this J., 1912, 335) is described a method of separating pure oxygen and pure nitrogen from liquid air, but with the disadvantage of a poor yield of oxygen, a large part of this gas leaving the apparatus mixed with nitrogen and argon. In order to avoid this loss, the liquid oxygen from the main rectifying column is introduced only towards the lower plates of the secondary rectifying column, and the escaping gases, after passing through a heat exchanger, are compressed and returned to a nest of tubes immersed in liquid oxygen at the bottom of the latter column, in which they are liquefied, with the exception of a small residue of nitrogen. The liquid is then passed up a tube which enters the secondary rectifying column on a level with the exit tube, and, as rectification proceeds, the escaping gases become poorer and poorer in oxygen. If the gaseous residue in the nest of tubes corresponds to the proportion of nitrogen accompanying the liquid oxygen—e.g., 2 or 3%—the escaping gas, part of which is extracted after leaving the heat exchanger, consists almost entirely of oxygen and argon. Of the air introduced into the apparatus, about four-fifths should be liquefied in a system of coils in the main column, and about one-fifth by the liquid oxygen in the bottom of the secondary column, whence the liquid produced is introduced into the main column to compensate for loss of liquid oxygen through the tube conveying the liquid to the lower part of the secondary column.

VIII.—GLASS; CERAMICS.

Optical glass; Nomenclature of —. W. Zschokke, Z. f. Instrumentenkunde, 1918, 38, 49–54.

THE various systems of nomenclature of optical glasses are confusing and irrational, being based on historical considerations or chemical character without any relation to the optical properties. The new Sendlinger optical glass works, Berlin, has introduced a system which is intended not only to classify but to give an indication of optical properties also. The glasses are divided into four groups, "Kron," "Flint," "Barion," and "Barint," the last two names being contractions of "Barium-Kron" and "Barium-Flint," and covering the newer barium silicate glasses. The individuals in these groups are characterised by affixing two numbers which indicate the optical properties—e.g., Kron 567/628 indicates a crown glass of refractive index 1.567 and dispersive power (the ν of Abbe) 62.8.—H. J. H.

Silica bricks; Composition of refractory —. J. S. McDowell. Eng. and Min. J., 1918, 105, 954–956.

THE thermal conductivity of silica bricks is, according to Dudley, 25% greater than that of fireclay bricks of good quality. The greater part of the expansion which silica bricks undergo on burning is permanent and is due to the inversion of quartz. The temporary or true thermal expansion occurs largely over a narrow range of temperature and to it is attributed the tendency of silica bricks to spall. Bricks made of Medina quartzite from Huntingdon County, Pa., were subjected to eight and ten burnings respectively. Expressed in per cent. by volume their mineral compositions were: After 8 burns: silicates 14, cristobalite 33, tridymite 53%; after 10 burns: silicates 11, cristobalite 28, tridymite 61%. These results together with others obtained previously are shown graphically. The percentage of "quartz plus silicates" reaches an approximately constant value of 13% after the third burn and probably the whole of this 13% represents silicates formed by the lime used as bond and the impurities in the raw material. A completely inverted brick should contain about 87% tridymite and 13% silicates. Apparently 16 or 17 burnings, or one continuous burning for a month, would be needed to reach this composition, so that the cost is prohibitive. So far as permanent expansion is concerned, there is little advantage in more than one burning and, for practical purposes, none after the third burning. A silica brick made of Baraboo quartzite contained: quartz plus silicates 67%, cristobalite 27%, tridymite 6%; a brick of Medina quartzite contained: quartz plus silicates 25%, cristobalite 71%, tridymite 4%. The difference is attributed to differences in the

texture of the quartzites. The Baraboo quartzite being much coarser in grain than the Medina quartzite it cannot invert so rapidly. Whilst considering Wernicke and Wildschrey's statement that ordinary quartzites do not produce good silica bricks as too sweeping, the author confirms their general conclusion that the finer grained quartzites with a cement of amorphous silica are the most suitable for making bricks. He also confirms their statement that the selection of rock of the proper texture offers greater possibilities for the production of the best (tridymite) bricks than any alteration in the process of manufacture. A coarse texture brick spalls less than one composed of fine grains, but insufficient grinding may induce other defects. As there are often wide variations in the textures of quartzites of the same geological location, the averages of a sufficiently large number of grain-size measurements should be taken.—A. B. S.

Porcelain and magnesia; Electrical resistivity of — at high temperatures. P. H. Grace. Amer. Electrochem. Soc., Apr.—May, 1918. [Advanced proof.] 8 pages.

THE porcelain used for sparking-plug insulators is unsatisfactory when employed as an insulator at 1000° C. because of current-leakage. Test-pieces, about 1 in. by 0.8 in., of electrically fused magnesite (containing 94% MgO) and of the same magnesite, fused electrically, then crushed to powder, moulded under heavy pressure, and burned at 1700° C., were placed on a grid of square nickel wire supported on an asbestos pad and loaded with a weight of about 11 lb., the weight being placed on an asbestos pad supported on a nickel grid. The loaded test-pieces were heated in a muffle furnace at 1000° C. for 24 hrs. and allowed to cool quickly. The temperature was then adjusted to the required value and time allowed for the test-piece to attain a uniform temperature. After this, an electric current of constant voltage (120 volts) was applied through the grids at each end of the test-piece and the current was measured at intervals. After a sufficient number of readings had been taken, the current was reversed and further readings were made. The results, plotted graphically, showed that the apparent resistivity is a function of the time during which the current is applied, the final value in some cases being several times the initial one. When the current was reversed the resistivity was lowered, but gradually rose to its former value. This occurred even after repeated reversals. Fused magnesite has a higher resistivity and a higher ratio of initial to final resistivity at each temperature than a piece of the porcelain used for sparking plugs, and the resistivity attains a constant value more quickly. This appears to be due to the porcelain being a complex mixture of mutually soluble oxides, whereas the magnesia is a relatively pure material. The moulded sample of magnesia had slightly lower resistivity values than the other sample, but the difference was not marked; it may be due to the introduction of impurities during grinding and firing. At 910° and 990° C., the porcelain behaved like a storage battery and on stopping the current it gave an electromotive force of 0.7 volt, in the opposite direction, which decayed slowly, but was appreciable after half an hour. This behaviour suggests electrolytic phenomena.

Magnesia-silica mixtures; Crushing strength of — at high temperatures. O. L. Kowalke and O. A. Hogen. Amer. Electrochem. Soc., Apr.—May, 1918. [Advance copy.] 11 pages.

MIXTURES of magnesia and silica in various proportions were made into cylinders 2.16 in. high by

1 in. diam., fired at 2100° C., and afterwards reheated in an electric furnace at the rate of 10° C. per min. under a load of 66.5 lb. per sq. in., the temperature at which failure occurred being noted. The heat-treatment during the first firing and the rate of heating under load had considerable influence on the result. The best results were obtained with mixtures containing 7 to 8% of silica; these failed at 1870° C., whilst pure magnesia failed at 1680° C. The failure of cylinders of pure magnesia was gradual; that of the mixtures was abrupt. When the cylinders were fired at or above 1900° C. they lost weight owing to the reaction between them and the carbon supports used to transmit the pressure. Cylinders fired at 1800° C. contained periclase enveloped in and bonded with forsterite. Below 1500° C. there was little forsterite and the strength was low; at 2000° C. the forsterite collected into separate crystals of larger size and consequently the strength of the cylinders was reduced. When the cylinders were heated and then quenched in cold water, the formation of forsterite was repressed though some was still formed in the grain-boundaries of the periclase.—A. B. S.

PATENTS.

Glass furnaces. A. F. Peeters, Lingedijk, Holland. Eng. Pat. 116,477, Feb. 11, 1918. (Appl. No. 2439 of 1918.)

IN a rectangular tank furnace the "burner" is placed at the end of the working space, the gases travelling first through the working space and then through the melting space, instead of in the opposite direction, as is customary. Advantages of the new arrangement are that the glass is melted on the counter-current principle, the solid materials being fed into the coolest part of the furnace and the molten glass flowing gradually to the zone of the highest temperature; the distribution of heat in the furnace allows the glass to be melted more efficiently; the burning fuel (e.g. tar) enters so hot a portion of the furnace that no deposition of carbon occurs and no undesired coloration of the glass need be feared.—A. B. S.

Glass and method of making it. E. W. Enequist, Brooklyn, N.Y. U.S. Pat. 1,261,015, Apr. 2, 1918. Date of appl., July 20, 1917.

FUSED lepidolite (lithia mica) is added to a glass batch and the whole is then fused so as to produce a glass of superior strength, temper, and appearance.—A. B. S.

Ceramic and like ware; Manufacture of [lustrous] —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Eng. Pat. 113,777, Sept. 27, 1917. Under Int. Conv., Feb. 28, 1917. (Appl. No. 13,963 of 1917.)

LUSTROUS coatings on ceramic ware are produced by applying the coating material in the form of a colloidal sol and then firing the ware to a temperature below the melting point of the coating. Suitable coating materials are clays, many silicates, zirconia and other oxides, carborundum, etc. These may usually be converted into the sol state by suspending them in water containing a small proportion of an electrolyte and allowing the coarser particles to settle; by the method described in Eng. Pat. 14,235 of 1912 (see Addition to Fr. Pat. 426,072; this J., 1912, 1189); or by alternate treatment with acids and alkalis. The degree of lustre obtained varies with the degree of dispersion of the colloid.—A. B. S.

Kiln; Sectional —. R. H. McElroy, Assignor to International Clay Machinery Co., Dayton, Ohio. U.S. Pat. 1,264,316, Apr. 30, 1918. Date of appl., July 2, 1917.

A RECTANGULAR kiln, having a perforated sole, is provided with a number of sections, arranged longitudinally, each section having bag-walls at the sides, forming conduits for the heated air and the products of combustion, together with longitudinal connecting flues between the sections, and lateral hot air flues or *vice versa*.—A. B. S.

Kiln; Compartment —. R. H. McElroy, Assignor to International Clay Machinery Co., Dayton, Ohio. U.S. Pat. 1,264,317, Apr. 30, 1918. Date of appl., Sept. 1, 1917.

A KILN is divided into compartments, which are connected by flues not in alignment, the length of each flue being greater than the width of one compartment, so that several compartments may be heated simultaneously. The compartments are also connected by air flues, which in turn are connected by lateral flues, and by means of a hood the lateral flues may be connected with either the main draught flue or the waste-heat flue through uptake flues.

—A. B. S.

Kiln-system. J. T. H. Warwood, Wadsworth, Ohio. U.S. Pat. 1,264,722, Apr. 30, 1918. Date of appl., July 7, 1917.

A SERIES of round kilns with fire-boxes, perforated hearths, and vertical flues is connected through the perforated hearths with an upper, central, longitudinal flue, and the vertical flues are connected with a lower, central, longitudinal flue. These upper and lower flues are connected to each other by means of damper-controlled ports, an upper lateral flue, and transverse flues meeting the upper central flue between the ports and the dampers. A lower lateral flue is connected to the lower central flue through a transverse passage and to an exhaust. The portions of each kiln connected to the upper and lower central flues respectively may be connected *vice versa*.—A. B. S.

Vitreous enamel; Production of articles enamelled with a —. K. Waga, Brooklyn, N.Y., U.S.A. Eng. Pat. 116,361, June 11, 1917. (Appl. No. 8319 of 1917.)

SHEETS of aluminium or its alloys are heated to 500°–700° C. and covered with a thin layer of finely powdered glass, enamel, or other vitrifiable material, so as to form an adherent coating which will not crack when the sheets are afterwards made into articles of the desired shapes.—A. B. S.

(A) *Aluminous abrasive.* (B) (C) *Aluminous abrasive and process of making the same.* L. E. Saunders and R. H. White, Niagara Falls, N.Y., Assignors to Norton Co., Worcester, Mass. U.S. Pats. (A) 1,263,607, (B) 1,263,709, and (C) 1,263,710, Apr. 23, 1918. Dates of appl., (A) Dec. 26, (B) and (C) Aug. 2, 1917.

(A) A CRYSTALLINE, aluminous abrasive containing material quantities of an acid oxide (as silica) and an alkali, so proportioned as to yield a relatively weak abrasive grain as compared with aluminous grains of similar acid oxide (silica) content, but free from alkali. (B) A crystalline abrasive with properties similar to (A) is made by fusing a mixture of alumina and a sodium compound in an electric furnace. The sodium compound is

vaporised and causes individual crystals of the solidified product to be perforated or cellular. (c) An abrasive with properties similar to (a) and (b) is made by mixing bauxite with a small proportion of an alkali compound, with or without carbon, and fusing in an electric furnace.—A. B. S.

β-Alumina; Product [abrasive] containing — and process of preparing the same. L. E. Saunders and R. H. White, Niagara Falls, N.Y., Assignors to Norton Co., Worcester, Mass. U.S. Pat. 1,263,798, Apr. 23, 1918. Date of appl., Mar. 2, 1917.

An aluminous material is fused with sufficient sodium carbonate to convert a material proportion, for example, more than half, of the alumina into the β-modification. The product may be used as an abrasive.—A. B. S.

Earthenware and like articles; Cranks for supporting — during the process of firing. W. P. Edwards, and J. Edwards and Sons, Ltd., Stoke-on-Trent. Eng. Pat. 116,241, Feb. 13, 1918. (Appl. No. 2580 of 1918.)

PATENTS.

Concrete or cement substances, and the composition thereof. L. Linder, London. Eng. Pat. 114,641, Mar. 6, 1917. (Appl. No. 3317 of 1917.)

CONCRETE or cement substances are made by intimately mixing Portland cement or the like; vegetable matter such as moss, turf, seaweed, cork, or fibres; finely divided iron ore or other metallic ore; a binder consisting of 5 kilos. of fresh quick-lime, 3 kilos. of aluminium sulphate, and 1 cubic metre of water; and fatty matter introduced in the form of strings of jute or other textile material or fragments of pumice, cork, etc., impregnated with oil or grease. The binder is prepared in a mechanical mixer, the vegetable matter is added, and then the cement is introduced slowly and is followed by the ore, the mixing being continued without intermission during the whole of the time. The impregnated strings or other material are arranged in layers in the composition whilst it is still soft or they may be arranged in conjunction with the ordinary reinforcement. As the cement or concrete dries, the fatty matter gradually permeates it, producing a structure of great resiliency and resistance to shock.—A. B. S.

Cement from blast-furnace slag; Manufacture of —. A. A. J. Deckers, Paris. Eng. Pat. 114,791, Dec. 11, 1917. (Appl. No. 18,280 of 1917.)

GRANULATED slag is ground under water, dried in a centrifuge until it contains less than 7% of water, and then mixed with a suitable proportion of ground lime and the mixture ground to the requisite fineness. By the preliminary grinding of the slag the enmeshed water is liberated and its removal facilitated; if the water were not removed, the cement mixture would set hard in the mill and could not be ground.—A. B. S.

Plaster composition. P. S. Anneke, Duluth, Minn., Assignor to Celite Products Co., Los Angeles, Cal. U.S. Pat. 1,261,747, Apr. 30, 1918. Date of appl., Aug. 21, 1916.

HYDRATED lime and amorphous silica (kieselguhr) are ground together to form a plaster composition.—A. B. S.

Plaster composition. H. Blumenberg, jun., Los Angeles, Cal., Assignor to F. Blumenberg, New York. U.S. Pat. 1,266,200, May 14, 1918. Date of appl., Oct. 1, 1917.

The material contains equal parts of dead-burnt gypsum and hemi-hydrated calcium sulphate.

—W. E. F. P.

Magnesite; Process for obtaining artificial — for the production of artificial stone, cements, pigments, etc. Harburger Chem. Werke Schön & Co., and W. Daitz, Harburg. Ger. Pats. (a) 305,448 and (b) 305,449, Mar. 3; (c) 305,446, Oct. 10, and (d) 305,447, Dec. 1, 1914.

(A) In the usual method of recovering magnesia by the addition of a mixture of lime and magnesia to a liquor containing magnesium chloride, residues containing calcium hydroxide are produced which react very slowly and delay the process of recovery. Magnesium hydroxide also separates very slowly towards the end of the process. These difficulties are overcome by applying pressure and heat to the whole of the mixture or to the liquid obtained after separating the bulk of the precipitated magnesia. A pressure of 1–3 atmospheres is usually sufficient. (b) In the production of magnesia as free as possible from lime, and therefore suitable for pigments, excess of precipitant is used and the residual liquor then contains some magnesium chloride as well as calcium chloride. This waste liquor is used to dilute a further quantity of magnesium chloride liquor previous to the treatment of the latter with a mixture of lime and magnesia, and its content of magnesium chloride thus utilised. (c) To a liquor containing magnesium chloride is added a mixture of lime and magnesia containing lime equivalent to the magnesium chloride. The mixture is stirred thoroughly and heated, with constant stirring, until a stiff paste is produced. The solid matter is then separated, dried and carefully calcined. The calcined magnesia possesses a strong binding power which makes it specially useful in the manufacture of artificial stone and cement. (d) Burned dolomite or other mixture of lime and magnesia is treated with sufficient water to slake it partially and is then added to a liquor containing magnesium chloride so as to produce a slurry containing magnesium oxide and hydroxide. The suspended matter is separated, dried, and carefully calcined. The partially hydrated mixture of lime and magnesia may be sifted before use so as to eliminate the coarser particles. The use of a partially hydrated mixture yields a material of superior shaping and binding power and permits a magnesium chloride liquor of higher concentration to be employed.—A. B. S.

Cementing materials; Method of manufacturing — and products thereof. H. W. Charlton, Jones Point, N.Y., U.S.A. Eng. Pat. 115,946, June 27, 1917. (Appl. No. 9249 of 1917.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steels; Critical points of pure carbon —. P. Bardenheuer. *Ferrum*, 1917, 14, 129–133, 145–151. *Z. angew. Chem.*, 1918, 31, Ref., 170.

THE A₁ point occurs in all plain carbon steels at 740° C. A₁1, however, rises from 706° C. for almost carbonless iron to 722° C. for the eutectoid composition, after which it remains constant. The hysteresis in the A₁ point is thus apparently related to the ferrite present. A₂ and A₂2 are found as separate points up to 0.41% C, and both occur at 770° C. irrespective of the carbon content. The β — γ change for a steel with 0.06% C occurs at 911° C., A₃ being at 886° C. The A₃ hysteresis, it is stated, decreases from 25° C. for pure iron to nil for 0.9% C. The A₃ point is lowered rapidly by carbon when present up to 0.41%, the γ — α change being then lowered more slowly to 0.9%, the rates being 3:1. The eutectic point is given as 0.85% C. —F. C. Th.

Steel; Magnetic analysis of carbides found in different kinds of —. T. Ishiwara. *Sci. Rep. Tôhōkn Imp. Univ.*, 1918, 6, 285–294.

THE magnetic properties of cementite obtained from various kinds of steel have been examined, and evidence of the decomposition of the carbide is afforded by the sudden increase in the susceptibility between 650° and 730° C. After the heat treatment the presence of magnetite formed by the oxidation of the cementite is recognised by the transformation which occurs at 580° C. Natural magnetite and chemically prepared magnetic oxide are differentiated by their transformation temperatures, these being 580° and 510° C. respectively. Separation of cementite from the solid solution of an eutectoid steel begins at about 130° C., and is nearly complete at 360° C. The three ranges of temperature separated by 130°, 360°, and 600° C. correspond respectively with martensite, troostite, and sorbite. According to magnetic observations, martensite is a solid solution of the carbide in γ -iron, whilst troostite represents the stages in which cementite separates out in colloidal form, the limit to this series being reached at 360° C., with the formation of osmondite. Sorbite has the same magnetic susceptibility as pearlite. Residues from quenched specimens contain only a small quantity of cementite, but the amount of this increases with the tempering temperature up to 360° C. The residues are very reactive and ignite in the air, but the oxidisability decreases as the tempering temperature increases. The examination of the carbides from special steels has shown that the double carbides of iron and manganese and of iron and tungsten are magnetic, whilst the residues from chromium steel and high-speed tool steel are paramagnetic.—H. M. D.

Iron-carbon alloys; The processes of melting and freezing in —. R. Ruer and F. Goerens. *Ferrum*, 1917, 14, 161–177. *Z. angew. Chem.*, 1918, 31, Ref., 168.

THE “equilibrium” temperature for the melting and freezing of the cementite eutectic of white pig iron is given as 1145° C., and that of the graphite eutectic, i.e., grey iron, as 1152° C. It is shown that in pure iron-carbon alloys the formation of graphite occurs both on heating and cooling as a result of the presence of the liquid phase, cementite or solid solution being of minor importance. The precipitation occurs directly from the liquid phase and not by decomposition of a previously separated

crystalline phase. The “equilibrium” temperature for the formation of pearlite, i.e. the mean of A₁ and A₁1, is given as 721° C. corresponding to 0.9% C.—F. C. Th.

Carbon steels; Determination of the velocities of cooling necessary to realise the hardening of —. P. Chevenard. *Comptes rend.*, 1918, 166, 682–685.

USING the photographic method previously described (see this J., 1917, 881) the author has studied the cooling curves of steels containing from 0.2 to 0.8% carbon. Different rates of cooling were obtained by using cooling atmospheres consisting of varying proportions of nitrogen and hydrogen. For different temperatures of heating, plotting carbon content against velocity of cooling, the curves which mark the limit of appearance of martensite were determined. As the carbon content decreases from 0.8%, the maximum velocity of annealing (marked by first appearance of martensite) relative to a given temperature of heating, θ_c , increases at first slowly, but below 0.5% carbon it rises with extreme rapidity. Thus it is impossible to lower to any marked extent by simple cooling the temperature of transformation of pure iron. For high carbon steels, A₁ falls rapidly to a very low value when θ_c rises and consequently it is possible to define, for a given mode of cooling, a minimum temperature of complete hardening θ_1 . When, however, the carbon content is low, A₁ and A₂ tend slowly towards distinct limits according to the method of cooling. There is thus, for each velocity of cooling, a maximum intensity of hardening, which is greater as the velocity is higher. In other words, in regard to efficiency of hardening, it is possible to compensate, to a certain extent, for an insufficient speed of cooling by increasing the temperature of heating, but this compensation is less possible the lower the carbon content of the steel. —W. G.

Steel; Macrostructure of —. A. Portevin and V. Bernard. *Rev. Mét.*, 1918, 15, 273–280.

THE macrostructure of steel, which is determined by the first freezing out from the liquid state, is best developed by etching a polished section with Stead's reagent (this J., 1915, 616) as modified by Le Chatelier (this J., 1915, 1056; 1917, 1051), and then lightly repolishing. The reagent brings out well the original dendritic structure as a result of the changes in the phosphorus content. An identical structure in cast and unworked steel is shown by sulphur printing. The etching also enables the exterior elongated crystallisation of a casting or ingot to be distinguished from the internal equi-axed type. The macrostructure of forged steels shows the deformed dendrites drawn out in the direction of the elongation. When the working has been sufficient, the dendrites are drawn out into a bundle of parallel lines in a longitudinal section. Transversely the initial structure is retained but on a much finer scale. The longitudinal structure enables the degree of forging to be estimated. Heat treatments used in practice do not modify the macrostructure. Heating to 850° to 900° C. for 3 to 6 days results in diffusion occurring, with the result that the primary structure is lost. —F. C. Th.

Mild steel; Influence of hot working on the mechanical properties and structure of low carbon —. F. Wüst and F. Huntington. *Stahl u. Eisen*, 1917, 37, 829–836, 849–857. *Z. angew. Chem.*, 1918, 31, Ref., 167–168.

THE metal was rolled at temperatures between 550° C. and 1100° C. in 50° C. steps and then tested in tension and under impact. Three distinct zones of temperature could be distinguished by the resist-

ance to impact, the yield point, and structure, namely above A3, between A3 and A1, and below A1. In iron rolled above A3 marked brittleness is developed depending on the extent of the over-heating. This condition, however, can be entirely removed by subsequent rolling. Between A3 and A1 the resistance to impact increases with the rolling up to a certain critical amount of work, after which it rapidly decreases. Below A1 the impact value falls off steadily as the work put upon the metal increases. At the temperatures of A1 and A3 the material shows a maximum loss of resistance to impact for all degrees of work. As the work is increased on the metal rolled at temperatures above A3 the yield point rises slightly. Between A3 and A1 considerable variations occur; the yield point at first increases rapidly with the degree of work to a "critical" value, after which a sudden fall to a very low figure occurs. Below A1 the yield rises with the degree of work, reaching very high figures. The highest values of the yield point are found at the lower temperatures and fall off quickly to 900° C., the lowest values being found for the pieces rolled at 1100° C. The maximum stress follows unmistakably but less definitely the changes in the yield point and the elongation is, in general, inversely proportional to the yield. The principal changes in structure are a refining of the grain above A3, a crushing of the crystals between A3 and A1, which leads at a critical combination of deformation and temperature to the development of a coarse grain, and below A1 an elongation of the crystals with traces of recrystallisation.

—F. C. Th.

Steel; Gases in alloy — A. Stadeler. Stahl u. Eisen, 1917, 37, 1075—1077. Z. angew. Chem., 1918, 31, Ref., 168.

The gases dissolved in steel consist chiefly of carbon monoxide and hydrogen. Hydrogen predominates at low temperatures, but as the temperature is raised, decreases to a minimum value, after which it again rises with further heating. Carbon monoxide is present only in small quantities at low temperature, but rises on heating to a maximum and then commences to decrease. At high temperatures carbon monoxide and hydrogen are present in more or less equal amounts. Carbon dioxide, methane, and nitrogen do not as a rule constitute more than 5% of the total gases present. The evolution of gases on boring is related to the critical points, the greatest development occurring at these temperatures. In special steels the gases present decrease as the nickel, silicon, chromium, manganese, or other special constituent is present in increasing amounts. The gases dissolved are similar to those present in carbon steels with the exception that silicon and manganese lower the content of carbon monoxide and increase that of hydrogen. Chromium appears to increase the amount of nitrogen present. As in the case of ordinary steels the largest volumes of gas are set free in the region of the critical points.—F. C. Th.

Steel; Influence of titanium on the formation of pearlite in carbon — R. Vogel. Ferrum, 1917, 14, 177—197. Z. angew. Chem., 1918, 31, Ref., 170.

The alloys were prepared from ferrotitanium, it being found impossible to use pure titanium reduced from the oxide. The addition of titanium has no influence on the temperature of the A1 point, but between 1% and 6% Ti this element gives rise to a constituent resembling osmondite. Self-hardening steels never occur in the normal pearlite-free titanium alloys, the suppression of the carbon change arising from the increased inertia and lowered velocity of the pearlite transformation due to the presence of the titanium.

Very slowly cooled titanium steels are hard and withstand heating above the critical point without losing their hardness. When as a result of prolonged heating such steels are rendered pearlitic they are always harder than the plain steel of the same carbon content. Long annealing above the change point and not too slow cooling results in the loss of the hardness. The tensile properties of these steels are related to their content of titanium nitride and carbide, the first being extremely hard and the second very brittle. By melting these alloys in an atmosphere of hydrogen the formation of the nitride at the expense of some of the titanium carbide dissolved in the steel is prevented. The hardness of steels of constant carbon content but of increasing titanium is increased, while at the highest percentage the toughness is somewhat reduced.—F. C. Th.

Electric steel castings. R. F. Flinterman. Amer. Electrochem. Soc., Mar., 1918. [Advance copy.] 9 pages.

GREATER output of steel for castings resulted from replacing the copper spacers between the bus bars of an Heroult furnace by "vulc-asbestos" spacers and insulating the various bus-bar leads from one another by means of mica. The fall in voltage was much reduced due to the reduction of skin effect, and it is suggested that further improvement might be effected by replacing the solid bus construction entirely by flexible cable carried directly through to the electrode clamps, even allowing for induction set up in the steel structure of the furnace.—C. A. K.

Tungsten steel; Structure of — and its change under heat treatment. K. Honda and T. Murakami. Sei. Rep. Tohoku Imp. Univ., 1918, 6, 235—283.

SYSTEMATIC observations have been made of the magnetic properties and microstructure of tungsten steels containing 0.12 to 1.57% C and 0.23 to 30% W. Iron and tungsten form only one compound, Fe_3W , and the tungsten in tungsten steels may be present in this form or as a constituent of tungsten carbide, WC. At the ordinary temperature, iron tungstide is soluble in iron to an extent represented by 9% of tungsten, and in steels which contain larger quantities of tungsten, the tungstide occurs as a separate phase in globular form. Since a portion of the carbon in the steels forms tungsten carbide, the quantity of tungsten required for the appearance of the globules increases with the carbon content. Tungsten carbide combines with cementite to form the double carbide, $4\text{Fe}_3\text{C} \cdot \text{WC}$, with a critical temperature at 400° C. The double carbide dissociates above the Acl point, but recombination of the components occurs during cooling, the final result being an eutectic mixture with ferrite. At high temperatures, tungsten carbide reacts with iron according to the equation, $\text{WC} + 5\text{Fe} = \text{Fe}_3\text{C} + \text{Fe}_3\text{W}$. The resulting lowering of the transformation points increases with the tungsten content and reaches a maximum when this corresponds with the saturated solution of the tungstide in iron. In steels which contain more than 9% W, the lowered Ar1 point is constant at about 410° C, provided the rate of cooling is normal. If a tungsten steel with the lowered Ar1 point is reheated above the Acl point (to about 900° C.) and cooled, the Ar1 transformation takes place at the correct temperature. This is due to the fact that tungsten carbide is formed in accordance with the equation, $\text{Fe}_3\text{C} + \text{Fe}_3\text{W} = \text{WC} + 5\text{Fe}$. The rate of cooling has a marked influence on the transformation points. A large number of photomicrographs and curves accompany the authors' description of their observations and facilitate the interpretation of the somewhat complicated relations.—H. M. D.

Nickel steels; Cause of irreversibility of —. K. Honda and H. Takagi. Sci. Rep. Tohoku Imp. Univ., 1918, 6, 321—340.

THE magnetic behaviour indicates that the irreversibility of nickel steels is to be attributed to the influence of dissolved nickel on the A3 transformation. The irreversibility is not confined to steels containing less than 35% Ni, but probably extends to a nickel content of about 70%. A theoretical explanation of the influence of nickel on the magnetic behaviour of iron is given. The non-expansibility of the alloy containing 35.4% Ni (invar) may be accounted for without assuming the existence of the compound, Fe₃Ni.—H. M. D.

Gas- and water-pipes; Corrosion of — in clay soils containing calcium sulphate. P. Medinger. J. Gasbeleucht., 1918, 61, 73—77, 89—91.

IRON piping, especially cast iron, laid in clay soils containing calcium sulphate and bicarbonate, suffered unusually rapid corrosion, becoming soft and spongy without losing its form or changing its volume. In the case studied most of the pipe had disintegrated, leaving a residue of iron in the metallic condition, graphite, and silicon, phosphorus, and sulphur in oxidised forms. The corrosion is apparently electrolytic, due to local action of iron and graphite couples, although the E.M.F. of this couple (0.6 volt) is much less than the decomposition potential of water. Even 0.1 volt suffices to cause current flow due to diffusion of ions, which prevents the establishment of permanent equilibrium. The concentration of H⁺ ions from the bicarbonate is the deciding factor on the rate of corrosion. The addition of calcium sulphate increases the concentration of H⁺ ions. The clayey character of the soil leads to increased retention of electrolytes which operate as above, and also to the exclusion of oxygen, which retards corrosion by the formation of a protective oxide layer and consequent interruption of current flow. In such soils it is recommended to lay the pipes in a layer of sand or porous earth. Care should be taken that the protective coating of paint, etc., on new pipes is intact, especially at the flanges, which are more liable to abrasion.—H. J. H.

Electric [steel] furnace; The Booth-Hall —. W. K. Booth. Amer. Electrochem. Soc., May, 1918. [Advance copy.] 11 pages.

THE Booth-Hall furnace is of the vertical arc conducting hearth type, an auxiliary electrode acting as a return for the current in the starting operation, to ensure a positive and balanced load. As soon as a pool of molten metal is formed in the hearth, the auxiliary electrode is drawn away and the normal working through the conducting hearth commences. In the two-phase furnace two grids embedded in the hearth and insulated from each other are so related to the main electrodes that the current from the two phases crosses in the bath, ensuring good circulation and mixing of the molten metal. The hearth (either acid or basic) is sintered together in thin layers by using the main electrodes in conjunction with the auxiliary electrode.—C. A. K.

[Electric] furnace; The Vom Baur arc —. J. H. vom Baur. Amer. Electrochem. Soc., May, 1918. [Advance copy.] 7 pages.

IN the design of the Vom Baur solid bottom, poly-phase, arc furnace for melting ferro-alloys or steel (U.S. Pat. 1,252,633; this J., 1918, 156 A), particular stress is placed on the contour of the furnace walls, whereby local destruction of the brick-work is minimised. The central electrode carries

the heaviest current, compensating for the heap of metal naturally piled near the centre during charging, and the smaller electrodes can be tilted to facilitate the melting of this metal heap, or to search for local cold metal. In the normal vertical position of the electrodes the heat at the slag line and also over the entire side walls is uniform. Disturbances of the high power factor, and of the phases and arcs are avoided by keeping all heavy copper conductors well away from the furnace casing and electrode standards.—C. A. K.

Carbon in steel; Rapid determination of —. W. L. Jackson. Met. and Chem. Eng., 1918, 18, 564—565.

A COMBUSTION tube of fused silica is wrapped with resistance wire for a length of 9 in., and packed with quicklime in a steel tube casing. Steel samples are burned in small boats made from nichrome ribbon. Oxygen is admitted so as to allow a maximum of 15 lb. pressure to the train of absorption vessels, the pressure being registered by a mercury gauge. Previous to entering the tube it is washed by means of stick caustic potash, strong caustic potash solution, soda-lime, and calcium chloride contained in four towers of about 7 in. height, the stoppers of which are clamped in. After combustion the gas passes to three sets of zinc-phosphoric anhydride tubes and thence to Johnson absorbing bulbs. Three combustion tubes are used for each furnace—one running, one being weighed, and one in reserve. Results on plain carbon steels check to the third decimal place, and the author has repeatedly made 90 determinations in eight hours.—C. A. K.

Sulphur in iron and steel; Determination of —. H. Pinsl. Chem.-Zeit., 1918, 42, 363—371.

THE hydrogen sulphide evolved when iron is treated with hydrochloric acid may be absorbed in 5% sodium hydroxide solution; the absorption is complete if the alkali solution is contained in a vessel 19 cm. high by 29 mm. wide. The sulphide is then determined by precipitation as cupric sulphide after the alkaline solution has been neutralised, or it may be titrated iodometrically.—W. P. S.

Milling [gold and silver ores] in cyanide solution. A. W. Allen. Met. and Chem. Eng., 1918, 18, 515—519.

ONE of the chief advantages of milling in cyanide solution is the intimate contact resulting between the coarse metal and solvent, though it renders the process of amalgamation only partly effective. Only 90—95% of the gold is usually recoverable by cyaniding, whereas if the gold is amenable to amalgamation, practically 100% can be recovered. The fact that all the gold is soluble in cyanide is reaffirmed, but loss is occasioned, amongst other reasons, by the absorption of metal-bearing solution by colloid particles. Pyritic ores may be roasted, with recovery of sulphur, and the gold is then released in a form suitable for extraction. The acidity of ores having an acid reaction should be neutralised before cyaniding to avoid the loss of hydrocyanic acid. By milling in cyanide solution the possibility of mechanical loss is augmented as the quantity of metal-bearing solution is increased and for the same reason the cost of precipitation is higher. The process is specially applicable when there is no advantage in a preliminary alkaline treatment of the ore, when amalgamation would result in no appreciable saving, or when adequate dewatering prior to cyaniding is impracticable.—C. A. K.

Copper; Influence of lead on molten — containing gases. W. Stahl. Metall u. Erz, 1917, 14, 365—366. Z. angew. Chem., 1918, 31, Ref., 155.

LEAD when present in copper melts, influences the duration of the reactions and removes absorbed sulphur dioxide, hydrogen, and carbon monoxide, thus rendering the metal dense and preventing it from rising. The reduction of the cuprous oxide by lead, $2\text{Cu}_2\text{O} + 2\text{Pb} = 4\text{Cu} + 2\text{PbO}$, prevents the reaction, $2\text{Cu}_2\text{O} + \text{Cu}_2\text{S} = 6\text{Cu} + \text{SO}_2$, from occurring. In the temperature range $550^\circ\text{--}900^\circ\text{C.}$, and with high pressure of sulphur dioxide—up to 850 mm. of mercury—lead also reacts with sulphur dioxide according to the equations:

At lower pressures of sulphur dioxide and higher temperatures these reactions are reversed. At 1300°C. and low pressure—the conditions of the molten copper bath—lead does not react with sulphur dioxide by itself, but the reaction $2\text{Pb} + 2\text{Cu} + \text{SO}_2 = 2\text{PbO} + \text{Cu}_2\text{S}$ takes place.—F. C. Th.

Copper cyanide plating bath; Experiments with the —. F. C. Mathers. Amer. Electrochem. Soc., May, 1918. [Advance copy.] 6 pages.

THE solution recommended is copper cyanide 4.5% (6 oz. per gallon), sodium cyanide 4.3 to 4.7% (5.7 to 6.3 oz.), sodium carbonate 4% (5.3 oz.). This bath, which is more concentrated than that usually employed, gave approximately 100% yields at both electrodes unless the operating conditions were severe or too much cyanide was present, when the cathode yields tended to become lower. The bath can be worked at 6 to 9 amps. per sq. ft. Much better cathode yields were obtained when the baths were operated at 80°C. than at the ordinary temperature. Using the stronger solution recommended, a thicker deposit can be obtained without bad edges as well as higher cathode yields than with weaker solutions. Very little free cyanide is required. Sodium carbonate is of advantage, as is also probably sodium sulphate. Sodium hydroxide should not be added.—F. C. Th.

Copper; Effect of iron sulphate in the electrolytic precipitation of — from sulphate solution with insoluble lead anodes. E. F. Kern. Amer. Electrochem. Soc., May, 1918. [Advance copy.] 11 pages.

THE presence of iron lowers the efficiency of the electrolytic precipitation of copper from sulphate solutions when insoluble lead anodes are used, the loss of efficiency increasing with the quantity of iron present. This effect also increases as the amount of copper decreases, hence the efficiency decreases progressively during the electrolysis. The lowering of efficiency is due to the oxidation of ferrous sulphate to the ferric state at the anode and the reduction of ferric sulphate at the cathode. When iron is present a higher current efficiency is obtained by working with a lower current density at the cathode than at the anode. A smoother and purer deposit was obtained at 50°C. than at lower temperatures. Iron in solution renders the deposit less smooth and less dense, and reduces the voltage required for the electrolysis from 2 to approximately 1.8 volts.—F. C. Th.

Zinc ores; Anthracite as a reducing agent for —. O. Mühlbauer. Metall u. Erz, 1918, 15, 162—165.

ANTHRACITE is considered to be specially suitable for the reduction of zinc ores. It gives a high yield of a very porous coke, and coking occurs at

a lower temperature than in the case of bituminous coals, and there is no risk of dilution of the zinc vapour by large volumes of volatile products. The use of anthracite in the muffle increases the yield of metal, since a greater charge of ore may be introduced into a furnace of given capacity. By sifting out the finest portions, which are high in ash, from the anthracite, the value of the fuel is increased and the resistance to the circulation of the gases is diminished.—F. C. Th.

Brass furnace; A rocking electric —. H. W. Gillett and A. E. Rhoads. Met. and Chem. Eng., 1918, 18, 583—590.

A NEW type of arc furnace, developed as the result of investigation by the U.S. Bureau of Mines, consists of a drum, 5 ft. long and 5 ft. in diameter, lined to a depth of 12 in. and having a capacity of about 1300 lb. per 2 hrs. The drum is mounted to rotate about an axis slightly inclined to the horizontal, has a charging opening and pouring spout at the top, and is provided at each end with a water-cooled, graphite electrode, 4 in. in diameter, the latter being threaded for continuous feed and adjusted by hand. Single-phase, 60-cycle current, stepped down to 120—130 volts, is used, with an external reactance to stabilise the arc. The current varies between 1000 and 2000 amp. (averaging about 1650), the open circuit voltage being about 106—116 under load; and the power input is varied by altering the length of the arc. By means of an adjustable control device, the furnace is rocked automatically, a complete oscillation of a "safe rock" (80°) and a "full rock" (200°) occupying $1\frac{1}{2}$ and $3\frac{1}{2}$ seconds, respectively. The rocking angle is increased from 80° , when the charge begins to melt, to 200° , when melting is complete; at full rock the metal washes the whole circumference of the hearth except for the portions adjoining the charging door. In a continuous run extending over four days, during which over 34 short tons of metal was melted, the power consumption averaged 257 kilowatt-hours per ton charged. The cost of melting was found to be much less in the rocking electric furnace than in coke-fired furnaces. On the basis of a 10-hour day, the total cost by the former method was about one-half of that for crucibles alone by the latter (at present prices); and the amount of metal saved amounted to twice the cost of the coke consumed in the crucible process.—W. E. F. P.

Aluminium; Metallography of —. Recrystallisation and grain growth. R. J. Anderson. Faraday Soc., July 23, 1918. (Advance proof.) 5 pages.

THE first effect produced by annealing cold-worked aluminium is a small increase in hardness, further heating resulting in a softening. There may be a drop in the scleroscope hardness before microscopically visible internal changes occur. The temperature of most rapid grain growth resulting from the annealing of the cold-worked metal is a function of the deformation, being quite definite for a definite amount of cold work. Samples of aluminium hot rolled at 455°C. showed no grain growth when annealed up to 425°C. , and recrystallisation was incomplete. The scleroscope hardness was, however, only 5, i.e., mechanically full softening had occurred. At 485°C. full recrystallisation had taken place, accompanied by some grain growth. The time of the annealing is of importance since 10 mins. at 595°C. did not produce complete recrystallisation, although 60 mins. at 540°C. had done so. The more highly strained material is more readily recrystallised than less severely deformed metal, both as regards time and temperature. The results indicate that aluminium follows the same annealing laws as do other metals.

—F. C. Th.

Aluminium sheet; Annealing and recrystallisation of cold-rolled — R. J. Anderson. *Met. and Chem. Eng.*, 1918, 18, 523–527.

ANNEALING of cold-rolled aluminium sheet is usually carried out at a temperature of 375° C. for a period of 18–30 hours, and gives a maximum softness from the standpoint of mill operation corresponding to a hardness number of 4 to 5 as tested by the Shore scleroscope. If annealed for say 30 hours at 400° C., the scleroscope hardness will be about 4, but the sheet will be in a weakened condition and show a relatively large grain size, whereas if the period of annealing is only 10 mins., the grain size will be smaller, and the hardness still about the same figure. The occurrence of blistering during annealing is uncertain, but probably depends on the speed of pouring and the content of gases of the original cast metal. Long period annealings are harmful, giving a poor drawing quality and large grain size, and the common practice of exposing sheets for say 24 hours at 375° C. is unnecessary, as adequate softening can be effected by a short exposure at this temperature. (See also this J., 1918, 245 A.)—C. A. K.

Aluminium; Influence of iron, tungsten, and nickel upon the resistance of — to acids. Von Zeerleder. *Metall u. Erz.* 1917, 14, 325–330. *Z. angew. Chem.*, 1918, 31, Ref., 166.

THE addition of iron in all concentrations exerted a harmful influence. The resistance to sea water of a 10% iron alloy was only $\frac{1}{4}$ that of pure aluminium. The addition of 1.5% W to the iron-aluminium alloy improves it slightly. The mechanical properties were also better, the brittle alloy being rendered tough and malleable. A partial substitution of nickel or cobalt for the iron renders the resistance to acids still worse.

—F. C. Th.

Tin; Electrolytic refining of — E. F. Kern. *Amer. Electrochem. Soc.*, May, 1918. [Advance copy.] 12 pages.

THE effect of the addition of aloin, gelatin, pectone, quinoline, oil of cloves, and boric acid to the electrolyte was to restrain the formation of non-adherent deposits. The best deposits were obtained from a solution containing 5 grms. of tin as stannous fluosilicate and 7.5 grms. of hydrofluosilicic acid per 100 c.c., with 1 gm. of aloin in 500 c.c. Aloin was a suitable addition agent only in the case of stannous fluosilicate electrolyte. Hydrofluoric acid to the extent of 60% of the total acid content is not detrimental. The best current density for the solution recommended was 24 amps. per sq. ft. of cathode, with a voltage of 0.4 volt.

—F. C. Th.

Zinc [in alloys]; Gravimetric and volumetric determination of — as zinc mercury thiocyanate. C. S. Jamieson. *J. Amer. Chem. Soc.*, 1918, 40, 1931–1939.

LUNDELL and Bee's method of estimating zinc in alloys as zinc mercury thiocyanate (*Trans. Amer. Inst. Met.*, 1914, 116) is criticised. The factor for obtaining the weight of zinc should be 0.1315, not 0.1266, since the precipitate has the composition $\text{ZnHg}(\text{SCN})_2$, after being dried at 102°–108° C. Excellent results are obtained by using ammonium thiocyanate instead of the potassium salt. Cadmium, cobalt, copper, bismuth, manganese, and mercurous compounds should be absent. Nickel in small amounts does not interfere appreciably. Ferric compounds in appreciable quantities should be reduced by sulphur dioxide. Arsenious compounds need not be removed. Instead of weighing the zinc mercury thiocyanate the following volumetric method, based on the equation: $\text{ZnHg}(\text{SCN})_2 + 6\text{KIO}_3 + 12\text{HCl} = \text{ZnSO}_4 + \text{HgSO}_4 + 2\text{H}_2\text{SO}_4 + 4\text{HCN} + 6\text{KCl} + 6\text{KCl} + 2\text{H}_2\text{O}$, gives trustworthy results. The zinc mercury thiocyanate corresponding with 0.03–0.10 gm. of zinc is precipitated and washed, the filter containing the precipitate is transferred to an 8-oz. (titration bottle), a thoroughly cooled mixture of 35 c.c. of concentrated hydrochloric acid and 10 c.c. of water, followed by 7–8 c.c. of chloroform, is added, and a solution of potassium iodate (19.644 grms. in 1000 c.c. 1 c.c.=0.00100 gm. of zinc) is at once added rapidly while the bottle is well shaken. When the iodine liberated in the first stage of the reaction has disappeared, the titration is continued slowly, the closed bottle being thoroughly shaken after each addition until the iodine colour has disappeared from the chloroform indicator, which marks the end-point. If more than 50 c.c. of the iodate solution is required, a further 10–15 c.c. of concentrated hydrochloric acid must be added in order to prevent hydrolysis of the iodine monochloride. (See also *J. Chem. Soc.*, Sept., 1918.)—C. S.

metric method, based on the equation: $\text{ZnHg}(\text{SCN})_2 + 6\text{KIO}_3 + 12\text{HCl} = \text{ZnSO}_4 + \text{HgSO}_4 + 2\text{H}_2\text{SO}_4 + 4\text{HCN} + 6\text{KCl} + 6\text{KCl} + 2\text{H}_2\text{O}$, gives trustworthy results. The zinc mercury thiocyanate corresponding with 0.03–0.10 gm. of zinc is precipitated and washed, the filter containing the precipitate is transferred to an 8-oz. (titration bottle), a thoroughly cooled mixture of 35 c.c. of concentrated hydrochloric acid and 10 c.c. of water, followed by 7–8 c.c. of chloroform, is added, and a solution of potassium iodate (19.644 grms. in 1000 c.c. 1 c.c.=0.00100 gm. of zinc) is at once added rapidly while the bottle is well shaken. When the iodine liberated in the first stage of the reaction has disappeared, the titration is continued slowly, the closed bottle being thoroughly shaken after each addition until the iodine colour has disappeared from the chloroform indicator, which marks the end-point. If more than 50 c.c. of the iodate solution is required, a further 10–15 c.c. of concentrated hydrochloric acid must be added in order to prevent hydrolysis of the iodine monochloride. (See also *J. Chem. Soc.*, Sept., 1918.)—C. S.

Alloys; Thermo-electromotive force of some — M. A. Hunter and J. W. Bacon. *Amer. Electrochem. Soc.*, May, 1918. [Advance copy.] 14 pages. (See also this J., 1918, 32 A.)

OF the base-metal thermo-couples now on the market the most widely used are iron-constantan and nickel-aluminium-nickel chromium. The former is satisfactory below 1000° C., the chief cause of its failure being the rapid oxidation of the iron. The E.M.F. of the couple is high and varies almost as a straight-line function of the temperature. It also maintains its calibration well. The latter couple may possibly be used up to 1400° C., but the E.M.F.-temperature curve is not so good nor is the original calibration so well maintained. Copper-nickel-chromium alloys are suggested for thermo-couple elements. The E.M.F.-temperature curves are approximately straight lines; the materials have high melting points and resist oxidation well, and large variations in composition have little effect on the E.M.F. The best combination among those tried was Cu 50: Ni 50: Cr 20, or Cu 50: Ni 50: Cr 10, combined with Ni 100: Cr 10.—F. C. Th.

[Metals;] New thermo-electric effect [in —]. C. Benedicks. *Rev. Mét.*, 1918, 15, 320–332.

IN a homogeneous metallic circuit an asymmetrical temperature distribution produces an electromotive force (this J., 1917, 36). If, for instance, two fine platinum wires are laid upon each other in the form of a cross, and an end of each connected to a galvanometer, deflections corresponding to a millivolt are obtainable by slightly heating one arm. If the area of contact of the wires is increased by pressure, so that the temperature difference between the two arms is lowered by conduction, the E.M.F. is also lowered. The effect with a ferro-silicon containing 50% Si is much greater than with platinum. With a tungsten wire of 0.22 mm. diameter an E.M.F. of 19 millivolts was obtained when one arm of the cross was heated to 900° C. Surface oxidation, especially in the cases of tantalum and iron, results in perturbations. Errors in thermo-couples etc. arising from this cause may be eliminated by producing by pressure etc. efficient contact between the wires.—F. C. Th.

[Ore] concentrates; Approximate determination of the minerals in —. K. Thomas and F. W. Apgar. *Met. and Chem. Eng.*, 1918, 18, 514.

MICROSCOPIC examination of the concentrates and tailings from mill practice gives a simpler and more rapid indication of the quantitative mineral

composition than a complete chemical analysis. A sample is spread out evenly on a microscopic slide and the number of grains of each or of similar constituents in the field of vision is counted, at the same time noting the average size of grain for each. A percentage volume analysis is then readily obtained if the grains are of even size, otherwise a simple correction to allow for the difference in grain size is applied. The percentage by weight is obtained by multiplying by the specific gravity. The important minerals are easily distinguished under the microscope by colour and surface appearance, and if a large number of the grains are complex the desirability of finer grinding is indicated.—C. A. K.

Molybdenite; Identification of —. F. C. Fuchs. Eng. and Min. J., 1918, 105, 991.

A LITTLE of the mineral suspected to contain molybdenite is added to molten caustic potash. Within 5 mins., if molybdenite be present, swelling takes place, then rapid solution, and the production of an intense yellowish-red colour. When cool, if a few drops of water be added to the fusion, followed by drops of hydrochloric acid, the colour changes, and spots of blue, green, yellow, and red appear. It is suggested that molybdenite (MoS_2) yields one atom of S to the molten potash with the formation of a red double sulphide. The method can be utilised for the rapid solution of molybdenite for purposes of analysis.—C. A. K.

PATENTS.

[Steel] alloy. J. Churchward, Lakeville, Conn. U.S. Pats. (A) 1,261,742 and (B) 1,261,743, Apr. 2, 1917. (Appl. No. 15,116 of 1917.)

A STEEL alloy containing Ni about 1–5%, Mo about 0.25–3%, Mn under 0.70%, and (A) V about 0.15–0.50%, or (B) Ti from a trace to about 0.50%.

—T. H. B.

Annealing high speed steel; Process of —. F. Bagliardi, Milan. Eng. Pat. 116,829, Oct. 18, 1917. (Appl. No. 15,116 of 1917.)

HIGH speed steel is heated to incipient redness (500° – 550° C.), placed under a heap of cinders until it assumes a blue-black colour, and then immersed in water or greasy substances, preferably a paste consisting of 20% of soft animal grease which does not contain stearine, 70% of tallow, and 10% of wood charcoal.—C. A. K.

Rust-preventing process. D. Reichenstein, Zürich. Eng. Pat. 103,474, Nov. 14, 1916. (Appl. No. 16,309 of 1916.) Under Int. Conv., Feb. 3, 1916.

IRON surfaces (e.g., of steam turbines and boilers) exposed to the action of steam and air are protected from rusting by the addition of ammonia or other volatile base to the feed water or to the mixture of steam and air in the apparatus. Alternatively the volatile base may be formed in the boiler by reaction between a salt of the base and a stronger base.—C. A. K.

Cast iron; Method of producing —. F. A. Hirz, Struthütten. Ger. Pat. 303,657, Sept. 5, 1916.

IRON and steel scrap are melted together with a slag in a cupola. Certain impurities, such as oxygen compounds and sulphur, pass from the iron into the slag, whilst manganese, silicon, etc., pass from the slag into the iron. By regulating the character of the slag the purification may be carried to any desired extent.—F. C. Th.

Iron ores, furnace dust, etc.; Process for briquetting —. W. Mathesius, Nicolassée. Ger. Pat. 304,820, Oct. 27, 1915. Addition to Ger. Pat. 300,461.

THE components required for the preparation of the highly basic binding agent, rich in iron oxide, described in the chief patent, are obtained from the ore to be briquetted. For example, in the case of ores containing insufficient of the basic calcium compounds, part of the iron oxide is removed by magnetic separation and the residue is calcined. The friable ore may, as an alternative, be separated into a number of portions of different chemical composition, one or more of which may be used as binding material. The ore may be broken up by first calcining it and then quenching it, after which magnetic separation may be effected.

—F. C. Th.

Ferro-phosphorus; Process of making —. *Process of producing iron phosphide from iron phosphatic material.* H. A. Webster, Columbia, Tenn., Assignor to J. J. Gray, jun., Rockdale, Tenn. U.S. Pats. (A) 1,264,236 and (B) 1,264,237, Apr. 30, 1918. Date of appl., Oct. 13, 1916.

(A) A CHARGE consisting essentially of a fluxing material, carbon, and iron phosphate is heated in a closed furnace to a temperature sufficient to cause the oxygen in the phosphate to combine with the carbon, while maintaining the partial pressures of the reaction products above the normal. Ferro-phosphorus containing more than 22% of phosphorus is obtained. (B) A mixture of phosphatic material, a fluxing agent, and carbon in excess is heated in a rotary furnace. Iron-bearing material may be added to combine with elemental phosphorus to prevent its loss in the exit gases.—C. A. K.

Ferro-silicon; Process for the manufacture of —. T. A. F. Holmgren, Stockholm, J. O. Aqvist, and G. Hellsing, Trollhättan, Sweden. Ger. Pat. 303,480, Oct. 26, 1916. Under Int. Conv., Oct. 29, 1915.

At a very high temperature in the electric furnace carbon will reduce quartz and clay. The quartz is the more easily reduced, a very high temperature and prolonged period being required for the preparation of aluminium. By working under conditions such that the quartz is practically completely reduced while the alumina remains untouched, and in the presence of iron, ferro-silicon is produced. The iron may be produced simultaneously by the reduction of iron pyrites.

—F. C. Th.

Crucible and like furnaces; Means for preheating the charge in — J. Gaunt, D. Brookfield, and J. Tylor and Sons, Ltd., London. Eng. Pat. 115,222, Apr. 30, 1917. (Appl. No. 5095 of 1918.)

THE cover of a crucible furnace of the type described in Eng. Pat. 114,684 (this J., 1918, 308 A) carries a hopper lined with refractory material, and this lining extends downwards to form part of the lining of the cover and is preferably curved so that the gases arising from the furnace chamber will be deflected and caused to come into intimate contact with the charge in the hopper. The cover is mounted in such a way that it can be raised and swung clear of the body of the furnace.

Copper alloys; Process of making — H. Eldridge, New York. Eng. Pat. 115,917, June 4, 1917. (Appl. No. 8000 of 1917.)

SEE U.S. Pat. 1,216,571 of 1917; this J., 1918, 62 A. The copper is heated to a temperature below its melting point and is subjected, in the solid condition, to the vapour of the alloying metal, the more fusible alloy melting and running off, thus exposing new surfaces of the copper.

Alloy. C. Vickers, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,264,459, Apr. 30, 1918. Date of appl., Sep. 27, 1916.

IN an alloy of copper, aluminium, and iron, the aluminium constitutes not less than 7% nor more than 12%, and the iron not less than 3% nor more than 5% (preferably 3–4%) of the whole, the proportion of the aluminium to the iron being not more than $2\frac{1}{2}$ to 1.—T. H. B.

Metals such as tin and zinc; Method and apparatus for oxidising or volatilising — H. Macdonochie, London, and D. de Ros, Greenhithe. Eng. Pat. 115,870, Apr. 23, 1917. (Appl. No. 5694 of 1917.)

THE flame from a burner supplied with liquid or gaseous fuel is caused to heat the bottom of a hearth containing a charge of metal, and is then directed down on to the charge and heated air is caused to mingle with the fume given off from the metal, in a chamber connected to the hearth chamber. There are four horizontal, superposed and interconnected chambers, the lowermost being the primary combustion chamber, the chamber next above serving to heat the bottom of the third chamber, which is provided with a hearth for the metal and a deflector for directing the flame on to the charge, whilst the fourth chamber serves for conducting away and over the hearth the gases, products of combustion, fume, etc. The third chamber is so constructed as to allow of the removal and replacement of the hearth. The fourth chamber is provided with air-heating conduits having openings for the admission of some of the heated air to the chamber to oxidise the fume from the hearth. —T. H. B.

Tin and lead fumes; Method for removing — from smelter gases. H. Hocking and E. Apor, Budapest. Ger. Pat. 303,764, July 28, 1914.

THE gas is drawn or forced through a washing chamber divided by partitions into a series of smaller spaces. The high velocity of the gas produces in the liquid a copious foam which retains the particles of dust.—F. C. Th.

Nickel-copper matte; Process for refining — G. T. Holloway, London. Eng. Pat. 116,139, May 30, 1917. (Appl. No. 7742 of 1917.)

UNROASTED nickel-copper matte is alloyed with blister or crude copper, preferably containing nickel,

so as to obtain a product of sufficiently low sulphur content, and is then cast into anodes for electrolytic refining. Metals of the platinum group are said to be more readily recovered when an excess of copper over nickel is present.—C. A. K.

Nitre cake; Utilisation of — [for treatment of copper ores]. W. H. Hyatt, Long Ditton, Surrey, and E. N. Fellowes, London. Eng. Pat. 116,181, July 6, 1917. (Appl. No. 9803 of 1917.)

A SUITABLE copper ore, e.g. a carbonate ore containing about 5% of copper carbonate, is added to about its own bulk of a solution of nitre cake containing three parts by weight of water to one of nitre cake. The mixture is heated at about 100°C. until all the copper is dissolved. The copper is subsequently recovered from the solution by the usual methods, and the sodium salts by evaporation and recrystallisation, or the solution may be neutralised with a suitable carbonate, e.g., chalk, sodium carbonate, or, preferably, ammonium carbonate, and used as an insecticide.—L. A. C.

Ore separating machines. Fraser and Chalmers, Ltd., London, and W. Bullock, Bexley, Kent. Eng. Pat. 116,228, Dec. 29, 1917. (Appl. No. 19,235 of 1917.)

THE material to be separated falls from a hopper down a vertical or inclined air space of annular form separating a wheel, possessing magnetic permeability, from the pole-faces of an electromagnet. The non-magnetic particles fall freely through the air space, while the magnetic portion is carried on the wheel beyond the field produced by the polar surfaces. The wheel is preferably formed as the frustum of a cone revolving between similarly inclined pole-faces, whereby the air space may be suitably adjusted by raising or lowering the wheel, the periphery of which may be serrated.—C. A. K.

[*Ore*] *roasting furnaces.* F. Rowley and A. M. M. Merton, London. Eng. Pat. 116,235, Jan. 10, 1918. (Appl. No. 588 of 1918.)

IN a multiple-shaft roasting furnace having a number of superimposed hearths, the ore is spirally rabbled by means of rotating shafts arranged in pairs, the rabblers attached to the first shaft moving the material spirally outwards and those on the second shaft spirally inwards before the ore is dropped on to a lower hearth on which a similar motion is produced. A separate charging hole is provided for each pair of shafts and the various pairs are spaced so far apart that the material in its progress through the furnace is rabbled by only one pair of shafts and to all intent is roasted in a separate two-shaft furnace. The roaster gases however travel over the hearths of a series of the two-shaft furnaces, thus making the apparatus a multiple furnace in regard to the heating. —C. A. K.

Roasting furnace. A. Zavelberg, Hohenlohehütte. Ger. Pat. 303,543, July 8, 1916.

THE volume of the space over the roasting hearth is reduced by building a second arch of brickwork below and independent of the original arch of the furnace. The air supplied is brought into closer contact with the hearth.—H. J. H.

Zinc; Process for the production of — O. Baltin, Lipine, Germany. U.S. Pat. 1,261,342, Apr. 2, 1918. Date of appl., Feb. 25, 1914.

NAPHTHALENE is added to a mixture of the zinc ore and reducing agent, and the whole briquetted. —T. H. B.

Zinc; Method of recovering — from waste solutions containing zinc and sodium sulphates. O. Bimpage, Duisburg. Ger. Pat. 304,937, Jan. 14, 1917.

A PORTION of the solution which has been treated with quicklime, and then separated from the insoluble calcium sulphate, is used as a precipitant. The caustic soda is converted into sodium sulphate and hydrated zinc oxide precipitated. The addition of quicklime to this sodium sulphate solution regenerates caustic soda which may be used again. —F. C. Th.

Tungsten or molybdenum articles; Process of coating — with precious metals. F. A. Fahrenwald, Cleveland, Ohio, dedicated to the Government and people of the United States. U.S. Pat. 1,261,110, Apr. 2, 1918. Date of appl., May 31, 1916. (Dedicated to the public.)

ARTICLES of ductile tungsten or molybdenum are immersed in a bath of a fused oxygen salt of an alkali metal and then in a bath of molten gold at not more than 1350° C. for half a minute. The articles thus coated with gold are then ready for soldering or brazing. A coating of silver, platinum, or palladium instead of gold, or of an alloy of any of these metals, may be used. —J. H. J.

Tungsten; Method of preparing alloys of — with precious metals. G. Fuchs, Berlin. Ger. Pat. 304,551, Feb. 29, 1916.

ONE at least of the metals to be alloyed is first prepared as a basis alloy with nickel, iron, or aluminium. A gold alloy containing 75 parts of gold to 10–15 of tungsten and 10–15 parts of nickel, may be used in jewellery as a substitute for platinum. It can be cast, hammered, and rolled and takes a much finer polish than platinum does. An alloy of 80 parts of fine silver, 10–15 of nickel, and 10–15 parts of tungsten possesses a higher specific gravity and greater strength than the gold alloy. It is much less affected by atmospheric oxidation than silver and takes a better polish. These alloys may also find technical application on account of their resistance to acid attack. —F. C. Th.

Metals [tungsten]; Extraction of — from their ores. E. M. Hamilton, Assignor to Hamilton, Beauchamp, Woodworth, Inc., San Francisco, Cal. U.S. Pat. 1,261,383, Apr. 2, 1918. Date of appl., Mar. 14, 1917.

ORE or concentrate containing tungsten is reduced to a suitable condition of fineness, and mixed with water and an alkali carbonate or bicarbonate to form a pulp, the ratio of solution to ore being approximately between 1:1 and 2:1. The pulp is heated under pressure, then filtered, and tungstic acid is separated from the solution by addition of an acid. An excess of alkali carbonate or bicarbonate is used, but not sufficient to cause appreciable solution of silica. —T. H. B.

[Ore] concentration process. W. A. Scott, Chicago, Ill. U.S. Pat. 1,261,303, Apr. 2, 1918. Date of appl., Aug. 27, 1917.

A MIXTURE of an inert gas, such as air, with a permanent bubble-modifying gas, *e.g.*, methane, coal gas, acetylene, etc., is introduced into a body of ore pulp, preferably through a porous medium. A column of bubbles is formed above the normal level of the ore pulp, and the effect of the bubble-modifying gas is to cause certain of the mineral constituents to adhere to the bubbles. Good results have been obtained in the concentration of the zinc ore of Butte, Montana, by using acetylene as bubble-modifying gas.

Sulphide ores; Method of treating —. F. K. Cameron and J. A. Cullen, Salt Lake City, Utah, and R. W. Hyde, New York, Assignors to American Smelting and Refining Co., Salt Lake City. U.S. Pat. 1,261,694, Apr. 2, 1918. Date of appl., June 18, 1917.

SULPHIDE ore is added to boiling sulphuric acid of at least 50° B. (sp. gr. 1.53), elemental sulphur being distilled off and metal values recovered from the residue. —W. E. F. P.

Silicious ores; Method of treating —. G. H. Wigton, Eureka, Utah. U.S. Pat. 1,264,586, Apr. 30, 1918. Date of appl., Sept. 22, 1916.

FINELY-GROUND silicious ores with a base metal content insufficient to form a slag at the volatilising temperature of the metallic compound, are mixed with an excess of alkali or alkaline-earth chloride, and the metallic chloride separated by distillation. The metallic chloride is subsequently reduced to the metallic state, the chlorine being recovered in the slag which may be used in the treatment of a fresh charge of ore. —C. A. K.

Metals from ores and other materials; Distilling process for recovering —. Process for recovering mercury. C. H. Fulton, St. Louis, Mo., Assignor to Metallurgical Laboratories, Inc., Chicago, Ill. U.S. Pats. (A) 1,264,628 and (B) 1,264,629, Apr. 30, 1918. Date of appl., Apr. 21, 1917.

(A) ORES or other metal-bearing materials are formed into briquettes with or without reducing materials and suitable binders and are distilled in an electrical resistance furnace, the blocks themselves constituting the resistors. It is necessary that the briquettes should not appreciably alter their shape or volume during the distillation. (B) The process described under (A) is applied to mercury ores. —C. A. K.

[Ore] reduction apparatus. P. J. MacDonald, Los Angeles, Assignor to C. L. Claffin, jun., Bakersfield, Cal. U.S. Pat. 1,264,832, Apr. 30, 1918. Date of appl., Sep. 18, 1916.

MEANS are provided for delivering oxide ore into a reduction chamber and agitating the uppermost stratum of the ore with a reducing agent, the under portion being relatively at rest. Heat is applied and the waste gases are carried away through a separate outlet. —C. A. K.

Metal scrap and ores; Apparatus for treatment of — with acids. H. Stegmeyer, Charlottenburg. Ger. Pat. 303,475, Mar. 5, 1914.

THE acid liquor and the metal or ore are conveyed along one or more troughs to which a reciprocating motion is applied. The trough communicates with the liquor reservoir through a valve which is operated by the pulsations and so causes a circulation of acid. The latter can be arranged to flow in the same direction as the material or in counter current as desired. —H. J. H.

Sintering fine and powdery material; Process for —. W. Schumacher, Berlin. Ger. Pat. 303,799, Nov. 4, 1916.

FINE ore or flue-dust is mixed with fuel and subjected in a vertical furnace to a blast of strongly heated air, such as the hot blast of a blast-furnace. —F. C. Th.

Briquetting fine ores; Process for —. Brück, Kretschel, and Co. Osnabrück. Ger. Pat. 304,484, Feb. 27, 1915.

SLAKED lime and the dust from a blast furnace smelting hematite ores are added to the ore as a binding agent and the mixture is compressed, and treated with steam. Very good briquettes can be made from 84% of concentrates, 12% of hematite fine dust, and 4% of slaked lime.—F. C. Th.

Aluminium; Process for the preparation of — suitable for the decoration of melts of iron and steel. Rombacher Hüttenwerke A.-G., I. Bronn, and W. Schemmann, Rombach. Ger. Pat. 304,645, July 6, 1917.

THE aluminium is melted in a crucible and granulated by pouring into flowing water. This carries it along into a collecting chamber from which it is removed and placed on the pan-shaped cover of the melting furnace and quickly dried by the waste heat of the furnace.—F. C. Th.

Phosphoric slags; Process for the production of high-percentage — of high solubility in citric acid in the basic open-hearth process. B. Queling, Saarbrücken. Ger. Pat. 304,894, Feb. 20, 1917. Addition to Ger. Pat. 301,839.

THE dephosphorising period is divided into one or more stages after each of which the slag is transferred to a special slag furnace. This eliminates the possibility of the reduction of phosphorus from the slag and its re-absorption by the metal during recarburisation.—F. C. Th.

Phosphoric slags; Method for obtaining highly — in the manufacture of ingot-iron or steel from sulphurous pig iron. B. Queling, Saarbrücken. Ger. Pat. 304,895, Feb. 7, 1917. Addition to Ger. Pat. 301,839.

TO the bath of metal in the mixer briquettes of burnt lime, manganese oxide, and carbon are added. The solubility of sulphur in pig iron is lessened by a high carbon content, while that of the slag is increased. The presence of the manganese oxide accelerates the desulphurisation. (See also Ger. Pats. 302,283 and 304,894; this J., 1918, 377 A, and preceding.)—F. C. Th.

Tin-plates or sheets and other like metal coated plates or sheets; Appliances used in the manufacture of —. D. Davies, Llanelly, and D. Jones, Glamorgan. Eng. Pat. 116,250, May 2, 1917. (Appl. No. 6501 of 1918.)

Wrought-iron; Manufacture of —. J. Aston, Assignor to A. M. Byers Co., Pittsburgh, Pa. Reissue 14,457, Apr. 2, 1918, of U.S. Pat. 1,255,499, Feb. 5, 1918. Date of appl., Feb. 19, 1918.

SEE this J., 1918, 212 A.

Electrode as used for welding purposes. M. M. Irvine, Glasgow. U.S. Pat. 1,261,395, Apr. 2, 1918. Date of appl., Sept. 17, 1917.

SEE Eng. Pat. 108,759 of 1916; this J., 1917, 1100.

Metal articles; Sealing and annealing of —. F. Perry, Assignor to Metalloids, Ltd., Tipton. U.S. Pat. 1,261,606, Apr. 2, 1918. Date of appl., Feb. 15, 1917.

SEE Eng. Pat. 102,660 of 1916; this J., 1917, 143.

Scotch hearth; Mechanically-operated —. A. S. Moses, New York, Assignor to St. Louis Smelting and Refining Co., St. Louis, Mo. U.S. Pat. 1,263,695, Apr. 23, 1918. Date of appl., Apr. 3, 1916.

SEE Eng. Pat. 103,205 of 1916; this J., 1917, 294.

Slags; Generation of steam from the heat contained in —. C. Vautin, London. U.S. Pat. 1,264,229, Apr. 30, 1918. Date of appl., Oct. 24, 1914.

PATENTS.

Furnaces; Electrically heated resistance —. H. A. Greaves and H. Etchells, Sheffield. Eng. Pat. 115,866, Apr. 11, 1917. (Appl. No. 5072 of 1917.)

THE furnace is so constructed that leakage currents may be usefully employed to produce uniform heating, the crucible chamber to be heated being built of refractory material, which is a poor electrical conductor when hot, *e.g.*, silica ware. The ducts surrounding the chamber are filled with an electrical resistor of granular form, and the partitions which separate the ducts are made of refractory materials, which are fairly good second class electrical conductors when hot, *e.g.*, chromite, magnesite, silundum. The electrical current is supplied at the free end of each duct by separate electrode pole-pieces directly connected to the feeding conductors, the ducts being in the form of continuous loops which unite in a common chamber under the crucible chamber. Leakage currents pass from each heating unit through the partitions to the units on either side.—B. N.

Electrical contacts; Method of making —. G. A. Rignon, Genoa, Italy. U.S. Pat. 1,264,685, Apr. 30, 1918. Date of appl., Sept. 30, 1916.

CONTACTS of tungsten, molybdenum, or a metal of the iron group, of an exceedingly high welding point, for use in contact breakers in magnetos employed for the ignition of explosive mixtures in internal combustion engines, are made by uniting the metal to its support by electro-thermal welding at a very high temperature, then coating the support and its contact with good conducting metal, such as copper or silver, with the exception of the two faces between which the break takes place, in order to reduce the resistance.—B. N.

Carbon electrodes; Manufacture of —. B. E. D. Kilburn, London. From Det Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank, Christiania. Eng. Pat. 116,853, Jan. 9, 1918. (Appl. No. 551 of 1918.)

ELECTRODES are manufactured in continuous lengths, in the furnace in which they are used, by feeding a suitable carbonaceous mixture into a mould leading to the furnace, the mixture being preferably rammed round a metallic core. In the case of a vertical electrode, the lower end is rapidly heated by the arc or melting crater, while the upper portion is baked partly by the heat of the furnace and partly by the heat generated by the current passing through the metallic core. As the electrode burns away fresh portions of the mixture are added in the mould and the electrode pushed down. The upper portion of the electrode may be heated more gradually by an independent circuit, the main current only traversing the harder baked section.

Spraying electrode for the electrical purification of air or gases containing dust or fog. Metallbank und Metallurgische Ges. A.-G., Frankfurt. Ger. Pat. 305,363, May 23, 1914.

AN electrode for discharging a fine spray of sparks in all directions consists of a vessel charged with water and made of porous material or of perforated metal provided with a mantle of porous material. The vessel or its mantle may, for instance, be made of earthenware or porcelain or other mineral substance, which is either used in the crude condition and maintained in the desired shape, or has been subjected to treatment which does not destroy its porosity. The liquid may be drawn into the electrode from a suitable vessel by the capillary action of the electrode itself or its mantle.

XII.—FATS; OILS; WAXES.

Fatty oils; Process for deodorising —. W. P. Schuck. Met. and Chem. Eng., 1918, 18, 608—609.

DEODORISATION of any oil or fat is effected by blowing hydrogen or a gas containing hydrogen as its main constituent through the heated oil, in a vessel from which atmospheric oxygen is excluded. In the commercial application of the process the volatile fatty acids, etc., are condensed, and washed from the hydrogen, which is then dried and used again. No hardening of the oil takes place, since the treatment is effected in the absence of a catalyst. In comparative tests in which an oil was treated in this way with pure hydrogen and pure nitrogen, and the fumes condensed, it was found that the total iodine value of the condensed liquid and of the residual oil was lower when hydrogen than when nitrogen had been used. In the nitrogen experiments the oils had a burnt taste, and in some cases had only been partially deodorised, whilst they contained about three times as much free fatty acids as the oils which had been treated with hydrogen. When a current of hydrogen is made to bubble through a heated oil the free fatty acids begin to be removed at about 210° C., and in most cases are reduced to within 0.15% in 20 mins. at 275° C. Coconut oil containing over 14% of free fatty acids had the amount reduced to 0.12%, whilst fish oil with over 5.14% yielded a product containing only 0.14% of free fatty acids, the loss on purification being only 1.1% more than was attributable to the removal of the acids. The condensed fatty acids are available for the manufacture of soap. Oils thus deodorised keep sound very much longer than oils deodorised by steam-treatment. For example, coconut oil deodorised as described was pleasant to the taste after four months' exposure in a loosely covered tin, whilst the same oil deodorised by steam had become rancid in a few weeks under the same conditions. It is suggested that this process may be used for the purification of oils which have been burnt in cooking and of garbage fats, and that it will be of value for deodorising castor oil and removing the free fatty acids, without interfering with its medicinal properties. (See also U.S. Pat. 1,260,072 of 1918; this J., 1918, 312 A.)—C. A. M.

Linseed oil; Study of the oxidation of —. I. G. E. Holden and L. G. Radcliffe. J. Soc. Dyers and Col., 1918, 34, 138—146.

WEIGHED quantities (about 1 grm.) of linseed oil were placed on pieces of cotton cloth, about 3 in. square, previously freed from mineral matter and fat; these were introduced into a series of three or four connected gas wash-bottles and a slow current of air was drawn through the series of bottles. It was found that the linseed oil in the first bottle of a series dried more rapidly than that in the second, whilst the second was more rapid than the third, and so on; but that on continuing the current of air for periods ranging from 450 to 500 hours the units of each series showed equal increments in weight (17 to 18%). On heating the bottles containing the dried samples for definite periods at 100° C., this original gain was reduced to a gain of only 1.0 to 3.5%. In further experiments in which quantities of 0.1 to 0.125 grm. of linseed oil were spread on roughened glass plates and exposed to definite temperatures, it was found that the velocity of drying increased with the temperature, but that the higher the temperature the lower the maximum increase in weight, and the less the accelerating influence of any driers present on the drying of the oil. When dried at or just below 34° C. linseed oil gains from 17 to 18% in weight,

whereas when dried at 100° C., the maximum increase is much less (e.g., 7.8%), and at 150° C., no increase in weight is observed, probably owing to accelerated formation and evolution of volatile products. An equal drying capacity is shown by the linoleate or resinates of the same metal containing the same proportion of that metal, but manganese has six times the efficiency of lead as a drier. The rate of drying of linseed oil is slightly increased by the presence of turpentine. Linseed oils which dry most slowly will be found to contain a higher proportion of non-drying substances than do rapidly drying oils. Oils with low iodine values require a longer time to dry than those with higher iodine values. On treating dried linseed oil films with ether, the amount of organic matter removed from films dried at 100° C. is much less than from films dried at 15° C., and a higher proportion is extracted from films from oils having the lower iodine values. These results indicate that the saturated glycerides have an important influence on the rate of drying of the oils, and the ultimate decomposition of a film of linseed oil appears to be due to the decomposition and emanation of the non-drying substances in the film. The greater durability of a linseed oil film which has been dried at a high temperature must be attributed to the more rapid volatilisation of the non-drying substances by the heat prior to the formation of the linoleyn. Drying of an oil is accelerated by the action of ultra-violet rays, so much so that linseed oil by itself under these conditions dries as rapidly as an oil containing a drier in solution. Volatile products from linseed oil oxidised in a current of air at 100° C. gave the reactions of unsaturated aldehydes and contained drops of an oily substance consisting of traces of free fatty acids in admixture with saponifiable matter. The non-drying constituents of the linseed oil undoubtedly affect the degree of hardness of the oxidation product. They are decomposed under the influence of ultra-violet rays, as is shown by the fact that linseed oil attains only 12 to 13% increase in weight, as compared with 17 to 18% under normal conditions of light (see also this J., 1914, 266).—C. A. M.

Oil in seeds: Determination of — W. B. Gray. J. S. African Assoc. Anal. Chemists, 1918, 1, 5-7.

For extraction of the oil from oil seeds Krenssler's apparatus is more satisfactory for use with ether than Soxhlet's apparatus, only a few c.c. of the solvent in excess of that needed to saturate the sample being required. Small seeds can be completely extracted in about 2½ hours, whilst palm kernels, copra, etc., require 8 hours. In the case of coarsely ground material the sample should first be extracted for 4 hours, then ground in a mortar, and the extraction continued for a further 4 hours. Thorough drying of the seeds before extraction is essential to prevent extraction of gum resins from the husks. In the case of drying oils the residue left on evaporating the extract should be dried in a current of dry hydrogen, coal gas, or carbon dioxide.—C. A. M.

Oiticica oil—a new drying oil. E. R. Bolton and C. Revis. Analyst, 1918, 43, 251-254.

The kernels of seeds known in Brazil as *oitica* or *oilzika*, and probably derived from *Conepia grandifolia* (*Rosaera*) yielded 62% of an oil which was semi-solid at the ordinary temperature, but at higher temperatures consisted of a solid fat in a liquid medium. The oil had the following characters:—M. pt., incipient fusion, 21.5° C.; complete fusion, 65.1° C.; sp. gr. at 15.5°/15.5° C., 0.9694; free fatty acids as oleic, 5.7%; unsaponif. matter,

0.91%; saponif. value, 188.6; and iodine value, 179.5; m. pt. of fatty acids, 53.7°; solidif. pt. of fatty acids, 67.0° C. When brominated the oil yielded only traces of insoluble bromides, but, on standing for 2 to 3 days, the solution became deep brown and a pale liquid separated. When heated to 250° to 270° C. in an atmosphere of carbon dioxide no solidification took place, whereas tung oil became solid under the same conditions, but at 300° C. polymerisation occurred, with the formation of a stiff, clear, transparent jelly, which when mixed with an oil, such as linseed oil, or a solvent, such as chloroform, swelled up and became gelatinous. The jelly formed by tung oil on polymerisation is turbid. When heated in a thin film at 100° C. the new oil gained in weight 4% (tung oil 2 to 3%), and the oxidised skin was practically insoluble in petroleum spirit, chloroform, or acetone. A solution of the oil in commercial benzene when allowed to dry on glass formed a more uniform and transparent skin than did tung oil. The lead soap was more granular than that of tung oil and was soluble in small quantities in linseed oil. The oil will probably be suitable for the manufacture of linoleum as well as for varnish.

—C. A. M.

Sanga-sanga (Ricinodendron africanum); Chemical study of the nuts of — Pieracrt. Ann. du Musée colon. de Marseille, 1917, 5, 27-37. Bull. Agric. Intell., 1918, 9, 456.

THE nuts of *Ricinodendron africanum*, a large tree growing in the French Congo and other countries of West Equatorial Africa, are of about the size of a hazel nut. Unsorted nuts yielded 28% of kernels, which contained 17.64% of water and 55.29% of a pale yellow oil with the following characters:—Sp. gr. 15°/15° C., 0.9345; ref. index at 19.5° C., 1.5028; acid value, 0.86; saponif. value, 194.4; Hehner value, 98.85; and m.pt. 32.3° to 34.5° C. The oil contained 9.77% of glycerol, and yielded no bromides insoluble in ether. When shaken with a saturated solution of iodine in chloroform it set to a gelatinous mass. "Sanga-sanga" oil dries more rapidly than linseed oil, and could be used for waterproofing, for canking ships' hulls, and as mortar or lamp oil. The oil-cake is rich in nitrogen and phosphates, and if proved to be free from toxic substances would be an excellent feeding-stuff.

—C. A. M.

Fats from Rhus laurina and R. diversiloba. J. P. McNair. Bot. Gaz., 1917, 64, 330-336.

FATS isolated from *Rhus laurina* and *R. diversiloba* had the following constants respectively:—Sp. gr. (18.5° C.) 0.8987, 0.9872; solubility 136, 170 mgrms. per litre in 95% alcohol at 20° C.; iodine value (Hübl) 11.44, 8.79; saponif. value, 157.1, 220.6; m.pt., 74°, 53° C. The substances appear to be more similar to Japan wax than to any other fat. A decrease in the poisonous properties of the fruit of *R. diversiloba* occurs simultaneously with an increase in the fat content, but this does not appear to be due to the conversion of the poison into fat.

Grease from waste materials: Recovery of — by the solvent extraction process. J. H. Garner and J. F. Carmichael. J. Soc. Dyers and Col., 1918, 34, 113-122.

THE recovery of grease and fatty acids from the effluents of wool scouring is capable of very profitable extension. After precipitation by nitre cake the magma is pressed in one of two ways: either in the so-called oven press after being wrapped in sacking by hand, or in a steam-heated filter-press into which the previously heated magma is forced by steam pressure or compressed air. The cake

from the former retains 12–15% of moisture and that from the latter up to 35%, and the dry substance from both still contains 20–30% of grease which should be recovered by extraction with solvents. Moreover the dry sewage sludge of industrial towns contains 15–40% of grease, the lower value representing purely domestic sewage and the lowest limit of profitable recovery treatment. Sludges containing over 30% of fat on the dry substance are best treated in two stages, viz.: by hot pressing for the direct recovery of grease, and subsequent extraction of the cakes by solvents, whereas those containing less than 30% should be pressed for the removal of water only and treated directly with solvents. In either case, the sludge must not be precipitated by lime but only by acids. For profitable treatment with solvents, the moisture in the cake must be reduced to 15–20%, preferably in mechanical drying apparatus heated by means of waste heat. The Ruggles-Coles dryer consists of two inclined concentric cylinders arranged so that flue gases pass downwards through the central cylinder and back up through the annular space between the two, while the disintegrated cake passes down the annular space. The Dublin dryer consists of a series of shelves around a vertical shaft, every alternate shelf being attached to the shaft; a series of rakes and scrapers on the lower sides of the shelves pushes the material from one shelf to the other against an ascending current of hot air. The B.T.W. dryer consists of two inclined rotary steel cylinders placed one above the other in a brick flue; the material passes down the upper one in which it is broken up and rubbed by means of scrapers and teeth and passes into the lower one in which it is tossed about by lifting vanes and dried. The solvent extraction plant consists of extraction vessel, still, and condenser. The material is charged into the extraction vessel on a canvas filter bed supported by perforated plates. The depth of material charged depends on its physical condition and its freedom from a tendency to sink together and clog. An open material with 45–55% of mineral matter may be packed to a depth of 8–9 ft., whereas one containing only 25% of mineral matter and a large amount of organic matter may only be worked with a depth of 4–5 ft. Solvent (petroleum spirit) is admitted to the space below the grid and gently boiled so that the vapour passes upwards and saturates the material with hot solvent. A continuous percolation of dissolved grease thus takes place into the space below the grid and the process is continued for 6–10 hours until the material is exhausted. The grease solution is then blown into the still and the solvent left in the material is recovered by steaming. A copper tubular counter-current condenser gives the best results; failing that, a multitubular cast-iron condenser; the ordinary steel coil condenser does not last, owing to the corrosive action of the volatile fatty acids. The grease is refined by boiling with dilute sulphuric acid, stirring for 20 mins., and allowing to settle for 24–48 hours. The loss of solvent amounts to 3–45 galls. per ton of material treated. The exhausted material contains 4–5% of fat and about 10% of moisture and is in a suitable condition for use as a fertiliser. The cost of the process depends very largely on the richness of the material worked; figures are given based on 15% of recovered grease, showing a cost of £9 15s. per ton of grease.—J. F. B.

Sulphonated oils: Analysis of — G. W. Schultz. J. Amer. Leather Chem. Assoc., 1918, 13, 190–192.

THE method of R. Hart (this J., 1917, 1139) has been modified in some particulars, and results obtained by it compared with those given by the

method of the American Leather Chemists' Association Committee. The acid value of the fatty acids of the oil before sulphonation cannot be used in calculating total fat, as the sulphonation lowers the acid value of the acids. Unsaponifiable matter is determined after the saponification value. The solution is made alkaline and diluted so as to contain about 50% of alcohol, boiled for a few minutes, and subsequently extracted with petroleum spirit. The extracted soap solution from the determination of unsaponifiable matter is carefully boiled to dryness, the residue dissolved in water, and the solution boiled to expel alcohol. The fatty acids are then precipitated and extracted by means of ether, the ether solution washed with concentrated sodium sulphate solution, and the ether distilled off. The saponification value of the fatty acids is then determined (not the acid value, on account of lactones and anhydrides). If the oil contains ammonia, the free fatty acids cannot be determined as usual. The following method is given: 10 grms. of oil is dissolved in 95% alcohol and titrated with sodium hydroxide in presence of phenolphthalein; the solution is boiled for $\frac{1}{2}$ hr. to expel ammonia, cooled, again neutralised with standard alkali, and the process repeated until no more ammonia is expelled by boiling. The solution is then diluted with water and titrated with sulphuric acid, using methyl orange as indicator, to determine alkali present as soap. The following calculation gives the neutral fat: subtract the ammonia content (expressed as mgrms. of potash per gm. of oil) from the saponification value of the sample, and further deduct the free fatty acids and acids present as soap (again expressed in mgrm. potash), and divide the result by the saponification value of the fatty acids. The result multiplied by 100 is the percentage of neutral fat. Analyses show that the neutral fat determined as above is much higher than the amount found by the Committee method; nevertheless the author considers the figures reliable.—F. C. T.

Catalysers for reduction or hydrogenation purposes; Method of producing — and apparatus therefor. Soc. de Stéarinerie et Savonnerie de Lyon, and P. Berthon, Lyons, France. Eng. Pat. 107,004, May 19, 1917. (Appl. No. 7259 of 1917.) Under Int. Conv., May 19, 1916.

CATALYSTS such as finely divided reduced nickel, cobalt, manganese, copper, etc., for hydrogenation processes or for the reduction of organic substances and fatty bodies, are prepared by reducing the metallic oxides at about 250° C. in a neutral liquid medium. The medium may be a hydrocarbon obtained from solid paraffin, vaseline, heavy petroleum oil, etc., which is not susceptible of hydrolysis or saponification, with the addition of 0.25 to 0.5% of stearic acid. The material is placed in vertical tubes mounted in a cylindrical casing, and superheated steam is circulated round the tubes to maintain them at about 250° C. The metallic oxide is then added and a strong current of hydrogen injected into the space below the lower tube-plate through a perforated diaphragm to distribute the gas into the tubes. Finely perforated plates are also arranged in the tubes. Very finely divided metal is obtained after about 2.5–3 hours and the liquid medium is separated by centrifuging. The catalyst is obtained in the form of cakes containing a high proportion of metal.—W. F. F.

Oil or the like; Presses for expressing —. A. W. French, Piqua, Ohio. U.S.A. Eng. Pat. 107,200, June 11, 1917. (Appl. No. 8347 of 1917.) Under Int. Conv., June 10, 1916.

The press-plates are composed of a supporting plate and a mat plate provided with the necessary perforations and channels. The under sides of the plates have dependent projecting bars, whilst there are upward projecting guides on the edges of the mat plates, so arranged as to "telescope" into the dependent bars of the plate immediately above, when the plates are brought together. The upward bars also serve as guides in inserting the bag containing the meal.—C. A. M.

Animal and vegetable oils, fats, and greases; Treatment of —. C. F. Paul, jun., Newark, N.J., Assignor to The Spalding By-Products Co., New Haven, Conn. U.S. Pat. 1,264,206, Apr. 30, 1918. Date of appl., May 17, 1916. Renewed Dec. 13, 1917.

GREASE is forced, together with an aqueous solution of an alkali peroxide, through a narrow orifice, or is otherwise emulsified with the alkali, while a jet of air under pressure is directed upon the material as it leaves the orifice, or air is blown into the mixture to effect fine subdivision. The mixture is then treated with sulphuric or other acid to form the sulphate or other water-soluble salt of the alkali, and the grease is separated from the aqueous solution of such salt.—C. A. M.

Surgical dressing [from beeswax]. Product of beeswax and process of manufacturing the same. K. J. Holliday, Glen Osborne Borough, Pa., Assignor to Holliday Chemical Co., Pittsburgh, Pa. U.S. Pats. (A) 1,264,185 and (B) 1,264,186, Apr. 30, 1918. Dates of appl., (A) Sept. 25, and (B) Sept. 26, 1917.

(A) The surgical dressing consists of a composition of paraffin and the esters and hydrocarbons of beeswax, and a gum of the "elimi" group, in the proportions 95 to 65% of paraffin, 5 to 35% of beeswax, and 0.1 to 5% of gum, having a definite melting point from 120° to 140° F. (50° to 60° C.). The material is substantially free from all free acids, and is capable when melted of forming an elastic, non-cracking, and non-irritating covering. (B) A neutral product free from acids and containing the neutral esters and hydrocarbons of beeswax, is prepared by mixing melted beeswax with an alkaline solution to form an emulsion, and separating the soaps and waxes from the emulsion whilst in a heated state. The soaps are then eliminated from the product, which is non-irritating to the flesh, and non-corrosive when in contact with metals.—B. N.

Dispersoids [emulsions, etc.]; Process for stabilising —. L. Sarason, Charlottenburg. Ger. Pat. 302,093, Apr. 29, 1915.

DISPERSOIDS which do not form hydrosols may be rendered stable by the use of nucleic acid solution (e.g., yeast nucleic acid) as a protective colloid. Examples are given of the formation of emulsions of linseed oil with glycerin and pressed yeast, and of a powder colour with pressed yeast, warmed to liquefaction. It is preferable to add a preservative such as formaldehyde.—B. V. S.

Emulsions of organic chlorides containing more than one carbon atom; Process of preparing —. Chem. Fabrik Stockhausen und Co. Ger. Pat. 304,909, Oct. 9, 1907.

CHLORINE compounds containing more than one carbon atom, such as tetrachloroethane, trichloro-

ethylene, etc., are emulsified by means of compounds containing a sulpho group, such as sulphonated oils and fats, sulphonated fatty acids, especially Turkey-red oil, or the gelatinous soaps prepared from sulphonated castor or other oils (Ger. Pat. 113,433; see Eng. Pats. 2596 of 1896 and 24,868 of 1897; this J., 1896, 363; 1898, 162).

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Conifer resin. C. G. Schwalbe and W. Schulz. Z. angew. Chem., 1918, 31, 125—127.

SEASONING renders the resin in pine wood insoluble to a great extent, and the longer a wood is kept, particularly in the form of sawdust, the smaller is the quantity of resin which can be extracted even by a series of different solvents used successively. This fact explains the varying quantities of fat recorded as being present in the resin.

Whiting; Process of making a substitute for —. H. B. Kipper, Solvay, N.Y. U.S. Pat. 1,264,092, Apr. 23, 1918. Date of appl., Apr. 30, 1915.

A FILLER of the character of whiting is prepared by incorporating with a finely divided inorganic earthy material, e.g. calcium carbonate, a small percentage of salt of a higher fatty acid, such as oleic acid.

—E. W. L.

Carbon or lampblack [from natural gas]; Manufacture of —. L. E. Hirt, Charleston, W. Va. U.S. Pat. 1,264,796, Apr. 30, 1918. Date of appl. July 21, 1915.

THE character of carbon black derived from natural gas depends upon the proportion of oil vapour in the gas. To obtain uniform products the oil content of the gas is reduced below a predetermined minimum, e.g. by treatment with cold oil. After the treatment with cold oil, the gas may be intimately mixed with oil at a higher temperature so as to restore to it a definite quantity of oil vapour, which may be in excess of that removed.—C. A. M.

Lute. C. E. Ferris, Eaton Rapids, Mich. U.S. Pat. 1,263,398, Apr. 23, 1918. Date of appl., Jan. 25, 1918.

Phenolic condensation product varnish; Art of preparing and handling —. L. V. Redman, Evansston, and A. J. Weith and F. P. Brock, Assignors to Redmanol Chemical Products Co., Chicago, Ill. U.S. Pat. 1,261,615, Apr. 2, 1918. Date of appl., May 8, 1917.

A VARNISH is prepared in the form of two solutions which are kept in separate containers until just before use. One portion consists of a solution of a soluble condensation product of a phenolic substance and a methylene compound containing such excess of the former as to be incapable of yielding a final insoluble product, e.g., 1½ phenolic group to each methylene group. The second portion is a solution of a quantity of an active methylene compound sufficient to combine with the soluble phenolic condensation product and yield a varnish. —C. A. M.

Resins; Manufacture of —. F. W. Sperr, jun., Oakmont, and M. Darrin, Wilkinsburg, Pa., Assignors to H. Koppers Co., Pittsburgh, Pa. U.S. Pat. 1,263,813, Apr. 23, 1918. Date of appl., Dec. 7, 1917.

RESINS are manufactured from compounds of the coumarone-indene group by subjecting such compounds to heat and a pressure of 50–300 lb. per sq. in.; or by subjecting a solution of such compounds to heat and pressure, then distilling, and blowing a gaseous fluid through the heated residue. —E. W. L.

Resins, oleo-resins, oils, and turpentine; Process of extracting — from resinous woods. D. J. Ogilvy, Cincinnati, Ohio. U.S. Pat. 1,264,551, Apr. 30, 1918. Date of appl., Sept. 10, 1912.

FINELY divided resinous wood is boiled with a mixture of water and a volatile solvent for resins and oils, and the mass of resinous and oily constituents which separates is distilled to separate the lighter turpentine and oils from the heavier oils and resins. The amount of volatile solvent used for the extraction should be greater than the proportion of natural solvent in the wood.—C. A. M.

Rubber; Method of vulcanising —. W. P. Payne, New Haven, Conn., Assignor to L. Candee and Co. U.S. Pat. 1,263,462, Apr. 23, 1918. Date of appl., Sep. 10, 1915.

RUBBER and leather are united by assembling the constituent parts in such a way that the pores of the leather will afford passages for the escape of vapours and gases generated in the rubber during vulcanisation, then subjecting the rubber side to a fluid pressure, exerting a suction on the leather side, and heating the whole at a vulcanising temperature for the time necessary to effect vulcanisation.—E. W. L.

Rubber waste; Process of reclaiming —. F. L. Kryder, Akron, Ohio, and E. W. Snyder, Indianapolis, Ind. U.S. Pat. 1,263,567, Apr. 23, 1918. Date of appl., Jan. 4, 1918.

RUBBER waste is heated with a mixture of aniline oil, 10; rubber resin, 10; a mineral hydrocarbon, 2; and carbolic acid, 1 part, under pressure, and a further mixture of acetic acid, 5; turpentine, 1; and naphtha, 3 parts is introduced, the pressure being thereby increased without substantial increase of temperature; the reclaimed rubber is separated from the liquid mass.—E. W. L.

Rubber coagulum or similar material and processes for preparation of the same for vulcanisation. W. J. Mellersh-Jackson, London. From General Rubber Co., New York. Eng. Pat. 116,323, June 1, 1917. (Appl. No. 7887 of 1917.)

SEE U.S. Pat. 1,259,794 of 1918; this J., 1918, 313 A.

Rubber coagula or similar materials and process for the preparation of the same from latex for vulcanisation. W. J. Mellersh-Jackson, London. From General Rubber Co., New York. Eng. Pat. 116,325, June 1, 1917. (Appl. No. 7905 of 1917.)

SEE U.S. Pat. 1,259,793 of 1918; this J., 1918, 313 A.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning; Theory of —. A reply. J. A. Wilson. J. Amer. Leather Chem. Assoc., 1918, 13, 177–189. (See this J., 1918, 313–314A.)

LYOTROPE influence is apparently related to the hydration of ions, but its mechanism is not understood. It cannot therefore be used to explain the phenomena of the swelling of gelatin in acids. Objection is also taken to Bennett's statement that the adsorption law rests upon as secure a foundation as the theory of ionisation. The work of Gibbs applies only to true solutions. The chief authorities regard the electrical charges of colloidal particles as due to chemical combination, and Zsigmondy gives equations for the action of acids and alkalis on proteins identical with those proposed by Procter and Wilson. On the assumption that gelatin and hydrochloric acid combine to form a highly ionisable salt, equations can be derived with which the experimental results agree exactly. The fact that an empirical adsorption formula can be found to fit the results shows that such adsorption is really chemical combination. Bennett's views on chrome tanning are vitiated by the fact that colloidal chromic oxide is positively charged, whereas his theory requires a negative charge.—F. C. T.

Chrome [tanning] liquors; Acidity of —. A. W. Thomas and M. E. Baldwin. J. Amer. Leather Chem. Assoc., 1918, 13, 192–203.

DETERMINATIONS of the acidity of a chrome liquor and a chromium sulphate solution were made by means of the hydrogen electrode. On dilution, while the basicity (i.e., the ratio of chromium to SO_4 combined with chromium) remains constant, the acidity diminishes, though not so rapidly as the concentration of the solution. For instance, in the original liquor the concentration of hydrogen ion was 0.0049 mol. per litre; when this liquor was diluted to 20 times its volume the concentration immediately fell to 0.0008 and diminished further during 7 days to 0.00055. Equilibrium is attained most rapidly with the most dilute solutions. When the original liquor was diluted to 800 times its volume, equilibrium was reached immediately. The addition of acid or alkali to a chrome liquor causes an immediate rise or fall in the concentration of hydrogen ions, after which equilibrium is attained slowly by a considerable diminution or increase according to whether acid or alkali has been added. The basicity alters according to the amount of added acid or alkali.—F. C. T.

Hide and pelt; Biological and chemical constituents of —. Elastins in the tanning process. W. Moeller. Collegium, 1918, 105–117, and 125–137.

THE elastin content of the hide depends largely on the feeding and age of the animals. Elastin is more or less completely desulphurised by means of alkali, but is only dissolved by boiling water under pressure. It differs from collagen in yielding tyrosine among its decomposition products, in being more resistant to the action of acids and alkalis, and in being attacked by trypsin. The preliminary processes aim at overcoming as far as possible the indifference of the elastin and making it more like collagen in its behaviour towards tannins. Trypsin digests elastins, hence bating removes them from the hide. Experiments show that the decomposition products of the elastins are particularly suitable for destroying the compounds of lime with collagen. Together with this action, the removal of the elastic fibres results in a complete change in the structure of the hide. The falling of hides and skins is due to the peptising action of the decomposition products of elastin on the lime compounds, and not to the removal of the lime or elastin.—F. C. T.

PATENTS.

Leather; Process for drying japanned or "patent" —. C. Heyl, Worms, Germany. Eng. Pat. 113,622, Feb. 21, 1918. (Appl. No. 3143 of 1918.) Under Int. Conv., Apr. 27, 1916.

JAPANNED or patent leather is dried under the action of ultra-violet rays in the presence of vapours of ammonia derivatives (hydrazine), or nitrogen, or other inert gases, the drying process being much more rapid than when ammoniacal vapours are used.—C. A. M.

Leather; Process for drying japanned or patent —. C. Heyl, Worms, Germany. Eng. Pat. 112,460, Jan. 2, 1918. (Appl. No. 148 of 1918.) Under Int. Conv., Nov. 14, 1916.

IN the drying of patent leather by means of ultra-violet rays the formation of ozone, which is deleterious, is avoided by filtering off all rays of wavelength greater than 200μ , or else a source of light is used which does not emit such rays. Suitable filters are calc spar, "uvioi glass," water, or aqueous solutions, whilst arc lamps with long drawn arcs may be used without filters.—F. C. T.

Hides and skins; Treatment of — prior to and during tanning. L. A. Groth, Purley, Surrey. Eng. Pat. 116,334, June 4, 1917. (Appl. No. 7979 of 1917.)

HIDES or skins are suspended in tanks containing the solutions used in leather manufacture, and are kept in horizontal reversing motion by means of electric power. At the same time an electric current is passed through the liquors and hides in order to accelerate and perfect the various processes. The system is said to effect great saving in time and cost of production.—F. C. T.

XVI.—SOILS; FERTILISERS.

Soil acidity. 1. Its relation to the growth of plants. E. Truog. Soil Sci., 1918, 5, 169–195.

THE first of a series of papers on soil acidity, in which a general discussion of the literature on the subject is given. The conclusions of the author are that the amount of lime which should be applied to a soil depends upon three factors:—the lime requirement of the crop or crops to be grown, the degree of acidity of the soil, and the fertility of the soil. The lime requirement of a plant refers to the actual lime needs of the plant itself, especially as to the ease and rate at which lime must be secured from the soil by the plant for normal growth. This is dependent on the lime content and the rate of growth of the plant and the feeding power of the plant for lime as governed by the extent and character of its root system, the internal acidity of the roots, and their excretion of carbon dioxide.

—W. G.

Soil acidity as influenced by green manures. J. W. White. J. Agric. Res., 1918, 13, 171–197.

EXPERIMENTS were undertaken to determine the cause of the production of acidity in soils continuously manured with ammonium sulphate. Portions of the acid soil were taken and finely divided young green plants, of leguminous and non-leguminous varieties usually ploughed in for green manure, mixed with them and the mixture maintained at a constant moisture content for nine months. During the first two weeks the lime requirement of the mixture decreased nearly one half, although no change took place in the control portion of soil alone. Thereafter there was an increase in the lime requirement until it exceeded that of the soil alone. Nitrates increased continuously during the period and the amount became twice as much as that in the soil alone, although the latter amount had doubled during the period. The nitrification was insufficient to account for the increased lime requirement. A similar series of experiments was carried out with the same plants first air-dried before being used. The results were similar, although the changes occurred more slowly. Analyses were made to determine the effect of the green manuring on the organic matter in the soil. In every case the amount was larger at the end of

the period than that in the soil alone. Three-fifths of the added organic matter was destroyed during the period; of that left, one-third was present as humus soluble in dilute alkali. The air-dried plants were not so largely decomposed as those applied green.—J. H. J.

Soil solution in different classes of soil; Relation between biological activities in the presence of various salts and the concentration of the —. C. E. Millar. J. Agric. Res., 1918, 13, 213—223.

A SANDY loam and a clay loam soil respectively were mixed with 2% of dried blood, and varying amounts, 0.001—0.7%, of magnesium sulphate, calcium nitrate, calcium chloride, and potassium chloride were added in solution. The depression of the freezing point was determined, and after incubation for 4 days at 30° C. the amount of ammonia produced. It was found that with the larger amounts of the salts, ammonification fell off. In the sandy loam there was a point in the concentration of the salt where this reduction was marked, namely, 0.064% with magnesium sulphate, calcium chloride, and potassium chloride, and 0.2% with calcium nitrate. The increase in osmotic pressure calculated from the lowering of the freezing point, occurred at concentrations of 0.016% and 0.032% respectively. With the clay loam, no point of marked depression of ammonification occurred except with potassium chloride. Thus the effect of salts on ammonification is modified by the nature of the soil. Dried blood alone causes an increase in osmotic pressure varying with the soil used.

—J. H. J.

Nitrogenous constituents of soil; Effect of heat on some —. R. S. Potter and R. S. Snyder. Soil Sci., 1918, 5, 197—212.

THREE silt loams and a peat soil were examined, and the heat treatment consisted of two hours at 100° C., dry heat, 2 hours at 200° C., dry heat, 3 hours in an autoclave at 10 lb. per sq. in. pressure on each of three successive days, or 3 hours in an autoclave at 15 lb. per sq. in. once, followed in each case by inoculation with fresh soil emulsion and incubation for 10 or 20 weeks. A blank series without inoculation was also carried out. The amount of ammonia in the soil was increased by all the heat treatments alone, greater increases being, in general, obtained at the higher temperatures. In the case of the peat soil heated at 200° C., however, there was excessive volatilisation of ammonia. The amino-acid nitrogen results followed those for ammonia, but the peat soil was again an exception, there being very little change by any of the treatments. Dry heat at 100° C. caused very little change in the nitrate content of the soil, but the steam heat in the autoclave in each case caused a considerable increase in the nitrate content of all the soils. At 200° C. dry heat there was almost total disappearance of nitrates. In every case there was an increase in the soluble non-protein nitrogen, the lowest results being obtained with the peat soil. In the three loam soils the subsequent incubation for ten hours after dry heat at 100° and 200° C. caused an increase in ammonia, but in one of these cases the 20 hours' incubation caused a decrease. Incubation had very little effect on the ammonia content of the treated peat soil. Ten weeks' incubation in all cases caused a drop in the amino-acid nitrogen, the value rising again, however, during the next ten weeks. Nitrates were increased during both periods of incubation. In the peat soil there was always a decrease in the soluble non-protein nitrogen after incubation, but in the mineral soils there was an increase due to incubation after dry heat at 200° C.

—W. G.

Peat soils; Determination of lime and phosphoric acid in —. Comparison of the Jönköping with the Bremen method. C. O. Rost and F. C. Clapp. Soil Sci., 1918, 5, 213—218.

IN the Bremen method the soil sample is incinerated, the ash extracted with *aqua regia*, and the lime and phosphoric acid in the extract determined by the usual methods. In the Jönköping method a quantity of air-dried soil equivalent to 70 grms. of water-free material is digested with 700 c.c. of 12% hydrochloric acid for 48 hours. Higher results are obtained for iron and aluminum oxides, lime, and phosphoric acid by the Bremen than by the Jönköping method. This lower value for lime in the second method is due to a portion of the extracted lime being rendered insoluble in water during the course of the analysis and hence not included in the final precipitation. This loss varies with the amount of iron present.—W. G.

Soil organisms; Correlation between the production of carbon dioxide and the accumulation of ammonia by —. J. R. Neller. Soil Sci., 1918, 5, 225—241.

A STUDY of the decomposition of organic matter in soils by pure cultures or by mixtures of pure cultures of micro-organisms. Over a 12-day period the production of carbon dioxide was more uniform than the accumulation of ammonia; but, in general, a high production of carbon dioxide by pure cultures of bacteria was accompanied by a high ammonia accumulation with 1% of cottonseed meal or of alfalfa in sandy loam. Pure cultures of fungi caused more oxidation of carbon but much less accumulation of ammonia than the bacteria. Soil infusions resembled the fungi cultures with respect to ammonia accumulation but were more active in production of carbon dioxide. Mixtures of pure cultures of bacteria showed no antagonism, but in some cases a symbiotic relation seemed to exist.—W. G.

Sulphur phosphate composts; Experiments with — conducted under field conditions. J. G. Lipman and H. C. McLean. Soil Sci., 1918, 5, 243—250.

EXPERIMENTS designed to determine the best conditions of preparing sulphur and "floats" (rock phosphate) soil composts for rendering available the phosphorus of "floats," showed that temperature is an important factor in sulphur oxidation and hence in formation of available phosphorus, and consequently for maximum efficiency composts should be made up in warm weather.—W. G.

PATENTS.

Fertiliser. J. N. Hoff, New York. U.S. Pat. 1,261,025, Apr. 2, 1918. Date of appl., Sep. 29, 1917.

HUMUS is digested with phosphate rock and acid phosphate (superphosphate) in order to produce reverted phosphate and to render the nitrogen of the humus more available. The mass is neutralised and digested again. It is then inoculated with bacteria and dried till the moisture is reduced below 30%, whereby many of the bacteria are converted into the spore state. The mass is again inoculated with suitable bacteria.—J. H. J.

Fertiliser; Process of making a mixed potash, nitrogenous, and phosphatic —. Process for producing a mixed potash and nitrogen fertiliser. R. F. Gardiner, Clarendon, Va. U.S. Pats. (A) 1,261,116 and (B) 1,261,117, Apr. 2, 1918. Date of appl., Aug. 6, 1917.

(A) Rock phosphate, pebble phosphate, apatite, alunite, muscovite, orthoclase, and leucite are

ground separately so as to pass a sieve with 136 meshes to the inch, and are then mixed. Ammonium sulphate is added to the mixture which is heated below 150° C. and then up to 400° C. until the gaseous decomposition products of the ammonium sulphate are copiously evolved. (B) Alunite, muscovite, orthoclase, and leucite are treated as in (A) to produce a potash and nitrogenous fertiliser. —J. H. J.

Fertilisers; Manufacture of — J. R. Robinson, Stockton-on-Tees. Eng. Pat. 116,758. (Appl. Nos. 8858, June 20, and 18,802, Dec. 18, 1917.)

A MIXTURE of cellulosic material, e.g., peat, peat moss, rape meal, castor meal, seed husks or refuse, sweepings from maltings, residue from beet sugar refineries, and the like, and soil, or soil-like material, e.g., decayed vegetable matter, cesspool sludge, road sweepings, destructor residues, and the like in a finely divided condition, either alone or together with phosphatic material such as steamed bone flour, basic slag, ground copralites or other mineral phosphates, and/or potassium sulphate, potassium chloride, kainite, flue-dust, etc., is treated with a lime compound, e.g., quicklime, limestone, dolomite, etc. Common salt, especially when kainite is not used, and magnesium sulphate may also be added. When the chemical action has ceased, yeast, mixed to a thin paste with water, is added and thoroughly incorporated with the mass and the whole allowed to remain at a suitable temperature to permit the yeast to multiply and act on the cellulosic matter, etc., converting it into plant-food. —L. A. C.

Ammonium sulphate; Process of preventing agglomeration and hardening of — during storage. F. Dahl, Hamborn. Ger. Pat. 305,715, Nov. 25, 1915.

A SALT of potassium or sodium, such as the sulphate or chloride, is added to ammonium sulphate soon after its manufacture, if desired in the proportion required by plant life. The preparation remains permanently dry, and may be stored in paper bags. —C. A. M.

XVII.—SUGARS ; STARCHES ; GUMS.

Seliwanoff reaction [for detection of ketoses or sucrose]; A modification of the —. F. Weehuizen. Rec. trav. chim. Pays-Bas, 1918, 37, 302—303.

For the detection of a ketose or sucrose in a mixture of sugars, the mixture is added to a saturated solution of hydrogen chloride in alcohol containing a little resorcinol. A cherry-red coloration appears in the cold in three minutes if a ketose is present. The acid solution must be saturated with respect to the acid and free from water. For the detection of sucrose in milk, 10 c.c. of the milk is shaken with 30 c.c. of absolute alcohol, filtered, and 10 c.c. of the filtrate evaporated to a syrup, cooled, treated with 3—4 c.c. of the alcoholic acid solution and 50 mgrms. of resorcinol, and the mixture triturated. A red colour is developed in three minutes if the milk contains 0.5% of sucrose. —W. G.

PATENT.

Honey; Preparation of artificial — containing iron. W. Schmitz, Berlin, and E. Jansen, Berlin-Wilmersdorf. Ger. Pat. 303,754, Mar. 28, 1915.

THE hydroxide or other suitable compound of iron is added to sugar during inversion whereby salts of iron are produced with the acid used for inversion and saccharates of iron with the sugar.

—H. J. H.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Influence which the plant function of — exercises on the yield of alcohol: new interpretation of fermenting power. L. Lindet. Comptes rend., 1918, 166, 910—913.

THE author considers that fermenting power must be considered as a function of the plant power, as measured by the amount of sugar consumed by unit quantity of yeast for its plant life, and the zymase power, as measured by the sugar consumed by unit quantity of yeast in accomplishing its zymatic function. The experimental results show that the less yeast there is and the more the fermentation is prolonged, the greater is the proportion of sugar consumed by the plant function and the lower is the yield of alcohol. Lowering of the temperature has a greater effect on the duration of the fermentation than on the weight of yeast produced. —W. G.

Yeast foods; Carbohydrates other than sugar [e.g., waste liquors from cellulose manufacture] which are suitable as —. T. Bokorny. Chem.-Zeit., 1918, 42, 260.

THE waste liquors from cellulose manufacture may be used for growing yeast; these liquors contain mannose, levulose, galactose, and xylose. Pentoses and dextrins may also be used for the purpose, but arabinose, rhamnose, and methylpentoses are of little value. —W. P. S.

Lactic acid formation; Influence of lactic acid on —. W. van Dam. Biochem. Zeits., 1918, 87, 107—122.

INVESTIGATIONS were made to ascertain whether the stoppage of fermentation by the coccal form of bacteria is due to the action of the hydriion of the lactic acid produced or to the undissociated molecule. The conclusion is drawn that the stoppage is due to both. If sodium lactate is added to the whey, further acid formation ceases when the concentration of the undissociated molecule reaches 0.02N. In such cases, the final hydriion concentration fails to reach the toxic amount of about 10×10^{-5} . If hydrochloric acid is added to the whey before inoculation, so much lactic acid is produced as to bring the final hydriion concentration to 10×10^{-5} — 20×10^{-5} . In this case the amount of undissociated lactate remains below the toxic amount. Attention is called to the fact that certain conclusions of other authors as to the value of nitrogenous nutrients is vitiated by their failing to take into account their buffer action. (See also J. Chem. Soc., Aug., 1918.) —S. B. S.

Potassium requirements of bacteria. G. P. Koch. Soil Sci., 1918, 5, 219—224.

WORKING with cultures of *B. subtilis* it was found that potassium is essential to the development and activities of the organisms. In its absence, magnesium sulphate and calcium phosphate cannot be utilised by the organism. Measuring the activity of the *B. subtilis* from the amount of ammonia formed by it from dialysed peptone, the maximum activity and development was obtained by supplying 0.24 mgrm. K₂O in addition to the 0.1 mgrm. present in the peptone, in 100 c.c. of solution. Any amount above this did not further increase the activity of the bacteria. —W. G.

Enzymes and bacteria; Action of cyanhydrins on —. M. Jacoby. Biochem. Zeits., 1918, 87, 129—134.

THE action of the urease of soya bean is strengthened by the presence of the cyanhydrin of

acetaldehyde, but inhibited by the corresponding propaldehyde derivative. Both compounds inhibit strongly the formation of enzymes by bacteria, whilst they exert a very moderate deleterious action on the bacteria themselves. (See also J. Chem. Soc., Sept., 1918.)—S. B. S.

Concentration of sulphite waste liquors. Oman. See V.

Nucleic acid and its analytical examination. Chapman. See XX.

Proteolytic enzymes: Process for producing an extract of —. Kancagafuchi Boseki Kabushiki Kwaiisha, Tokyo-Fu, Japan. Eng. Pat. 106,504, May 16, 1917. (Appl. No. 7051 of 1917.) Under Int. Conv., May 16, 1916.

PROTEOLYTIC enzymes capable of dissolving sericin and therefore of value in the manufacture of silk, as well as for medicinal purposes, are extracted from cocooning insects of the family *Bombycidae*, or their discharges or secretions (cast-off skins, etc.), obtained as waste products in sericulture and filature), by digesting with water, e.g., for 6–48 hours at 5°–10° C., or for 5–15 mins. at 40° C., separating the extract by pressure and concentrating at a low temperature, e.g., in *vacuo* at 45° C. The products thus obtained may be used, or if necessary the enzymes may be precipitated therefrom by known means.—J. H. L.

Wine; Non-alcoholic — and process of making same. J. Russell, New York. U.S. Pat. 1,264,564, Apr. 30, 1918. Date of appl., July 5, 1917.

WINE is heated and the alcoholic and other vapours are condensed, and the condensed liquid is intimately mixed with melted vaseline in order to absorb the ethereal components and separate them from the alcohol. The unabsorbed liquid is removed and the other components are recovered from the vaseline by distillation and returned to the wine.

—J. F. B.

Process of treating the residual liquor obtained in the hydrolysis of cellulosic materials. U.S. Pat. 1,261,328. See V.

Densimetric methods and appliances. Eng. Pat. 115,662. See XXIII.

XIXA.—FOODS.

Food substitutes; Directions for the examination and licensing of —. German Food Substitutes Commission. Z. anal. Chem., 1918, 57, 170–176.

GENERAL directions are given for deciding as to the use of various food substitutes, the points considered being the nature of the substance, its keeping qualities, cost, raw materials required for its preparation, etc. Baking powders must yield 235 to 285 grms. of carbon dioxide from the amount of the powder used per 0.5 kilo. of flour; the excess of sodium bicarbonate present must not exceed 0.8 gm.; the use of bisulphates, bisulphites, alum, etc., is not permitted, but the powder may contain 20% of calcium carbonate. All powders having the general composition of baking powder must be sold as such and not as egg-powder, etc. Egg powders must have a food value equal to that of eggs, otherwise the word "egg" cannot be used in their description; they must not contain glue or gelatin. Vanillin powder must contain at least 1%, and vanillin salt at least 2% of vanillin, and the latter

may not be substituted by piperonal or coumarin. Spice substitutes must have a strength equal to that of the spices they replace; the sand content must not exceed 2.5%. Tea substitutes containing a large proportion of valueless vegetable substance are not permitted; the description of tea substitutes must not be such as would indicate that they consist of real tea. Other substitutes mentioned are those for pudding powder, jellies, seasonings, honey, etc.

—W. P. S.

Fat in milk; Additive factors for the calculation of — from the specific gravity and total solids. L. J. Harris. Analyst, 1918, 43, 263–267.

The percentage of fat in milk may be rapidly calculated by adding together two factors respectively corresponding with the sp. gr. and total solids. The factors are obtained as follows:—

$$t = \frac{T}{1.2} - 8; s = 8 - \left(\frac{G}{4.8} + 0.116 \right),$$

where t represents the factor for total solids, s that for the sp. gr., and T and G have the same meaning as in Richmond's formula. Determination of the total solids by direct evaporation of 5 grms. of milk in a porcelain dish gives concordant results. The two sets of factors for sp. gr. from 1.0220 to 1.0370, and for total solids 10.00 to 13.99% have been embodied in tables, and the percentage of fat calculated by means of them almost invariably agrees within 0.1% with that determined by the Werner-Schmidt method, and frequently the agreement is as close as 0.01%.—C. A. M.

Gerber test [for milk]; Conditions affecting accuracy in the —. F. E. Day and M. Grimes. Analyst, 1918, 43, 215.

THE most concordant results are obtained when the centrifuging is maintained for three mins. at 1000 revs. per min. In the case of skimmed milks, re-heating followed by a second centrifuging is necessary, but with new milks this procedure is liable to give irregular results. It is important to pay attention to the temperature of the fat at the moment of reading its volume, and it is recommended that the tube be calibrated with an oil which is liquid at the ordinary temperature. (See also this J., 1918, 278A.)—W. P. S.

"Cocoa Ivas"; Analysis of —. J. L. Baker and H. F. E. Hulton. Analyst, 1918, 43, 189–197.

"Cocoa teas" consist of cacao shell or of cacao shell mixed with full-fatted cacao nib. Results of analyses of four samples of the product are given in the following table:—

	A.	B.	C.	D.
	%	%	%	%
Moisture	11.0	10.8	8.76	10.44
Fat	3.0	20.05	12.65	4.7
Total ash	15.0	8.0	7.48	10.04
Ash soluble in water	2.2	5.78	5.14	6.68
Ash insoluble in hydrochloric acid	5.14	0.36	0.34	0.5
Alkalinity of soluble ash, as K ₂ O	0.33	3.85	3.08	4.28
Nitrogen	2.03	2.38	2.38	2.66
Crude fibre	12.8	14.87	14.87	16.62
Substances soluble in cold water	21.7	17.5	20.2	22.0

Sample A evidently consists of shell without any admixture of nib; the high ash is due to the shell having been obtained from beans which had been "clayed" or "earthed." B consists of a mixture of shell, 61%, and nib, 36%, which has been alkalisied. Sample C has also been alkalisied and contains shell, 86%, and nib, 14%. The sample D consists wholly of shell.—W. P. S.

Cocoa and cacao products; Estimation of shell in —. J. L. Baker and H. F. E. Hulton. Analyst, 1918, 43, 197—201.

THE quantity of shell in cocoa is usually estimated from the levigation residue, the nitrogen content, or the crude fibre content. The authors have investigated the accuracy of these methods, mainly with the purpose of ascertaining the possibility of distinguishing between Grade A and Grade B cocoas mentioned in the Cocoa Powder Order, 1918; this Order provides that Grade A cocoa shall not contain more than 2% of shell, whilst Grade B cocoa shall not contain more than 5% of shell and not less than 22.5% or more than 30% of cacao butter. In the levigation process 10 grms. of the powder is extracted for 24 hrs. with ether in a Soxhlet apparatus, then dried, mixed into a paste with water, transferred to a 500 c.c. cylinder, and diluted to 400 c.c.; after mixing and settling for 15 mins., the supernatant liquid is drawn off, the sediment diluted to 400 c.c., the liquid drawn off after 10 mins., and this operation twice repeated with 5 mins.' settling. The sediment is then rinsed into a platinum basin, evaporated, dried, and weighed, an allowance being made for the ash present. The figures adopted for sediment are 3% for dry, fat-free nib and 30% for dry, fat-free shell. The percentage of shell in the original sample is calculated from the formula:

$$S\% = \left(\frac{100M}{100 - (F+W)} \right) - 3 \left(\frac{100 - (F+W)}{27} \right), \text{ where } M = \text{percentage of levigation sediment, } F = \text{percentage of fat, and } W = \text{percentage of water in the sample.}$$

If the percentage of shell is calculated from the crude fibre content the formula used is:

$$S\% = \left(\frac{K \times 100}{100 - (F+W)} - 5.7 \right) \times \frac{100 - (F+W)}{11.1}, \text{ where } K = \text{percentage of crude fibre. The fibre contents of dry, fat-free nib and shell are 5.7 and 16.8\%, respectively. The percentage of shell is calculated from the nitrogen content by the formula:}$$

$$S\% = 2.17(100 - F - W) - \frac{100N}{2.26}, \text{ where } N = \text{percentage of nitrogen; the nitrogen contents of dry, fat-free nib and shell are 4.9 and 2.64\%, respectively. The results of analyses of various samples by the three methods were as under:—}$$

	Moisture.	Fat.	Levigation residue	Nitrogen.	Crude fibre.	Percentage of shell calculated from		
	%	%	%	%	%	Levigation.	Nitrogen.	Crude fibre.
A	9.3	12.0	17.37	2.66	9.65	55.7	53.0	46.8
B	2.0	28.0	2.57	3.57	4.04	1.7	0.0	7.6
C	1.7	28.6	4.23	3.29	—	7.9	6.3	—
D	4.2	32.6	3.70	3.22	—	6.6	0.0	—
E	2.0	25.5	0.75	3.29	—	0.0	11.7	—
F	4.7	21.9	3.06	3.50	—	3.2	4.3	—

The methods are suitable for the estimation of considerable proportions of shell but appear to be inadequate for distinguishing between cocoas of Grades A and B where the difference in shell content is small. In the case of cocoa powder, the fat content cannot be used as a basis in calculating the percentage of shell since the cocoa has been partially de-fatted.—W. P. S.

Cacao "germ." P. A. E. Richards. Analyst, 1918, 43, 214.

A SPECIMEN of cacao "germ" obtained from roasted cacao bean, and free from nib and shell, contained fat, 3.58, and moisture, 7.2%. The fat-free, dry

material contained: nitrogen, 5.5; crude fibre, 3.65; total ash, 7.3; soluble ash, 4.0; cold-water extractives, 28.7%. The alkalinity of the soluble ash was 1.69% (as K_2O) and the butyro-refractometer value of the fat was 66 at 35° C. The levigation method yielded a residue of 38.3%.—W. P. S.

PATENTS.

Bread and ingredients therefor; Manufacture of —. J. Chandler, London. Eng. Pat. 115,556, Aug. 16, 1917. (Appl. No. 11,788 of 1917.)

LINSEED is heated with water in such proportion that the filtered extract sets to a thin jelly on cooling; for convenience in handling and weighing it may be stiffened by addition of a small quantity of gelatin. The product is used in bread-making, e.g., 1—4 lb. to 280 lb. of flour, to improve the edible and keeping qualities of the bread, especially when a large proportion of flour other than wheat flour is used.—J. H. L.

Bran; Treatment of — for incorporation in bread. H. Feddersen, Berlin. Ger. Pat. 303,577, July 18, 1911.

THE bran is made into a dough, left for a time under conditions suitable for enzyme action, and then, while warm, subjected to wet grinding prior to incorporation with dough for bread. Palatability and availability of cell contents are increased by the treatment, which also shortens the time necessary for reducing the bran to the required degree of fineness, and therefore reduces the risk of infection with harmful ferments.—H. J. H.

Butter-fat; Sterile — and method of producing the same. C. E. Rogers, Detroit, Mich. U.S. Pat. 1,264,336, Apr. 30, 1918. Date of appl., Jan. 17, 1912.

BUTTER is melted at a temperature not exceeding 180° F. (82° C.), and the fat is separated from the casein, etc., freed from moisture at about 212° F. (100° C.), and sterilised, under exclusion of air, at about 240° F. (115.5° C.).—C. A. M.

Margarine; Apparatus for the manufacture of —. C. J. A. Rydberg, Copenhagen. Eng. Pat. 116,603, Aug. 8, 1917. (Appl. No. 11,397 of 1917.)

THE constituents of the margarine are emulsified in a rotating container, and the emulsion crystallised on hollow rollers arranged in pairs within the container, and provided with means for interior cooling. The emulsion may also be kneaded by the cooling rollers arranged eccentrically within the container.—C. A. M.

Fruits, vegetables, and similar articles; Method of and apparatus for dehydrating —. G. H. Benjamin, New York. U.S. Pat. 1,264,600, Apr. 30, 1918. Date of appl., July 10, 1917.

A CURRENT of air at definite temperature and humidity is passed over a portion of the material to be dried, then heated to its original temperature, mixed with a fresh quantity of air proportional to

the increased humidity, and passed over a second portion of the material, this process being repeated over successive portions until the whole of the material has been subjected to air currents. Apparatus for this process comprises a pump, an inlet and outlet for the air, with a series of cells between the inlet and outlet, in which removable trays are arranged in superposed zig-zag order, means for heating the air between each series of trays, and for regulating the volume and temperature of the air during its passage through the cells.—C. A. M.

Food product and process of producing same.

R. Graham, Cupar, Scotland. U.S. Pat. 1,264,876, Apr. 30, 1918. Date of appl., May 28, 1917.

WHOLE wheat bread is prepared by treating wheat bran and middlings or other bran-containing material with a diastatic and peptic agent, such as malted wheat flour, keeping the mixture warm for about 12 to 36 hours, adding white flour to the product, making it into dough, and baking for at least 3½ hours at a relatively low oven temperature. The wheat malted for this purpose is dried and kept for about 3 months at temperatures gradually falling from about 200° F. to 100° F. (93° to 38° C.).

—C. A. M.

XIXB.—WATER PURIFICATION; SANITATION.

Drinking water; Purification of —. C. Kippenberger. Ber. deuts. Pharm. Ges., 1918, 28, 230—240.

A SHORT general account of processes of purification and sterilisation of drinking water used in Germany, covering the application of bleaching powder, chlorine gas, permanganate, vegetable and animal charcoal, ultra-violet light, and ozone.—J. H. J.

Drinking water; Removal of iron from —. O. Beck. Z. angew. Chem., 1918, 31, 112, 115—116.

THE water in the district of Antwerp, in so far as it is not derived from deep wells, has to a large extent the character of moorland water, and, owing to the deposits of iron pyrites in the soil, contains a high proportion of iron as bicarbonate and as ferrous sulphate. Treatment of the water with a mixture of bleaching powder and sodium chloride, and then with Schäffer's aluminium sulphate-charcoal (blood charcoal containing 16.6% of aluminium sulphate), and filtration through a Dunbar filter, removed the iron and gave a sterile water; but it was found that after standing, the water gave a deposit of calcium sulphate, and acquired a bitter taste due to aluminium compounds, whilst the filter rapidly became choked by the sediment. These drawbacks were obviated by a method in which 250 c.c. of the water is agitated with 400 c.c. of 3% hydrogen peroxide solution, which is added in successive small quantities, this being followed by 100 grms. of finely powdered anhydrous sodium carbonate. The precipitate subsides within 30 mins., and the water can be readily filtered, yielding a filtrate free from iron and practically sterile. The method is suitable for the removal of not too excessive quantities of iron from water, but frequent renewal and disinfection of the filter is advisable.

—C. A. M.

Sewage disposal; The Miles acid process for —. Met. and Chem. Eng., 1918, 13, 591—594.

A SMALL portion of the sewage to be treated is pumped through an absorption tower, where it

meets a counter current of sulphur dioxide. After saturation, the sewage is returned to the main sewer to be mixed with the bulk of the sewage. The whole then flows through two settling tanks in series, where four hours' sedimentation is allowed. According to R. S. Weston, about a ton of sulphur dioxide per million gallons of sewage is used, or 382 tons of nitre cake with 200 lb. of sulphur dioxide may be used instead. The sludge collects at the bottom of the tanks, and when pumped out contains 80—92% of water. The drying of the sludge is difficult owing to the large amount of crude fibre (up to 40%), but this may be screened out, pressed down to 50% of water, and extracted separately. The dried sludge is extracted, and the grease obtained consists of glycerides and fatty acids in about equal proportions, and may amount to 430 lb. from a million gallons of sewage. The residue left contains 45% NH₄ and 1—2% P₂O₅. The effluent from the settling tanks contains 800—1200 lb. K₂O and 50 lb. P₂O₅ per million gallons, and has an acidity of 0.066—0.01% as SO₂. It is nearly sterile, and is without odour. The process is in operation in a 10,000-gallon test plant at New Haven, Connecticut.—J. H. J.

Albuminoid ammonia; Determination of — in liquids containing gas liquor. H. F. Stephenson. Analyst, 1918, 43, 215—216.

THIOCYANATES must be removed before albuminoid ammonia can be determined in liquids containing gas liquor, since thiocyanate yields ammonia when boiled with alkaline permanganate solution. A definite volume of the sample (which should be alkaline) is treated with a quantity of aluminium sulphate sufficient to give a decided precipitate, filtered through an asbestos filter, the filtrate acidified with nitric acid, the thiocyanate precipitated by the addition of silver nitrate, and the mixture again filtered. The filtrate is then distilled in the usual way for the determination of the albuminoid ammonia. Owing to the slight solubility of silver thiocyanate, a control determination should be made on distilled water to which a small quantity of thiocyanate has been added and a corresponding correction applied to the results obtained; this correction is practically a constant.—W. P. S.

Disinfection; Application of the mass law to the process of —. R. E. Lee and C. A. Gilbert. J. Phys. Chem., 1918, 22, 348—372.

FROM a study of the velocity of disinfection in the cases of *B. typhosus* with 0.2% phenol at 37.5°, anthrax spores with mercuric chloride at 20°, and *Staphylococcus pyogenes aureus* with 0.2% phenol at 20° C., it is shown that disinfection is an orderly time process closely analogous to a chemical reaction. A definite logarithmic relationship between velocity and concentration has been established in all cases examined. (See also J. Chem. Soc., Aug., 1918.)—J. F. S.

Arsenates; Calcium — [as insecticides]. R. H. Robinson. J. Agric. Res., 1918, 13, 281—294.

WHEN commercial calcium arsenates have been used in orchards as a spray for fruit trees, it has led to burning of the foliage owing to their solubility in water, and experiments were made to determine whether an improved product could be produced. Pure calcium arsenate and calcium hydrogen arsenate were prepared. When tested for solubility by shaking with water at 25° C., calcium hydrogen arsenate yielded a solution containing 0.37 grm. per 100 grms. of water, which would be sufficient to render it unsuitable as a spray. Calcium arsenate, however, was so sparingly soluble (0.013 grm. at 25° C.) as to render it safe for use, and it was also

sufficiently stable in presence of acid and alkali. The addition of 1 part of lime to every 2 parts of either arsenate renders it more nearly insoluble, and would make the calcium hydrogen arsenate available for spraying. It was found that either arsenate could be mixed with wet and dry lime-sulphur without the ingredients losing their stability. (See also J. Chem. Soc., 1918, ii., 222.)—J. H. J.

Recovery of grease from waste materials by the solvent extraction process. Garner and Carmichael. See XII.

PATENTS.

Water softener; Process for producing a —. G. H. Widner. Eng. Pat. 107,197, May 17, 1917. (Appl. No. 7070 of 1917.) Under Int. Conv., May 20, 1916.

SEE U.S. Pat. 1,207,826 of 1916; this J., 1917, 161. Instead of heating the aluminum silicate mineral with salt, it may be heated alone and then steeped in salt water.

Water-softening material; Process for producing a —. G. H. Widner, Des Moines, Iowa. Eng. Pat. 116,023, May 17, 1917. (Appl. No. 15,744 of 1917.)

THE source of the material is natural clay containing preferably 20% of alumina and 53% of silica. It is reduced to a fine mud in presence of sodium chloride, then concentrated and forced under pressure through a screen which delivers the material in fine strings; these are cut off in suitable lengths, dried, and baked at 600° C. until hard enough to resist the powdering action of water. (See also U.S. Pat. 1,207,826; this J., 1917, 161.)—J. H. J.

Sterilising water by means of ozone; Apparatus for —. L. H. E. Bégot, Paris, Assignor to Steynis Ozone Co. U.S. Pat. 1,264,360, Apr. 30, 1918. Date of appl., Aug. 3, 1916.

THE water to be sterilised operates an injector which draws air through an ozone generator. An electric circuit supplies current to the generator. In the circuit is a rotating contact arranged to be driven by a motor operated by the water to be sterilised.—J. H. J.

Water; Sterilisation of — and removal of iron and manganese therefrom by electrolytic means. F. Tiemann, Berlin. Ger. Pat. 301,585, Apr. 23, 1916.

THE water is caused to flow through the anode compartment of a diaphragm electrolytic cell, and a conductor of the first order, indifferent to oxygen, e.g., carbon or pyrolusite, is added to it continuously, in the form of fine powder or granules, which will remain in suspension in the flowing water. The ionised oxygen produced oxidises and precipitates iron and manganese and destroys bacteria. After settling, the sludge is used again, and the water is filtered through sand.

Water; Sterilisation of — and removal of iron and manganese therefrom by electrolytic means. F. Tiemann, Berlin. Ger. Pat. 302,225, Sept. 30, 1916. Addition to Ger. Pat. 301,585 (see preceding abstract).

Economy of apparatus and current are effected by subjecting only a small portion of the water to

electrolysis with the addition of conducting material—preferably carbon grains—in suspension. The ionised oxygen is adsorbed or absorbed by the carbon grains and exerts its purifying action when the treated water is mixed with the main bulk of untreated water.—H. J. H.

Water; Sterilisation of — and removal of iron and manganese therefrom by electrolytic means. F. Tiemann, Berlin. Ger. Pat. 302,227, Oct. 11, 1916. Addition to Ger. Pat. 301,585 (see preceding abstracts).

INSTEAD of suspending the conducting material in the water, it is used as a filling material, in the form of hollow balls or the like, in the anode chamber, being retained in place by screens. The water flows over and through the material (e.g. carbon, platinum, pyrolusite).—B. V. S.

Boiler-feed water; Process for removing gases from, softening, and preheating —. I. P. Winer, Warsaw. Ger. Pat. 302,643, Oct. 8, 1913.

IN the upper part of the boiler is a receptacle having an elongated tubular portion, similar to a smoker's pipe; the tube passes through the wall of the boiler, extends downwards, and then re-enters the boiler near the bottom. The feed water is forced through a set of nozzles arranged within the bowl of the receptacle, and is sprayed against the wall of the boiler, whence it is deflected by means of guide-plates into the receptacle, and thence into the boiler. The tubular extension of the receptacle, outside the boiler, is connected to a gauge-glass.

Separation and settlement of solids and semi-solids from sewage liquids and analogous liquids. W. Clifford, Wolverhampton, and Jones & Attwood, Ltd., Ambleside, Staffs. Eng. Pat. 115,872, May 17, 1917. (Appl. No. 7064 of 1917.)

A TANK in the form of an inverted cone is used, into which the sewage is brought by a horizontal pipe, the mouth of which directs the current into a much wider bucket suspended in the upper part of the tank. This has the effect of breaking up the current and causing eddies which pass upwards out of the bucket. These eddies are prevented from spreading by a guard wall of much wider diameter surrounding the bucket and carried upwards above the level of the liquid in the tank. The guard wall is open at the bottom, and the liquid passes from it with a low velocity and without any disturbing effect upon the deposited sludge in the bottom of the tank. The liquid finally passes out of the tank over a weir at the circumference. The sludge is withdrawn through a pipe in the apex of the cone.

—J. H. J.

Sewage and other foul liquids; Apparatus for aerating —. R. Ames, Brighton. Eng. Pat. 115,933, June 19, 1917. (Appl. No. 8785 of 1917.)

THE sewage enters a channel situated alongside a treatment tank, from which it is siphoned into a trough which travels over the tank. The sewage flows into the tank through vertical pipes with bell-mouths, which depend from the trough to the bottom of the tank. Hollow pipes pass down the centres of the vertical pipes and carry horizontal fans at their lower ends, revolving inside the bell-mouths, whereby vortices are created and air is drawn down the pipes. The propellers of the fans are hinged in order to permit of the fans being drawn up the pipes when they require to be cleaned. A further supply of air is obtained through a pair of tubes from the surface to the inside of each bell-mouth.—J. H. J.

Sewage sludge; Process for removing fat from —. C. Stiepel, Berlin-Steglitz. Ger. Pat. 305,768, Aug. 6, 1915.

THE fat is converted into calcium soap which is then extracted with a halogen compound of a hydrocarbon, such as carbon tetrachloride, trichloroethylene, etc. The difficulty of using an acid process in presence of much calcium carbonate is thus obviated.—C. A. M.

Process of making exchange silicates. Process of making exchange bodies. U.S. Pats. 1,263,706 and 1,263,707. See VII.

Utilisation of nitre-cake [for preparation of an insecticide]. Eng. Pat. 116,181. See X.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine in opium; Determining —. C. A. Hill. Analyst, 1918, 43, 214.

THE use of a Gooch crucible furnished with a filter paper is recommended for collecting the precipitated morphine obtained in the B.P. method for the determination of this alkaloid; the precipitate is washed with morphinated water in the usual way.—W. P. S.

Morphine; Effect of codeine in hindering the precipitation of — by ammonia from a solution of its lime compound. H. E. Annett and H. Singh. Analyst, 1918, 43, 205–215.

THE presence of codeine decreases the amount of morphine precipitated from its calcium hydroxide solution by ammonia in the presence of alcohol and ether (B.P. method), the effect increasing as the ratio of codeine to morphine increases. Considerably higher results for morphine in opium are obtained if the codeine is removed by extracting the solution with toluene previous to the precipitation with ammonia. This applies particularly to Indian opiums with a high codeine content. (See also J. Chem. Soc., Aug., 1918.)—W. P. S.

Brucine; Colorimetric determination of — in presence of strychnine. A. Wöber. Z. angew. Chem., 1918, 31, 121.

DOWZAN's method of determining brucine by means of the colour reaction with nitric and sulphuric acids (this J., 1902, 1560) has the drawback that the original red coloration decreases with varying velocity according to the concentration of the alkaloidal solution, whilst strong nitric acid gives a yellow coloration with strychnine, and the brucine reaction is not sensitive with dilute nitric acid. Trustworthy results may be obtained by using as the reagent a mixture of equal vols. of strong nitric acid (sp. gr. 1.4) and 20% sulphuric acid, and adding immediately after the reaction, 2 c.c. of a saturated aqueous solution of potassium chlorate. The reaction is capable of detecting 0.1 mgrm. of brucine in 50 c.c. of a solution containing 0.1 gm. of strychnine. The standard solution of brucine used for the colorimetric comparison should also contain 0.1 gm. of strychnine, the effect of this alkaloid on the reaction being largely independent of the concentration. (See also J. Chem. Soc., Aug., 1918.)

—C. A. M.

Ricinine. B. Böttcher. Ber., 1918, 51, 673–687.

CASORON seed contains about 0.15% of the alkaloid, ricinine, which is the methyl ester of ricininic acid. This and its degradation products show the reactions of pyridine-carboxylic and glyoxalim-carboxylic (e.g. histidine) acids. Combining these facts with what was previously known about ricinine, the following formula is proposed:—

(See further J. Chem. Soc., 1918, 1, 301.)

—J. C. W.

Choline; Microchemical tests for —. N. Schoorl. Pharm. Weekblad, 1918, 55, 363–369.

AN aid to the identification of choline is furnished by the formation of double salts by its hydrochloride with the chlorides of platinum and of gold, and with mercuric and bismuth iodides. The microchemical characteristics of these salts and of the picrate and picrolonate are described.—A. J. W.

Nucleic acid and its analytical examination. A. C. Chapman. Analyst, 1918, 43, 259–263.

NUCLEIC acid derived from yeast, frequently described as "plant-nucleic acid," is a white friable substance with the composition

THE commercial product should be white or nearly so, and should dissolve in an aqueous solution of sodium acetate, or in dilute solutions of ammonia or of sodium or potassium hydroxides, to form bright and nearly colourless solutions. The acid should be precipitated as a white curd-like substance from an aqueous solution of the sodium salt, and the precipitate should dissolve on further addition of a large excess of hydrochloric acid. Sodium nucleate gives a bulky greenish-blue precipitate with a solution of copper acetate acidified with acetic acid; a white flocculent precipitate, becoming granular, with calcium chloride in presence of a few drops of acetic acid; and a white gelatinous precipitate with silver nitrate. In the biuret test for proteins it should give, at most, only a slight indication of purple. Inorganic phosphate is detected by adding to a solution of the acid in considerable excess of ammonium or sodium acetate a few drops of acetic acid and a little uranium acetate. In the absence of inorganic phosphate the flocculent precipitate should dissolve completely on boiling. Nitrogen may be determined by Kjeldahl's method, and phosphorus by fusing the sample with six times its weight of sodium carbonate containing 10% of potassium nitrate, and determining the phosphoric acid by the molybdate or magnesia methods. Commercial nucleic acid of good quality should contain not much less than 15% of nitrogen (theory 16.1%) and 9% of organic phosphorus calculated on the moisture-free substance (theory 9.5%). If the ratio of organic phosphorus to nitrogen (1:1.7) is approximately correct, the presence of material quantities of the products of hydrolysis is excluded. Nucleic acid may be identified by the identification of guanine and adenine in the products of hydrolysis. For this purpose 10 grms. of the acid is heated in a boiling water-bath for 2 hours with 40 c.c. of 10% sulphuric acid in a small flask fitted with an air condenser. Strong ammonia is then added until present in an excess of about 2%, and the precipitated guanine is filtered off, washed with 1% ammonia solution, dissolved in the smallest possible amount of dilute sulphuric acid, and the base reprecipitated by means of ammonia, and converted into its hydrochloride.

which may be identified by well-known tests. The ammoniacal filtrate is acidified with sulphuric acid, and the adenine precipitated as a cuprous compound by means of 10% copper sulphate solution. The adenine copper compound is suspended in water, decomposed with hydrogen sulphide, the filtrate evaporated to dryness, the residue dissolved in dilute sulphuric acid, and the adenine sulphate allowed to crystallise, and identification tests applied. (See also J. Chem. Soc., Aug., 1918.)—C. A. M.

Acetylsalicylic esters. A. Astruc. J. Pharm. Chim., 1918, 17, 386—388.

In the analysis of methyl and ethyl acetylsalicylates, determinations should be made of the ester content by saponification. In addition to giving correct saponification values, the substances should have a neutral reaction, since mixtures of 92.78% of acetylsalicylic acid and 7.22% of methyl alcohol, or 86.53% of acetylsalicylic acid and 13.47% of ethyl alcohol, have the same saponification values as pure methyl and ethyl acetylsalicylates, respectively.—W. P. S.

Chloroform; Preparation of — from ethyl alcohol. K. Ukita. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 219—226.

PURE chloroform can be obtained in good yield from alcohol by Besson's process; the cost is considerably less than when acetone and bleaching powder are used as raw materials, especially under present conditions, and the method affords a useful means of utilising waste chlorine in bleaching powder and electrolytic alkali works. Chlorine is passed into alcohol until the density of the liquid reaches 35° B. (sp. gr. 1.32), or until two layers which are formed at first become united. A mixture of bleaching powder, milk of lime, and water (500 grms., 100 grms., and 2 litres respectively per 100 grms. of alcohol) is then added, and the chloroform is recovered by distillation. Yield, 95—98 grms. per 100 grms. of alcohol.

Urotropine and formaldehyde; Behaviour of — in the organism. E. Salkowski. Biochem. Zeits., 1918, 87, 143—162.

THE most satisfactory test for detecting formaldehyde in the presence of urotropine is that of Jorissen as modified by Vanino (use of phloroglucinol and sodium hydroxide). Solutions of urotropine cannot be kept for any length of time without decomposition except in the presence of small amounts of sodium carbonate (0.1—1%). (See also J. Chem. Soc., Sept., 1918.)—S. B. S.

Organic halogen compounds; Catalytic reduction of —. K. W. Rosenmund and F. Zetzsche. Ber., 1918, 51, 578—585.

THE removal of halogen atoms from organic compounds by the action of hydrogen in the presence of a catalyst has recently been developed into methods for estimating halogens (see Kelber, this J., 1917, 568). The authors give an account, with examples, of their experience with palladinised barium sulphate and colloidal palladium as catalysts.

—J. C. W.

Aldehydes; New method for the preparation of —. K. W. Rosenmund. Ber., 1918, 51, 585—594.

ONE of the best methods for the preparation of aldehydes yet discovered consists in the hydrogenation of the acid chlorides in boiling xylene or cumene with palladinised barium sulphate (5% of metal) or nickel as the catalyst. Examples are given, including the preparation of *p*-methylcarbonatobenzaldehyde, $\text{CH}_3\text{O-CO-O-C}_6\text{H}_4\text{-CHO}$, m.pt. 18.5° C., in 95% yield. (See further J. Chem. Soc., 1918, i., 300.)—J. C. W.

Aldehydes; New method for the preparation of —. II. Synthesis of gallaldehyde. K. W. Rosenmund and F. Zetzsche. Ber., 1918, 51, 594—602.

THE carbomethoxy- and acetyl-derivatives of gallic acid are converted into the acid chlorides, these are reduced to the aldehydes by the new method (see preceding abstract), and then hydrolysed to gallaldehyde. This dissolves freely in water and alkalis, and is even more acidic than acetic acid. (See further J. Chem. Soc., 1918, i., 300.)—J. C. W.

Mustard oil; Iodine value of —. E. G. Raynes. Analyst, 1918, 43, 216—217.

THE iodine values of various mustard oils were found to be as follows: Expressed mustard oil, 119.6 to 121.0; extracted black mustard oil, 114.4; extracted white mustard oil, 104.7 to 108.6. The values recorded previously by certain authors appear to be too low.—W. P. S.

Volumetric determination of chlorine, bromine, cyanogen, and mercuric ions. Votocek. See XXIII.

PATENTS.

Aluminium; Preparing water-soluble compounds of — with organic acids. H. Sefton-Jones, London. From J. A. von Wülling, Berlin. Eng. Pat. 115,463, May 4, 1917. (Appl. No. 6379 of 1917.)

PREPARATIONS of aluminium acetate or formate, directly soluble in water, for pharmaceutical and technical use, are produced by evaporating to dryness solutions containing the salts named together with alkali or alkaline-earth salts of the same acids; e.g., a mixture of 224 parts of aluminium formate solution of 23° B. (sp. gr. 1.19) with a solution of 40 parts of magnesium formate, or 34 parts of sodium acetate, yields readily soluble products when evaporated to dryness *in vacuo*.
—J. H. L.

Metal albumin combinations; Manufacture of —. O. Imray, London. From Soc. of Chemical Industry in Basle, Switzerland. Eng. Pat. 115,686, May 15, 1917. (Appl. No. 6943 of 1917.)

ALBUMIN obtained from a normal human or animal organ or tissue, or from the juices expressed therefrom, is so far freed from constituents, such as degradation products, soluble in water, that it no longer gives the ninhydrin reaction, and is then converted into metal combinations as described in Eng. Pat. 110,936 (this J., 1917, 1289) for albumin from modified or infected tissues. The preliminary extraction of soluble matters greatly enhances the therapeutic value of the products, enabling the latter to exert their specific action without injurious secondary effects. Details are given of the process as applied to normal lung, brain, liver, and thyroid tissues.—J. H. L.

Halogen calcium compounds; Process of preparing non-deliquescent water-soluble —. E. Ritsert, Frankfurt. Ger. Pat. 305,367, Sept. 16, 1915. Addition to Ger. Pat. 288,966 (this J., 1916, 423).

INSTEAD of combining calcium chloride with lactose, as in the original patent, calcium bromide or iodide is used, or halogen compounds of calcium are made to react with sucrose or levulose to obtain therapeutic preparations.—C. A. M.

Dimethylaminophenyldimethylpyrazolone; Process for manufacturing readily soluble preparations of —. Farbw. vorm. Meister, Lucius, u. Brüning. Ger. Pat. 305,369, July 8, 1915.

DIMETHYLAMINOPHENYLDIMETHYLPYRAZOLONE (dimethylaminoantipyrine) is soluble in 18 parts of water, but by adding to it an equivalent quantity of ethylurethane a preparation soluble in an equal weight of water is obtained. In this way it is possible to obtain a preparation suitable for subcutaneous injection, the urethane being harmless and only increasing the sedative action.—C. A. M.

Ethanoltrialkylarsonium hydroxides and their salts; Process of preparing —. Chem. Werke Grenzach A.-G., Grenzach. Ger. Pat. 305,772, Jan. 25, 1916.

THERAPEUTICALLY active compounds are obtained by the interaction of glycolhalogen-hydrins with trialkylarsines.—C. A. M.

Acetic aldehyde; Manufacture of —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 115,899, May 22, 1917. (Appl. No. 7378 of 1917.)

A **SILICON-IRON** alloy (containing e.g. 12 to 17% Si) is resistant to boiling dilute sulphuric acid and does not amalgamate with mercury, and is therefore suitable for the construction of apparatus for the manufacture of acetaldehyde as described in Eng. Pat. 105,061 (this J., 1918, 222 A).—L. A. C.

Quinine group; Therapeutically-valuable compounds of the —. P. Hüsey, Assignor to Soc. of Chem. Industry in Basle, Switzerland. U.S. Pat. 1,261,235, Apr. 2, 1918. Date of appl., May 23, 1917.

SEE Eng. Pat. 112,974 of 1917; this J., 1918, 222 A. The compound from quinine and diallylbarbituric acid melts at 128° C., is sparingly soluble in water, easily soluble in ethyl and methyl alcohols and in ethyl acetate, and insoluble in petroleum spirit.

Paraffinum liquidum; Process of making —. H. G. C. Fairweather, London. From H. V. Dunham, Brattleboro, Vermont, U.S.A. Eng. Pat. 116,418, Sept. 4, 1917. (Appl. No. 12,672 of 1917.)

SEE U.S. Pat. 1,240,792 of 1917; this J., 1917, 1125.

Halogen products of hydrocarbons; Apparatus for manufacturing —. B. S. Lacy, Seward, N.J. Assignor to The Roessler & Hasslacher Chemical Co., New York. U.S. Pat. 1,263,906, Apr. 23, 1918. Date of appl., Mar. 31, 1917.

SEE Eng. Pat. 101,708 of 1916; this J., 1917, 1063.

Electrolysis of chlorides [and production of chloro-hydrocarbons]. Manufacture of alkalis [and chloro-hydrocarbons]. U.S. Pats. 1,264,535 and 1,264,536. See VII.

Method of producing catalysts for reduction or hydrogenation purposes and apparatus therefor. Eng. Pat. 107,004. See XII.

Surgical dressing [from beeswax]. Product of beeswax and process of manufacturing the same. U.S. Pats. 1,264,185 and 1,264,186. See XII.

Process for obtaining an extract of proteolytic enzymes. Eng. Pat. 106,504. See XVIII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Colour photography. F. E. Ives, Philadelphia, Pa. U.S. Pat. 1,261,512, Apr. 2, 1918. Date of appl., July 19, 1916.

A **FILM** pack for use in three-colour photography comprises three films sensitised to different parts of the spectrum, the outer ones facing one another and the centre one being on a thin support; the first film is coloured to act as a filter for the other two and the second one acts as an additional filter for the third one. For example, the first film is blue-sensitive and is stained yellow, the second film is green-sensitive on a celluloid support and faces the third, red-sensitive film. The centre film may have a transparent coating on its back to give adherent contact with the first film.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

PATENT.

Pyrotechnic article and method of making same. A. Jedel, New York. U.S. Pat. 1,265,205, May 7, 1918. Date of appl., Apr. 23, 1915.

FINELY powdered potassium chlorate, strontium nitrate, and a fusible gum insoluble in water, are mixed, placed in a mould, and heated to melt the gum and agglomerate the material into a briquette.—W. F. F.

XXIII.—ANALYSIS.

Thermo-regulator for apparatus fitted with a constant water-level. J. Milbauer. Z. anal. Chem., 1918, 57, 162—164.

THE overflow water passes into one limb of a U-tube containing mercury, the other limb containing a floating valve controlling the gas supply. Should the supply of water be interrupted, the float falls and cuts off the supply of gas to the burner. (See also J. Chem. Soc., Aug., 1918.)

—W. P. S.

Gas-holder; Universal —. J. Milbauer. Z. anal. Chem., 1918, 57, 161—162.

THE gas-holder described is constructed so that the gas contained therein is delivered at any desired constant rate and pressure. (See also J. Chem. Soc., Aug., 1918.)—W. P. S.

Refractometer; A differential —. G. A. Shook. J. Ind. Eng. Chem., 1918, 10, 553—554.

AN instrument of the Abbé type, so constructed that two liquids may be examined simultaneously.

Acidimetry of coloured solutions: an application of the pocket spectroscope. A. Tingle. J. Amer. Chem. Soc., 1918, 40, 873—879.

IN using the spectroscopic method of determining the end-point in acidimetric titrations (this J., 117 T), the edge of the absorption band nearer the red end of the spectrum is usually the sharper. With cochineal (25 c.c. of a saturated solution in 50% alcohol) the band extends over nearly the whole of the green on neutralisation. With methyl orange the end-point must always be reached by adding alkali to acid and not *vice versa*, and the indicator must be neutral. As usually prepared it

contains free acid. A neutral indicator is prepared by moistening with dilute hydrochloric acid, evaporating, moistening with dilute ammonia, again evaporating, and dissolving in water; 1 c.c. of a 0.1% solution is used. Laemoid does not give a very sharp end-point, neutrality being marked by a total suppression of the spectrum. With phenolphthalein (0.2 c.c. of a 1% solution), a new band is developed in the green, closely bordering on the yellow, one edge almost coinciding with the "D" line. Rosolic acid (0.2 c.c. of a 1% solution) is well suited to spectroscopic observation, the absorption band broadening abruptly after neutrality is reached. The end-point in the titration of sulphuric acid in presence of copper sulphate, *e.g.*, in electrolytic baths, can be easily determined by the spectroscopic method.

Anions; Detection of —. F. Feigl. Z. anal. Chem., 1918, 57, 135–138.

THE following procedure is proposed for the identification of various acids in a mixture. The substance is boiled with concentrated sodium carbonate solution, or fused with a mixture of sodium and potassium carbonates, the solution is filtered, nearly neutralised with nitric acid, warmed with an excess of solid zinc nitrate, and filtered. The precipitate may contain zinc sulphide, sulphite, phosphate, borate, fluoride, ferrocyanide, ferricyanide, cyanide, molybdate, vanadate, and tungstate. These are identified by drop reactions with various reagents, portions of the precipitate being transferred to a piece of filter paper and treated with a drop of the following reagents:—Acid lead nitrate solution, brown coloration (sulphide); sodium nitroprusside, red coloration (sulphite); acid ferrous sulphate solution, blue-green coloration (ferrocyanide); ferric chloride solution, blue coloration (ferricyanide); stannous chloride solution, yellow or brown coloration (molybdate or tungstate); if sulphides and sulphites are absent, a black coloration with mercurous nitrate indicates cyanide, but if sulphide or sulphite is present, a portion of the precipitate is treated with dilute sulphuric acid in a crucible, the latter is covered with a piece of filter paper moistened with ammonium sulphide, and heated; the filter paper is then treated with a drop of acid ferric chloride solution, when a red coloration indicates the presence of cyanides. Borate is detected by the tumeric reaction and fluoride by the etching test. The filtrate may contain zinc thiocyanate, chloride, bromide, iodide, sulphate, thiosulphate, and sulphite. Portions of the filtrate are tested with the usual reagents for thiocyanate, iodide, bromide, sulphate, and sulphite. Another portion of the solution is then treated with lead nitrate, boiled, and filtered; the precipitate gives a brown coloration with silver nitrate if thiosulphate is present. The filtrate is then treated with nitric acid and silver nitrate, and filtered; chloride and bromide may be identified in the precipitate, and chlorate in the filtrate.—W. P. S.

Chlorine, bromine, cyanogen, and mercuric ions; Volumetric determination of —. E. Votocek. Chem.-Zeit., 1918, 42, 257–260, 271–272.

CHLORIDES in a solution rendered slightly acid with nitric acid may be titrated with standardised mercuric nitrate solution, using 0.06 gm. of sodium nitroprusside as indicator; the end-point of the titration is denoted by the formation of a white turbidity of mercuric nitroprusside. Sulphates, phosphates, and chlorates do not interfere, but the solution must not contain sulphites or nitrites. The results obtained are accurate and the method may be used for the titration of very small quantities of chlorides. Bromides, but not iodides or

fluorides, may also be titrated in the same way with mercuric nitrate solution, and mercury salts and mercury in organic combination, after these have been converted into mercuric sulphate, can be titrated with sodium chloride solution. The sodium nitroprusside is added to the solution of the mercuric sulphate and the sodium chloride solution is run in until the turbid solution becomes clear. Cyanides may also be titrated with mercuric chloride solution. Mercury may be separated from copper by means of sodium nitroprusside. A solution containing cupric and mercuric salts is treated with an excess of sodium chloride and sodium nitroprusside is added; the copper is precipitated as cupric nitroprusside whilst the mercury compound remains in solution. If the sodium chloride is added in the form of a standard solution, the mercury may be determined by titration after the copper compound has been removed by filtration.—W. P. S.

Carbon; Determination of — by the wet method. W. Stepp. Biochem. Zeits., 1918, 87, 135–142.

THE flask in which decomposition takes place is connected with a condenser to hold back the acid. Purification of the sulphuric acid is accomplished by heating the strong acid first with potassium bichromate and afterwards with permanganate. It is difficult to obtain the potassium bichromate, used in destroying the organic matter, free from carbonate. The author prefers a mixture of chromic and sulphuric acids. Finally, when oxidation with the mixture of sulphuric and chromic acids has proceeded for four hours, the apparatus is allowed to cool in a current of air free from carbon dioxide, 10 c.c. of 5% solution of potassium permanganate is added, and the mixture is heated for another hour. (See also J. Chem. Soc., Sept., 1918).—S. B. S.

Carbonates and bicarbonates; Determination of —. Use of litmus and phenolphthalein as indicators. W. Mestrezat. Bull. Soc. Chim., 1918, [iv.], 23, 250–251.

IN the titration of carbonates in cold solutions, using phenolphthalein as indicator, a satisfactory and correct end-point is obtained when the whole of the carbonate is just converted into bicarbonate, if the alkaline liquid is diluted so as not to contain more than 0.07% of sodium carbonate. Similarly total alkalinity may be determined by titration of the cold solution, using litmus as indicator, if the following procedure is adopted. The standard acid is added 1–2 c.c. at a time until a change in the tint of the indicator is just noticeable; then between each successive addition of 0.2–0.3 c.c. of standard acid the liquid is thoroughly mixed and divided into two parts, one part being used as a control and the standard acid added to the other. The end-point is attained when the addition of acid no longer causes a change in tint.

—W. G.

Strontium; Detection of — in the presence of barium by means of calcium sulphate. T. P. Raikow. Z. anal. Chem., 1918, 57, 164–170.

THE solution containing strontium and barium is shaken for 15 secs. with an excess of calcium sulphate solution and then filtered. If strontium is present a turbidity develops in the filtrate; with small quantities of strontium the filtrate may have to be boiled before the turbidity is observed. In cases where only very small quantities of strontium are present the latter may be precipitated together with the barium sulphate; the precipitate should, therefore, be washed several times with boiling water and the filtrate thus obtained tested with barium chloride solution to detect the presence of strontium sulphate dissolved out by the hot water.—W. P. S.

Hydrofluoric acid; Use of — in analysis. N. H. Furman. J. Amer. Chem. Soc., 1918, 40, 895—906.

By the use of an acid fluoride solution, copper may be quantitatively separated from vanadium either by electro-deposition or by the action of hydrogen sulphide. The behaviour of vanadium under these circumstances closely resembles that of tin, tungsten, uranium, and titanium. Acid fluoride solutions of stannic tin give none of the characteristic reactions of stannic tin (see page 413 A) and this fact may be utilised in the analysis of tin alloys. The alloy is dissolved in hot concentrated sulphuric acid and the cold solution poured into water containing hydrofluoric acid. Lead sulphate is precipitated and the filtrate contains copper, antimony (trivalent), stannic tin, and a trace of lead. This is treated with hydrogen sulphide when copper, antimony, and lead are completely precipitated. The filtrate containing the tin is evaporated in a platinum dish until the hydrofluoric acid is removed and the sulphuric acid has begun to fume. The sulphuric acid solution is then poured into a large volume of water, the stannic hydroxide salted out, filtered off, and weighed as stannic oxide. By the addition of boric acid to an acid fluoride solution of stannic tin, the ordinary chemical reactions of the metal are developed, and from such a solution the tin may be quantitatively separated either by the action of hydrogen sulphide or by electro-deposition. Silica, in the form of sodium silicate, produces the same effect as boric acid. The change in the behaviour of acid fluoride solutions of stannic tin on the addition of excess of boric acid is made use of in the separation of the metals of the tin group. A further effect produced by the addition of boric acid is that the acid fluoride solutions have a greatly reduced action on the glass of the containing vessels. (See also J. Chem. Soc., Aug., 1918.)—H. M. D.

Copper; Determination of — by potassium thiocyanate, potassium iodide, and thiosulphate. G. Bruhns. Chem.-Zeit., 1918, 42, 301—302.

The neutral or slightly sulphuric acid solution of the copper salt is treated with potassium iodide and then titrated with thiosulphate solution containing an excess of potassium thiocyanate, using starch solution as indicator, or the copper solution may be titrated with thiosulphate solution containing both potassium iodide and thiocyanate. The use of the latter enables a smaller quantity of potassium iodide to be used, since the cuprous iodide formed reacts with the thiocyanate, yielding cuprous thiocyanate and potassium iodide which reacts with a further quantity of cupric salt. Lead does not interfere with the reaction, but silver and mercury must not be present. The influence of ferric salts, if present in small quantity, may be prevented by the addition of oxalic acid; ferrous salts have no effect.—W. P. S.

Copper; Titration of — with potassium cyanide. M. P. Appleby and K. W. Lane. Analyst, 1918, 43, 268.

In the usual method of titrating copper with potassium cyanide, a sharp end-point is not obtained when the concentration of the copper is much less than 1 gram. per litre. Smaller quantities may be accurately titrated in the form of double carbonates of alkali and copper in presence of excess of sodium carbonate. The copper solution is added to a warm solution containing about 70 grms. of anhydrous sodium carbonate and 50 grms. of sodium bicarbonate per 500 c.c. A standard solution of copper is prepared by dissolving about

0.1 gram. of copper in dilute acid, and adding it slowly, and with constant stirring, to 500 c.c. of the solution of carbonate and bicarbonate. This solution is used for standardising the cyanide solution, as in the ammonia method. The end-point of the reaction is shown by the colour of the solution changing from deep blue, through bluish-purple to grey. (See also J. Chem. Soc., Aug., 1918.)—C. A. M.

Mercury; New method of estimating — by means of zinc filings. M. François. Comptes rend., 1918, 166, 950—952.

The mercury salt, in a finely divided state, mixed with 0.5 gram. of potassium iodide is treated with 1 gram. of zinc filings and 10 c.c. of 2 N sulphuric acid. At the end of half-an-hour a further quantity of zinc and acid is added, and this is repeated at the end of the hour. After 24 hours the liquid is decanted through a filter and the residue washed four times by decantation with water. To it is then added, in portions of 5 c.c. each, 25 c.c. of hydrochloric acid, diluted with its own volume of water, and after 24 hours this is decanted and 25 c.c. of fuming hydrochloric acid is added. After 24 hours the zinc has all dissolved and the mercury has collected into one large globule, which is washed by decantation with water, transferred to a capsule, dried first with filter paper and finally over sulphuric acid in the cold, and weighed. The method is accurate and applicable to all mercury salts, whether soluble or insoluble, except the sulphide. It can be applied to cinnabar if this is first oxidised by 10 c.c. of a solution of bromine (50 c.c.) in a mixture of fuming hydrobromic acid (50 c.c.) and water (50 c.c.), and after 24 hours diluted with 30 c.c. of water, and the free bromine removed by the addition of three lots of zinc filings (1 gram. each) at intervals of half-an-hour, prior to the ordinary treatment with zinc and sulphuric acid.—W. G.

Nickel; Determination of — with α -benzildioxime. R. Strebing. Chem.-Zeit., 1918, 42, 242—243.

PRECIPITATION of nickel with α -benzildioxime and weighing of the dried precipitate (Atack, this J., 1913, 769) gives trustworthy results when dealing with small quantities of the metal. If, however, the amount of the latter exceeds 0.025 gram., the results obtained are too high; a larger quantity of the reagent is required, and owing to its small solubility a portion is thrown out of solution and occluded in the nickel precipitate. To determine relatively large quantities of nickel, the slightly ammoniacal solution of the nickel salt is treated with a small excess of a 0.05% alcoholic α -benzildioxime solution, the mixture heated on a water-bath for 10 mins., filtered while hot, the precipitate washed with hot water, and ignited. The residue of oxide obtained is moistened with nitric acid, again ignited, and weighed.—W. P. S.

Chromium; Estimation of — in presence of iron. K. Schorlemmer. Collegium, 1918, 145—149.

The presence of iron in solutions of chromium salts causes error in the ordinary determination of chromium by thiosulphate. To obviate this, the solutions of chromium salts are oxidised with hydrogen peroxide, allowed to cool, and re-oxidised with a fresh addition of peroxide. The ferric hydroxide is filtered off, dissolved in acid, twice oxidised with peroxide, again filtered off, the filtrate added to the first filtrate, and the total chromium determined in the mixture by means of thiosulphate. If much iron is present, the treatment of the ferric hydroxide must be repeated and the filtrate added to the other two.—D. W.

Manganese; Influence of impure zinc oxide on the determination of —. M. Muller. Stahl u. Eisen, 1917, 37, 257. Rev. Mét., 1918, 15, Extr., 172.

THE purity of the zinc oxide used may appreciably affect the estimation of manganese. The following tests are necessary to reveal the impurities contained. To detect heavy metals, lime and magnesia, 1–2 grms. of the zinc oxide is dissolved in 10–20 c.c. of dilute acetic acid (sp. gr. 1.040). The solution should be quite clear and should still remain clear and colourless after the addition of 20 c.c. of dilute ammonia. It should not change on the addition of ammonium oxalate or sodium phosphate, and any precipitate formed by hydrogen sulphide should be pure white. To detect nitrates 1 gm. is dissolved in 10 c.c. of dilute acetic acid. 2 or 3 drops of an indigo solution (1:1000) and 10 c.c. of concentrated sulphuric acid are added, and the solution shaken well. The blue coloration should not be changed. Arsenic is detected by treating 1 gm. of the oxide with 5 c.c. of stannous chloride, the mixture being well agitated. The colour should not deepen after waiting for 1 hour. To test the indifference of the oxide to potassium permanganate, 30 c.c. of dilute nitric acid is concentrated to 5–10 c.c. and cooled. A paste of the zinc oxide made with cold distilled water is then added until a small excess remains. The mixture is made up to 300 c.c., shaken, and filtered. 100 c.c. of the filtrate is heated to boiling and titrated with permanganate.—F. C. Th.

Arsenic; Simple process for the determination of small quantities of — in dead bodies. H. Fühner. Ber. deuts. Pharm. Ges., 1918, 23, 221–229.

THE organic matter is destroyed by mixing 10 grms. of the material with 5 grms. of potassium permanganate and 10 c.c. of sulphuric acid (1:5), and evaporating to dryness on the water-bath. Then 25 c.c. of concentrated sulphuric acid is added, and also hydrogen peroxide solution, until the mixture is decolorised. It is then transferred to a Kjeldahl flask. 30 c.c. of sulphuric acid is added, and the liquid is heated to boiling over a free flame and then reduced with 5 grms. of ferrous sulphate. When cold, 50 grms. of sodium chloride is added, and the liquid is distilled into 50 c.c. of 1% potassium iodide solution in a conical flask, the mouth of which is protected by a tube filled with glass beads moistened with some of the potassium iodide solution. After distillation, 0.5 gm. of crystallised zinc chloride is added to the distillate and then 10 grms. of zinc. To the mouth of the flask a long upright tube is fitted, packed in the lower part with lead acetate paper and provided at the upper end with a long strip of paper which has been immersed in a solution of mercuric bromide and dried. At the end of an hour, the strip of paper is taken out, and the colour produced compared with a series of standard strips corresponding to from 0.005 mgrm. to 0.5 mgrm. of As_2O_3 .—J. H. J.

Marsh's apparatus [for detection of arsenic]. W. Kirkby. Pharm. J., 1918, 100, 286.

IN using Marsh's apparatus for testing for arsenic risk of explosion may be obviated by interposing a tube loosely packed with cotton-wool between the bottle and the hydrogen jet.—C. A. M.

Molybdenum; Determination of —. O. Binder. Chem.-Zeit., 1918, 42, 255.

IN order to convert molybdenum sulphide completely into molybdic acid, so that the latter can be weighed, the ignited sulphide should be treated with a few drops of concentrated nitric acid, then dissolved in ammonia, re-precipitated with nitric

acid, evaporated, and ignited. The pure white molybdic acid thus obtained is weighed, dissolved in ammonia, and any small quantity of insoluble matter separated and deducted from the weight.

—W. P. S.

Plant ashes; Factors affecting the composition of — with special reference to tobacco. O. D. Roberts. Analyst, 1918, 43, 254–259.

ASH obtained by the usual methods of determining the mineral matter in plants is, as a rule, deficient in carbon dioxide, and to obtain comparable results it is necessary to determine carbon dioxide in the ash and to calculate the results upon an ash free from that constituent and from unburnt carbon. Part of the inorganic chlorine in tobacco is lost during the ignition, whilst the amount of sulphate left in the ash is in excess of that originally present as sulphate in the plant. Hence it is inaccurate to assume that the amounts of sulphate and chlorine in the ash represent the total quantity of sulphur and chlorine present in the plant. To determine the inorganic salts the plant should be extracted with water or dilute acids and the salts determined in the extracts, whilst organic chlorine, sulphur, and phosphorus may be obtained by the difference between the results for the total and the inorganic constituents.—C. A. M.

Gas analysis with very small quantities. L. Hamburger and W. Koopman. Z. anal. Chem., 1918, 57, 121–135.

AN apparatus is described by means of which very small quantities of gaseous mixtures may be analysed, and in which, during the analysis, the gas comes in contact only with glass, platinum, and mercury. The gas is freed from moisture and carbon dioxide by cooling with a mixture of solid carbon dioxide and alcohol and with liquid air respectively, then burnt by means of a platinum spiral, after addition of oxygen or of hydrogen if necessary; excess of unburnt oxygen is determined by adding hydrogen and again burning, the use of an iron spiral having proved unsatisfactory. A capillary tube is used for the combustion, as if this be effected at a low pressure combination of nitrogen and oxygen and of oxygen and mercury vapour may occur and lead to incorrect results. The use of automatic pumps of the Sprengel type for transferring the gas from one part of the apparatus to another is also inadmissible, as gas occluded by the mercury is liberated when the pressure falls very low and may pass into the measuring tube. The use of Töppler pumps overcomes this difficulty. Results obtained with quantities of gas of the order of 10 cb.mm. are given. In the case of a mixture of H_2 26.7, CO 22.7, CH_4 22.9, and N_2 27.8%, the values found were H_2 26.4, CO 21.1, CH_4 21.2, and N_2 28.3%.

PATENTS.

Thermo-elements having copper sulphide as the positive constituent; Process for the manufacture of —. J. Marschall, Dresden, Germany. Eng. Pat. 103,671, Jan. 25, 1917. (Appl. No. 1277 of 1917.) Under Int. Conv., Dec. 9, 1915.

A SMALL proportion (1–3%) of sulphur is added to the copper sulphide, before casting, to increase the mechanical strength and reduce the specific resistance without appreciably affecting the E.M.F. of the material. The contact points of the casting are surrounded by a layer of electro-deposited metal which serves as a support for the attachment of other metallic parts of the element.—W. E. F. P.

Gas; Apparatus for analysing —. Aktiebolaget Ingeniörsfirma F. Egnell, Stockholm. Eng. Pats. (A) 103,812, Sept. 27, 1916, and (B) 104,160, Sept. 28, 1916. (Appl. Nos. 13,749 and 13,800 of 1916.) Under Int. Conv., Jan. 29 and Feb. 12, 1916.

(A) In an apparatus applicable for analysing flue gases, the gas is drawn through a liquid seal into a measuring vessel by the withdrawal of liquid from the latter, and is forced out through another liquid

seal as the liquid again rises, to a pipe having two branches, one of which dips into an absorption receptacle containing caustic potash for absorbing carbon dioxide, and the other passes to a receptacle containing pyrophoric iron for absorbing oxygen. The outlet pipes from these two receptacles are combined and discharge into another measuring vessel. When a valve on the pipe leading to the absorbing receptacle for oxygen is closed, the gas passes only through the caustic potash to the second measuring vessel, so that the volume of carbon dioxide is obtained. When the valve is opened the caustic potash acts as a liquid seal, and the gas passes only through the oxygen-absorbing receptacle to the second measuring vessel thus indicating the volume of oxygen. In a modification, the outlet pipes from the two absorbing receptacles are not connected to the second measuring vessel, but an auxiliary receptacle is provided communicating with the receptacle containing caustic potash into which the liquid is forced, and the increase of pressure is measured to give an indication of the volume of gas absorbed. The first measuring vessel may also be divided into two similar vessels, from which the gas is passed to the two absorbing vessels respectively. In another modification, the control valve is provided on the pipe leading from the oxygen-absorbing vessel and controls the passage of gas from this receptacle to the measuring vessel, or to the absorbing vessel for carbon dioxide. Several other combinations of two or more absorbing receptacles are also described. (B) In apparatus of the type described in (A) in which the gas has to be chemically or physically treated before analysis, a constriction is provided in the gas inlet piping, or in the discharge pipe of the medium which causes the flow of gas into the first measuring vessel, so as to retard the flow of gas.—W. E. F. P.

Gas calorimeter. J. F. Simmance, London. Eng. Pat. 115,915, May 31, 1917. (Appl. No. 7813 of 1917.)

In a recording, constant flow gas calorimeter, the container through which the gas passes on its way to the burner is so constructed and adjusted that the gas issues from the burner orifice at a standard volume per unit time, irrespective of changes due to variations in temperature, pressure, and specific gravity. The gas on its way to the calorimeter may be by-passed through a wet meter, and the recording pen adjusted to correspond with the calorific value determined in the usual manner, the gauge-glass of the meter being connected, through a tap, with a water reservoir adapted to be raised or lowered, to facilitate adjustment of the water level. To ensure regularity of flow and constant pressure of water at the entrance to the calorimeter, the water supplied at constant head is consecutively exposed to the atmosphere in three or more vessels at successively lower levels, each forming a constant head, and the last being within the calorimeter. Provision is also made for saturating with aqueous vapour the air supplied for combustion, and for cutting off the gas supply automatically in the event of the flow of water being interrupted.

—W. E. F. P.

Distillation; [Laboratory] apparatus for fractional —. S. E. Bowrey, London. Eng. Pat. 115,504, May 15, 1917. (Appl. No. 6939 of 1917.)

In an apparatus for fractional distillation the supply of gas for heating is controlled by a thermo-regulator of known type containing mercury, actuated directly by the pressure of the vapour in the distillation column. The mercury tube of the regulator is sealed through the wall of the column and bent upwards inside, below the level of the side tube leading to the condenser. To ensure a sufficient pressure of vapour to actuate the regulator

properly, the passage of vapour up the column may be obstructed by a constriction above the level of the regulator tube but below that of the condenser tube; the portions of the column above and below the constriction may be connected externally by a reflux tube of suitable length, to allow any liquid condensed above the constriction to flow back into the lower part of the column.—J. H. L.

Densimetric methods and appliances. A. F. C. Pollard, Ardrossan. Eng. Pat. 115,062. (Appl. Nos. 6480, May 7, and 18,174, Dec. 7, 1917.)

In order to indicate or record the density or temperature of a flowing liquid or to separate a flowing liquid into fractions of varying densities, the liquid is caused to flow through a movable system supported by hydraulic means on a fixed axis of rotation in such a manner that the supply and discharge of the liquid have no turning effect on the movable system, but the latter assumes a definite angular position of stable equilibrium which varies with and corresponds to the density and/or temperature of the liquid. A liquid of standard density of the same kind as, or having a coefficient of expansion approximately the same as, that of the other liquid, is caused to flow through the system in a similar manner in order to eliminate the effect of temperature on the density. The apparatus may be used in conjunction with a spirit still, and the effect of the varying density of the distillate on the angular position of the movable system may be utilised to collect fractions of different densities in separate receivers. Various forms of the apparatus are described and illustrated in detail.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Barron and Barron. Impact grinders. 11,059. July 5.
 British Dyes, Ltd., Turner, and West. Tanks for transporting hydrochloric acid or other corrosive liquids. 11,781. July 18.
 Fraser. Machines for disintegrating and screening pulverulent material. 11,730. July 17.
 Hall. Grinding machinery. 11,970. July 23.
 Hayhurst. Drying machines. 11,797. July 18.
 Hill and Tuckett. Grinding apparatus. 12,009. July 23.
 Levinstein, Oxley, and Levinstein, Ltd. Process for carrying out catalytic reactions. 12,027. July 23.
 Lynde. Digesters. 12,034. July 24.
 Mansfield. Filters for liquids. 11,155. July 8.
 Morison. Condensing-plant. 11,242. July 9.
 Preisig and Steiger. Drying finely-divided material. 10,998. July 4.
 Stuart. Reclaiming material. 11,462. July 12. (U.S., Nov. 13, 1917.)
 Sturgeon. Centrifugal separators. 11,818. July 19.
 Techno-Chemical Laboratories, Ltd., and Testrup. Conducting high temperature reactions. 10,939. July 3.
 Topham. Furnaces. 11,911. July 20.
 Ward and Ward. Centrifugal separators. 11,392. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

- 18,409 (1916). Trottier. Apparatus for sorting or separating solid substances. (117,274.) July 24.

- 5004 (1917). Hamilton (Allan). See II.
 5263 (1917). Carr. Method of drying liquid materials. (117,469.) July 31.
 7467 (1917). Clifford, and Jones and Attwood. Separation and settlement of solids and semi-solids from chemical and like manufacturing liquids. (117,472.) July 31.
 7589 (1917). Miller and Lloyd. Grinding or crushing machines. (117,281.) July 24.
 7941 (1917). Roy, and Morson and Son. Method and means for bringing about chemical reactions between gases and/or vapours by means of catalysts. (117,103.) July 17.
 9466 (1917). Barbet et Fils et Cie. See XVIII.
 10,114 (1917). Ges. f. Linde's Eismaschinen A.-G. See VII.
 11,059 (1917). British Dyes, Ltd., Turner, and Crosland. Grinding mills, disintegrators, mixers, etc. (116,958.) July 10.
 12,072 (1917). Fritzweiler and others. See X.
 12,475 (1917). Wood. Centrifugal apparatus for extracting dust from air or gases. (117,173.) July 17.
 12,592 (1917). Brand. Furnace rakes for mechanical roasting-furnaces and the like. (116,974.) July 10.
 16,592 (1917). Benjamin. Continuous tunnel kilns. (117,383.) July 24.
 16,976 (1917). Leitch. Apparatus for solidifying or concentrating liquid or semi-liquid materials on a revolving cylinder. (117,560.) July 31.
 18,239 (1917). Wurth. Charging shaft-furnaces. (117,024.) July 10.
 1734 and 4993 (1918). Simon-Carves, Ltd., and Hunter. Settling-tanks for clarifying liquids. (117,576 and 117,586.) July 31.
 3385 (1918). Stokes. Incinerating-furnaces. (117,417.) July 24.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- American Linseed Co. Artificial fuel and methods of making same. 11,741. July 17. (U.S., July 17, 1917.)
 American Linseed Co. Apparatus for producing artificial fuel, etc., from plastic or viscous material. 11,742. July 17. (U.S., July 17, 1917.)
 Campion. Gas-producers. 11,969. July 23.
 Coke Oven Construction Co., Colquhoun, and Marr. Coke ovens, etc. 11,256 and 11,257. July 9.
 Davies. Distillation, gasification, etc., of carbonaceous material. 10,895. July 3.
 Davies. Carbonisation of wood, etc. 11,898. July 20.
 Davies. Carbonisation of carbonaceous materials. 11,602. July 16.
 Dempster and Sons, and Toogood. Distillation of coal. 11,610. July 16.
 Flood and Flood. Quenching coke. 10,914. July 3.
 Holt. Manufacturing gas from coal, etc. 10,972. July 4.
 James. Burning-fuel. 11,012. July 4.
 Johnson (Houghton and Co.). Manufacture of cutting oils. 11,581. July 15.
 Lamplough. Converting heavier hydrocarbons into lighter hydrocarbons. 11,808. July 18.
 Leadbeater. Treating peat to render it more adaptable as fuel. 10,823. July 2.
 Lloyd. Preparation of fuel oil from dehydrated tar. 12,192. July 25.
 McCaffery. Generating gaseous fuel for heating or firing furnaces. 11,989. July 23.
 Macrae and Topp. Manufacture of fuel from peat, lignite, etc. 12,040 and 12,041. July 24.
 Milbourne. Gas purifiers. 11,453. July 12.

Mitchell. Furnaces for treating briquetted fuel. 10,813. July 2.

Oddy and Smith. Distillation of coal, shale, peat, wood, etc. 11,356. July 11.

Oddy and Smith. Purifying or refining hydrocarbons. 11,357. July 11.

Oddy and Smith. Light hydrocarbons for motor and lighting purposes. 11,358. July 11.

Oré. Purification of coal gas and manufacture of iron salts used in same. 11,677. July 16.

Parkes and Pearson. 11,397. *See* XX.

Pease. Heat treatment of coal to obtain oils, gas, ammonia, etc. 12,207. July 26.

Rew. Manufacture of gas. 11,318. July 10.

Spicer (Wells and Wabba). Gas-producing and gas-purifying devices. 11,309. July 10.

Wade (Pittsburgh Testing Laboratory). Process of regenerating lubricants. 11,402 and 11,407. July 11.

Wallace. Utilisation of oil, etc., shales. 12,250. July 27.

West and Wild. Retorts for destructive distillation of coal, etc. 11,738. July 17.

Wolstencroft. Utilisation of waste material for artificial fuel. 10,953. July 4.

COMPLETE SPECIFICATIONS ACCEPTED.

9178 (1916). Cassal, Cassal, and Gerrans. Treatment of liquid hydrocarbon. (117,087.) July 17.

5004 (1917). Hamilton (Allan). Continuous fractionation and dephlegmation of petroleum or other hydrocarbon distillates or mixtures of volatile liquids. (117,277.) July 24.

9485 and 9487 (1917). Jackson (Seaman Waste Wood Chemical Co.). Distillation of wood, etc. (116,939 and 116,940.) July 10.

10,224 and 12,043 (1917). Helps. Manufacture and treatment of coal or like gas. (117,308.) July 24.

15,654 (1917). Forward. Production of motor fuel oil by distilling petroleum. (117,372.) July 24.

17,165 (1917). Hemingway. *See* VII.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Ambler, Gibbs, and Selden Co. Production of sulphonic acids. 11,196. July 8.

Cooper. Preparation of β -naphthol. 11,896. July 20.

Gibbs, Lewis, and Selden Co. Purification of anthraquinone. 11,072. July 5.

Lewis. Production of monochlorobenzol. 11,706. July 17.

Lloyd. 12,102. *See* II.

Lord. Obtaining products from blast-furnace pitch. 11,745 and 12,193. July 17 and 26.

Valentine. Apparatus for dehydration and fractional distillation of coal tar, etc. 11,163. July 8.

COMPLETE SPECIFICATIONS ACCEPTED.

4430 (1917). Cooper and Edwards. Production of high-boiling phenols. (116,905.) July 10.

5004 (1917). Hamilton (Allan). *See* II.

9101 (1917). Inray (Soc. Chem. Industry in Basle). Manufacture of derivatives of *p*-amino-phenol. (116,920.) July 10.

16,653 (1917). Ellis and others. *See* XIII.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Brotherton and Co., Ehrhardt, and Kay. Manufacture of black sulphur colours. 11,215. July 9.

Holliday and Co., and Law. Chlorination of purpurin, etc. 10,787. July 2.

Holliday and Co., and Law. Chlorination of alizarin and its derivatives. 10,788. July 2.

Inray (Soc. Chem. Industry in Basle). Orthoxy-azo dyestuffs, chromium compounds, and process of dyeing therewith. 11,458. July 12.

Marks (Sunbeam Chemical Co.). Universal dyes and method of producing same. 11,078. July 5.

Soc. L'Air Liquide. Manufacture of a blue sulphurised dye. 11,949. July 22. (Fr., July 31, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

200 (1917). Oman. Preparation of azo colouring matters from lignonsulphonic acid or its salts. (103,480.) July 31.

4856 (1917). Malcolmson and Fitzgerald. Manufacture of dyestuffs and process of dyeing therewith. (117,095.) July 17.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Auchinachie. Treatment of cardboard to render it impermeable. 12,052. July 24.

Bacon and Sindall. Treatment of straw, bracken, etc., to manufacture paper pulp. 11,945. July 22.

Barr. 10,862. *See* XIII.

Bindley and Dulcken. 11,759. *See* XIII.

Dreyfus. Manufacture of cellulose derivatives. 11,872 and 11,873. July 20.

Dreyfus. Manufacture of dopes, solutions, or preparations having a basis of cellulose acetate. 12,085. July 24.

Dunville and Co., and Gilmour. Production of solvents for cellulose acetates and nitrates, including celluloid, and their use in the production of varnishes, lacquers, and dopes. 10,949. July 4.

Flatters. Rendering fabrics gas- and water-proof. 11,607. July 16.

Flatters. Process for doping and fireproofing fabrics. 11,608. July 16.

Higgins. Manufacture of paper from seaweed. 11,561. July 15.

Johnston and Sutherland. Degumming and cleansing or bleaching leaf and stalk fibres. 11,506. July 13.

Lancaster. Treating paper or cloth articles with paraffin waxes, etc. 11,767. July 18.

McEwen. Treatment of flax, etc. 12,113. July 25.

Milne. Paper-making machines. 10,985. July 4.

Partington and Roberts. Pulp for making paper, etc. 11,282. July 10.

Peachey. 11,267. *See* XIII.

Schweizerische Versuchsanstalt für Textilindustrie. Testing textile, etc., materials. 11,303. July 10. (Switz., Mar. 13.)

Soc. Nauton Frères et de Marsac, and Tesse. 11,007. *See* XIII.

COMPLETE SPECIFICATIONS ACCEPTED.

200 (1917). Oman. *See* IV.

7569 (1917). Davies. Fourdrinier paper machines. (107,579.) July 31.

805 (1918). Schmid. *See* XII.

3235 (1918). Rafsky. Coated paper. (117,414.) July 24.

5958 (1918.) Galloway and Stratton. Apparatus for colouring paper. (117,428.) July 24.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Ainsworth and Mather. Winding and dyeing machines. 11,427. July 12.

Clavel. Dyeing, bleaching, etc., cops. 11,665. July 16. (Ger., July 20, 1917.)

Inray (Soc. Chem. Ind. in Basle). 11,458. *See* IV.

COMPLETE SPECIFICATIONS ACCEPTED.

4856 (1917). Malcolmson and Fitzgerald. *See* IV.

566 (1918). Glaister and Hoyle. Dyeing textile fabrics, and apparatus therefor. (117,039.) July 10.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Bousfield, and Nobel's Explosives Co. Manufacture of liquid nitrogen peroxide and nitric acid. 10,869. July 2.

Brace. Pyrites furnaces. 11,020. July 4. (Fr., Feb. 22, 1917.)

British Dyes, Ltd., Turner, and West. 11,781. See I.

British Thomson-Houston Co. (General Electric Co.). 12,195. See X.

Dutt and Dutt. Manufacture of sulphur, alkaline earth carbonates, and alumina. 11,293. July 10.

Fitzgerald. Preparation and use of dense poisonous gases other than chlorine for military purposes. 11,570. July 15.

Jephcott. 11,637. See XX.

Norsk Hydro-Elektrisk Kvaestofaktieselskab. Production of ammonia from cyanamide. 12,000. July 23. (Norway, Oct. 4, 1917.)

Norsk Hydro-Elektrisk Kvaestofaktieselskab. Production of alumina compounds from clay, argillite, etc. 12,001. July 23. (Norway, Sep. 25, 1917.)

Norton Co. Purifying aluminous materials. 11,378. July 11. (U.S., Aug. 18, 1917.)

Norton Co. Producing crystalline alumina. 11,379. July 11. (U.S., Aug. 18, 1917.)

17,165 (1917). Hemingway. Desulphurisation of gases and other fluids containing sulphuretted hydrogen. (117,387.) July 24.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Forster. Feeding or controlling feed of molten glass from glass furnaces or tanks. 12,093. July 25.

Hill and Manby. Polishing or grinding composition. 11,802. July 18.

Norton Co. 11,379. See VII.

Norton Co. Aluminous abrasive. 11,380. July 11. (U.S., Dec. 26, 1917.)

Roberts, Thomas, and Williams. Manufacture of tiles, bricks, and coarse ware. 11,889. July 20.

COMPLETE SPECIFICATIONS ACCEPTED.

10,257 (1917). Bennett. Kilns for firing earthenware, tiles, and other articles. (117,147.) July 17.

15,735 (1917). McCoy. Apparatus for manufacture of sheet glass. (117,194.) July 17.

16,592 (1917). Benjamin. See I.

2579 (1918). Edwards, Edwards, and Mollart.

Glaze used in manufacture of pottery and like articles. (117,047.) July 10.

8003 (1918). Kettel, Gasch, and Dean. Method for platinising earthenware, pottery, etc. (117,432.) July 24.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Akerman. Manufacture of Portland cement. 10,801. July 2.

Gastaldo and Mine. Artificial stone. 11,957. July 22.

Hoare. Production of building-material. 10,937. July 3.

Otto. Seasoning wood. 11,904. July 20.

Patentaktiebolaget Jungners Kali-Cement. Simultaneous manufacture of hydraulic cement and alkali. 11,369. July 11. (Sweden, July 11, 1917.)

Revello. Cementing substance. 10,878. July 2.

Roberts and others. 11,889. See VIII.

COMPLETE SPECIFICATIONS ACCEPTED.

10,690 (1917). Stewart. Concrete and the like. (117,504.) July 31.

12,116 (1917). Kiefer. Bricks or building blocks. (110,155.) July 24.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Aktiebol. Svenska Kullagerfabriken. Hardening process. 10,886. July 2. (Sweden, June 18, 1917.)

Ashcroft. Manufacture of magnesium and calcium metals and alloys. 10,808. July 2.

Ballantine and Sulman. Production of ferro-alloys. 10,819. July 2.

Berglund. Extraction of zinc in electric furnaces. 12,219. July 26. (Sweden, Oct. 22, 1917.)

British Thomson-Houston Co. (General Electric Co.). Methods of producing pure elements. 12,195. July 26.

Broadley. Machines for separating metals, ores, minerals, etc., by settlement and flotation. 10,828. July 2.

Brown, and Simon-Carves, Ltd. Crucible and melting-pot furnaces. 10,893. July 3.

Bruuskill. Coating duralumen and aluminium sheets, wires, etc., with non-corrodible layer of copper or compound of copper with a sodium aluminate or both. 10,820. July 2.

Bullen. Concentration of ores. 11,140. July 6.

Cliff. Puddling, reheating, and like metallurgical furnaces. 11,553. July 15.

Elmore. Extraction of lead from its ores. 11,126. July 6.

Evans. Means for separating magnetic material. 11,940. July 22.

Hadfield. Manufacture of iron-silicon alloys. 10,924. July 3.

Hadfield. Manufacture of low-carbon ferro-manganese. 11,198. July 8.

Lalbin. Obtaining by a cold process a galvanic deposit of aluminium. 11,115. July 5.

Lord. 11,745 and 12,193. See III.

Marino. Process for electroplating metals, particularly for coppering iron and steel. 12,125. July 25.

Mooney. Treating steel for aircraft. 11,148. July 8.

Moysey. Prolongs used in the production of zinc or spelter. 11,678. July 17.

O'Gorman and Thomas. Indicating the condition of steel, etc., under heat treatment. 11,002 and 11,003. July 4.

Pope and Thomas. Indicating the condition of steel and other magnetisable metal under heat treatment. 11,104. July 4.

Rigg. Desulphurisation of zinc sulphide ores. 11,588. July 15. (Australia, Sep. 18, 1917.)

Rouvier. Uniting aluminium or aluminium alloy members to other members. 11,249. July 9.

See, Herme et Bulre. Treatment of iron ore and ferrous materials in a pulverulent condition. 11,332. July 10. (Fr., July 10, 1917.)

Stabilimentl Blak. Ing. Pouchain. Light alloy for parts subjected to high temperatures. 11,946. July 22. (Ital., Mar. 2.)

Stabilimentl Blak Ing. A. Pouchain. Manufacture of aluminium alloy. 11,947. July 22. (Ital., Mar. 22.)

Sumitomo Chukosho, Ltd. Magnet steel. 10,834. July 2. (Japan, July 10, 1917.)

Turner. Granulating and disintegrating aluminium, etc. 12,037. July 24.

Welford. Treatment of aluminium compounds to produce aluminium, metals, salts, etc. 12,232. July 27.

COMPLETE SPECIFICATIONS ACCEPTED.

15,385 (1916.) Riedel. *See* VII.

5298 (1917.) Herreshoff. Recovery of values from metalliferous slags. (117,470.) July 31.

8175 (1917.) Greaves and Etchells. Manufacture of steel. (117,286.) July 24.

9674 (1917.) Queneau. Separation of metals from their ores. (116,943.) July 10.

9736 (1917.) Wust. Method of improving the Thomas process. (107,770.) July 10.

9756 (1917.) Lancey. Crucible furnaces. (116,946.) July 10.

10,061 (1917.) Inman. Gas-heated and similar furnaces for heat-treating metals and the like. (117,301.) July 24.

I.—GENERAL ; PLANT ; MACHINERY.

Filters; New — R. Zsigmondy and W. Bachmann. *Z. anorg. Chem.*, 1918, **103**, 119—128.

A new type of filter, termed a membrane filter, is prepared by drying solutions of certain colloids, under conditions not specified. The filters have a parchment-like appearance with a smooth surface, and it is claimed for them that they are strong, durable, and rapid. The size of the pores can be varied, and suitable membranes chosen for any desired purpose. The filters are specially suitable for filtering under reduced pressure, and an advantage is that after use they can be cleaned and used again with undiminished filtration velocity. They have been used successfully for filtering gold and graphite sols, and for separating mixed colloidal solutions containing particles of different sizes. (See also *J. Chem. Soc.*, Sept., 1918.)

—E. H. R.

PATENTS.

Purifying or otherwise conditioning air or other gases; Apparatus suitable for — and for other purposes. C. E. Jeffcock and W. H. Yardley. *Sheffield. Eng. Pat.* 116,512, Mar. 20, 1917. (Appl. No. 4055 of 1917.)

A SERIES of vertical parallel plates with horizontal corrugations is arranged in a casing with the crests of adjacent plates opposed, and liquid is allowed to drip on to the plates from a superposed chamber with a perforated bottom. The liquid flows in thin films over the plates and is collected in a sump from which it may be drawn by a pump for further circulation. The gas passes horizontally through the casing, and blades twisted helically are clamped between the corrugations to cause rotation of the streams of gas and ensure better contact with the wet plates. The diameter of the twisted blades is such that the opposed crests of the corrugated plates are spaced a short distance apart. The helical blades are arranged in two sets, separated by a free vertical space, and the liquid is caused to flow only over the plates at the air inlet end, covering one of the sets of blades. The treated gas expands on reaching the intermediate space and then passes through the spaces containing the other set of helical blades so that entrained moisture is deflected on to the plates and drains into the bottom of the casing. On leaving the plates, the treated gas may impinge on a layer of asbestos, felt, or other absorbent material to eliminate moisture before passing from the apparatus. In a modification, the suction pipe from the sump is provided with a strainer, and the superposed liquid-supply chamber is provided with a series of horizontal superposed perforated plates to distribute the liquid.—W. F. F.

Mixing gases and liquids; Process for — M. Bruman. *Berlin. Ger. Pat.* 304,042, Jan. 6, 1915.

THE gas and liquid are forced separately into a chamber in which two turbine wheels rotate, one fixed and the other loose on the same axle, the former being coupled to a motor. The fluids are thoroughly mixed first in the inner and then in the outer turbine wheel and impelled by centrifugal force to the periphery, where they are collected by a pipe of trumpet shape, which delivers them into a receiving tank. The contents of the latter can be drawn through the apparatus again.

—H. J. H.

Spraying liquids into gases; Apparatus for — E. Enke. *Breslau. Ger. Pat.* 304,050, May 31, 1916.

A JET is employed consisting of two cylindrical concentric tubes, the outer projecting beyond the

inner. The liquid is supplied through the inner tube and breaks into spray in consequence of the partial vacuum induced by the gas forced through the outer tube. No high pressures are required.

—H. J. H.

Grinding ores, minerals, stones and the like; Machines for — J. R. Broadley, *London. Eng. Pat.* 116,583, July 13, 1917. (Appl. No. 10,145 of 1917.)

THE material is ground in the ordinary way in a horizontal cylinder, *a*, provided with grinding balls, and then passes through a grid plate, *j*, into the compartment, 17, bounded by a perforated screen.

The finished material which passes through is collected by the shoots, *c*, which are partly radial and partly spiral, and is discharged through the passages, 19, to the conduits, 15, and outlet, *f*, in the hollow trunnion, *d*. The material which does not pass through the screen, 17, is returned by the radial guides, *z*, and passages, 20, to the cylinder, *a*, for re-grinding. In a modification two concentric screens are used; the material retained by the inner screen is returned by radial guides through the hollow trunnion to the grinding cylinder; the material retained by the outer screen is discharged axially at its open end into a hopper; and the fine material passing through both screens falls into another hopper. In a modification of the latter machine, a single screen only may be used.

—W. F. F.

Drying apparatus for use in drying fruit, herbs, vegetables, seeds, chemicals, fibre, and the like. C. S. Boulton, Broughton, Northants. *Eng. Pat.* 116,606, Aug. 16, 1917. (Appl. No. 11,795 of 1917.)

HOT air is passed over the material contained in shallow trays, which are arranged one above the other on platforms in a frame, and are provided with gauze bottoms. Two opposite sides of each tray project below the gauze bottom in the form of an obtuse-angled V, so that the tray may be tilted to one side or the other and the under and upper sides exposed alternately to the current of hot air. The air passes upwards at one side of

the tier of trays, and then horizontally over and through the trays. The inlet of each compartment containing a tray is provided with a baffle extending downwards from the upper edge so that by moving the tray to or from the opening and retaining it by means of a wedge, and by tilting it, the admission of air may be varied or stopped. The outlet from any compartment may be controlled or closed by a board or flap when a tray is or is not in use in that compartment.—W. F. F.

Desiccating liquid substances; Process and apparatus for —. C. E. Gray, Eureka, Cal. U.S. Pat. 1,266,013, May 14, 1918. Date of appl., Sept. 30, 1915.

THE drying chamber has the form of an inverted cone, and the liquid is sprayed on to the inner wall of the chamber by a rotary sprayer. A cyclonic air current is created through the chamber and over the drying surface for causing the particles of substance to move toward and remain near the drying surface when detached from it. The moisture is carried away by the air current, and the solid substance is mechanically detached from the surface and moved along to the discharge outlet by a scraper which travels in advance of the sprayer.—J. H. P.

Dryer; Revolving cylindrical —. L. F. Baier, Ravensburg, and F. Baier, Kempen. Ger. Pat. 303,016, Sept. 4, 1915.

THE dryer consists of a revolving cylinder fitted with longitudinal ribs bearing attachments arranged to throw the material backwards. Between the ribs are the blades of a screw conveyor which carries the material forward. The ribs are connected to a plate at the end of the cylinder, which is geared to move backwards and forwards and which communicates this motion to the ribs themselves.—H. J. H.

Dryer; Tubular — for lignite, etc. Zeitzler Eisengiesserei und Maschinenbau A.-G., Zeitz. Ger. Pat. 304,081, Dec. 31, 1913.

THE dryer consists of a horizontal cylinder containing a perforated central tube of large diameter, surrounded by other tubes, and the heating is effected by steam blown into the central tube and escaping by an outlet at the periphery. The outlet is connected by a system of pipes fitted with steam traps to the fresh steam injector, whereby the exhaust steam, after separation of condensed water, is returned to the dryer. The distribution of steam through the perforations of the inner tube can be controlled.—H. J. H.

Evaporator. W. G. Abbott, jnn., Wilton, N.H. U.S. Pat. 1,265,863, May 14, 1918. Date of appl., Jan. 13, 1915.

THE apparatus comprises a series of pairs of concentric tubes, with means for circulating a fluid through the annular spaces between the tubes. A member fitting over the end of each inner tube has an outwardly flaring surface in order to deflect outwardly the fluid issuing from the annular space. Radial spacing fingers are arranged between the tubes.—J. H. P.

Evaporator. A. E. Hammond, Portland, Oreg. U.S. Pat. 1,266,461, May 14, 1918. Date of appl., May 21, 1917.

A LONG rectangular housing is provided with an air inlet and means for heating the air at one end.

At the opposite end the end walls converge and means are provided for circulating the air through the housing. Near the ends are curved partitions to distribute and retard the flow of the air. The material to be dried is carried through the housing in cars, which travel on longitudinal and transverse tracks, with turntables at the junctions.

—J. H. P.

Filter; Continuous rotary pressure —. J. A. McCaskell, Salt Lake City, Utah. U.S. Pat. 1,266,133, May 14, 1918. Date of appl., Apr. 18, 1917.

THE material to be filtered is admitted to a closed pressure chamber within which rotates a shaft having a series of hollow filtering elements attached to it. These filtering elements and the shaft have connecting filtrate passages. Fixed scrapers extend transversely to the shaft and remove solids deposited on the filters. The material scraped off the filters is collected in transverse troughs which are connected with a main trough inside the casing, parallel to the shaft. This latter trough is provided with a conveyor for removing the material.

—J. H. P.

Emulsifier. M. Leitch, Poughkeepsie, N.Y., Assignor to The De Laval Separator Co., New York. U.S. Pat. 1,266,501, May 14, 1918. Date of appl., June 14, 1915.

A ROTARY emulsifier comprises a central receiving chamber in the upper end of a vertical shaft and communicating by passages with an annular sediment collecting chamber. Above the latter and surrounding the receiving chamber are one or more emulsifying elements. The emulsifying elements have inlet passages leading from the sediment chamber and outwardly extending distributing passages terminating in emulsifying discharge orifices.—J. H. P.

Stopper for carboys or the like. British Dyes, Ltd., J. Turner, J. Bruce, and J. D. Eastwood, Huddersfield. Eng. Pat. 116,798, July 30, 1917. (Appl. No. 10,908 of 1917.)

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Errors in ultimate analysis of — due to the presence of carbonates. Knublauch. J. Gasbeleucht., 1918, 61, 183—186.

A study of twelve analyses shows that the error due to carbon dioxide liberated from alkaline-earth carbonates (this J., 1916, 295) may be considerable, e.g., 1% in the percentage of carbon, and also that it bears no relation to the ash content. In the proximate analysis of coal this carbon dioxide alters the character of the volatile matter, and consequently should be allowed for in the value of the factor, V, in Goutal's formula for calculating the calorific value.—H. J. H.

Coal; Comparative study of the thermal decomposition of — and of some of the products of its carbonisation. M. C. Whitaker and J. R. Suydam, jun. J. Ind. Eng. Chem., 1918, 10, 431—432.

Comparative experiments were made by decomposing powdered Pennsylvania gas coal, gasoline, kerosene, gas oil, benzene, and naphthalene at different temperatures, ranging from 650° to 900° C., in a vertical, electrically heated furnace consisting of an iron tube, 6 ft. long and 4 in. in diameter, and conducting the gases from the bottom of the furnace to a gas-holder. The coal was dropped from a hopper through the heated tube, whilst the other substances were vaporised by allowing them to trickle down a length of chain suspended in the upper part of the furnace. It was found that the paraffin hydrocarbons when thus "cracked" at the same temperature yielded gases of practically the same composition, whereas the aromatic hydrocarbons without side chains only began to decompose at a higher temperature than the paraffins and apparently yielded only hydrogen and methane on decomposition. Eliminating constituents containing nitrogen and oxygen, the coal gas was similar to that obtained from the paraffin oils and unlike that produced from the aromatic substances. Hence the conclusion is drawn that in general coal is composed of straight-chain compounds.—C. A. M.

Wood and peat; Manufacture of gas from — in the municipal gasworks at Horsens, Denmark. J. Qvist. J. Gasbeleucht., 1918, 61, 193—195.

The shortage of coal in 1917 necessitated the carbonisation of wood and peat—the latter after a certain degree of drying in stacks. Horizontal hand-fired retorts were used and a certain amount of coal was carbonised, but separately from the substitutes. The charge of wood or peat was 55—60 kilos. per retort and the make of gas 30 cub. metres per 100 kilos. Trouble occurred owing to accumulations of pitch in the hydraulic main. The gas contained 23—25% CO₂ and had a gross calorific value of 3700—4000 kilogram-calories per cub.

metre. On distribution of the gas there was an increase of trouble due to naphthalene stoppages. The yield of ammonia was small, but the admixture of a proportion of coal gas sufficed to neutralise the acetic acid present. The air supply of gas appliances required adjustment, but apart from an increased consumption the gas behaved satisfactorily in most of its applications. The pitch from wood and peat was valueless, but the brown tar found a ready market. The wood charcoal proved to be well adapted to use in suction gas producers. Peat charcoal was less satisfactory, as much of it was small and had to be employed as an indifferent domestic and industrial fuel.—H. J. H.

Petroleum industry in Assam; The development of the —. H. S. M. Jack. J. Inst. Petroleum Tech., 1917, 3, 263—276.

AN historical account is given of the progress made up to the present time in opening up and working the oilfields of Assam. The crude petroleum is found in intermittent deposits situated in loose sands. Considerable gas pressures are present. The crude oil has sp. gr. 0.856 and is very dark brown without the fluorescent greenish tint common to many American oils. It is perfectly fluid at 82° F. (27.5° C.), begins to deposit crystals of paraffin at 81° F. (27° C.), and becomes semi-solid at 77° F. (25° C.). The present practice is to subject the crude oil to continuous distillation in boiler stills arranged in groups of three. Crude benzine is taken off from the first still, intermediate kerosene from the second, and the bulk of ordinary kerosene from the third. The residue is distilled to dryness in pot stills, the distillate being passed successively through an anhydrous ammonia refrigerating machine and a carbonic acid machine. From the former is obtained the bulk of wax of high melting point—140° F. (60° C.) normally—and from the latter the basis of the batching oil, used for softening jute fibre. The coke remaining contains 97—98% pure carbon and is used as fuel under the stills. The non-condensable vapours from the boiler stills are used as fuel. The crude benzine is redistilled in closed steam coils, and two qualities of petroleum spirit are produced of sp. gr. 0.710 and 0.750 respectively.—T. St.

Toluene; Determination of — in crude petroleum. S. E. Bowrey. J. Inst. Petroleum Tech., 1917, 3, 287—305.

IN the examination of a crude oil the first operation is the elimination by distillation of all constituents boiling above 150° C., and the removal of unsaturated hydrocarbons from the distilled spirit by washing with sulphuric acid, alkali, and water. 500 c.c. of the prepared sample is then placed in a 1-litre Dewar flask, and washed several times with liquid sulphur dioxide at -35° C., this temperature being obtained by connecting the flask, after the admission of the sulphur dioxide, to a vacuum pump for a short time. After each washing, the sulphur dioxide with dissolved hydrocarbons is drawn over into a separating funnel and the solvent evaporated under reduced pressure. Light paraffins are also volatilised at this stage, together with a small amount of aromatic hydrocarbons. For very accurate determinations of benzene, therefore, it is desirable to use a special form of distilling apparatus for removing sulphur dioxide. Suitable apparatus is described. A 10% solution of sodium hydroxide is next admitted to the separating funnel to absorb sulphur dioxide vapours, drawn off again, and the hydrocarbons run off and measured. This fraction contains substantially all the aromatic hydrocarbons, and consists of about 80% of these substances and 20% of paraffins. A portion is then fractionated very slowly (six drops

per minute), the receivers being changed at 75°, 85°, 105°, 115°, and 130° C. A self-acting device for regulating the speed of distillation is described. This depends for its action on slight changes of pressure within the distillation flask being made to operate a mercury cut-off, acting upon the gas supply. The specific gravity of each fraction is determined by means of a Sprengel tube and the content of benzene, toluene, and xylene, as the case may be, calculated. The specific gravity of the paraffins is deduced from the range of distillation by simply determining the specific gravity of similar fractions from pure paraffin spirit. The aromatic hydrocarbons in intermediate fractions are divided equally between the benzene and toluene, and toluene and xylene, and evaporation loss during distillation is reckoned as made up of $\frac{1}{3}$ benzene and $\frac{2}{3}$ toluene. The total aromatic hydrocarbons left unextracted by sulphur dioxide are determined by nitration, and divided *pro rata* among the benzene, toluene, and xylene as determined in the extracted portion. In an additional note the author states that by adding to the sulphur dioxide extract five times its volume of kerosene (previously washed with sulphur dioxide if necessary), and again extracting with sulphur dioxide, an almost quantitative extraction of pure benzene, toluene, and xylene is obtained. Any paraffins present in the second extract, with the exception of a negligible proportion, boil above 150° C. and are eliminated in the course of fractionation.—T. St.

Gas furnaces; Regenerative —. The E. W. Harvey Gas Furnace Co., Ltd., and E. W. Harvey, London. Eng. Pat. 116,870, Mar. 5, 1918. (Appl. No. 3857 of 1918.)

Is a "uni-directional" regenerative gas furnace having a preheating hearth and a finishing hearth, such as that described in Eng. Pat. 10,824 of 1912 (this J., 1912, 972), the gas is supplied continuously from a horizontal row of orifices at the end of the finishing hearth, and air is supplied from every alternate orifice of a row above the gas orifices. Part of the combustion products is withdrawn through the other alternate orifices, and passes through one of two regenerators. The gas is preheated by passing through the casing close to the regenerators and the hot gas passages. The remainder of the combustion products passes forwards over the preheating hearth. The ports for the air and combustion products may then be reversed. In a modification, the air ports may be divided into two series, above and below the gas ports. An oxidising atmosphere may be produced by placing the gas ports above the air ports or between two series of air ports, and a reducing atmosphere may be produced by placing a series of air ports between two series of gas ports. A low construction of heating chamber may be obtained by arranging the air ports to open through the floor at right angles to the gas ports, or if a clear way is required through the heating chamber, the gas and air ports may be arranged on both sides of the finishing hearth.—W. F. F.

Gas producers, cupola furnaces, and the like; Construction of —. H. A. Bartlett, London. Eng. Pat. 116,185, July 23, 1917. (Appl. No. 10,544 of 1917.)

A LAYER of heat-resisting resilient material is spread on a ferro-concrete base and a firebrick lining built up on it. The outside of the brickwork is covered with a layer of non-conducting resilient material which may be in the form of a rope wound round the brickwork. This material forms the core on which an outer casing of ferro-concrete is built up.—W. F. F.

Vertical retorts for production of illuminating gas. A. Birkholz, Zürich. Ger. Pat. 299,546, Dec. 24, 1915.

THE flue system of vertical retorts is divided into two sections—upper vertical and lower horizontal flues. The producer gas used for heating enters the system at a point about half-way up the retort, meeting the secondary air. The burning mixture travels up the vertical flues to a horizontal collecting channel, whence it is conveyed by a passage down the front of the retort into the top of the lower section of horizontal flues. The gases descend these by a zig-zag course and pass into the recuperators at the bottom. The heating is thereby more intense at the top of the retorts where distillation proceeds more vigorously.

—H. J. H.

Gas producers or other chambers; Apparatus for feeding and distributing fuel or other material to —. F. Thuman, London. Eng. Pat. 116,445, Oct. 25, 1917. (Appl. No. 15,537 of 1917.)

Is an apparatus for feeding fuel into gas producers, gas ovens, cupolas, or retorts without opening the fuel chamber to the air, an air-tight feeding chamber is mounted at the top of the producer or the like, and is provided with a slide-valve for admitting fuel, and a conical valve at the bottom for discharging fuel into the retort. The two valves are operated at the proper intervals by a single rotating cam or by interconnected cams. A rotating guiding spout is provided to deposit the fuel uniformly around the circumference of the retort. A vertical prodding or poking device is caused to act on the material in the feeding chamber during the time the outlet valve is open. In a modification, a stationary circular spreader may be provided below the outlet of the feeding chamber to distribute the material.—W. F. F.

Water-gas containing varying proportions of the component gases; Adaption of twin generator gas plants for the manufacture of —. H. E. Smith, and Perry and Co. (Bow), Ltd., London. Eng. Pat. 116,582, July 12, 1917. (Appl. No. 10,059 of 1917.)

To produce a higher proportion of carbon monoxide in water-gas, two generators are used, through which air is blown in parallel to heat them. A separate chamber lined with fireclay and containing limestone is provided between the two generators and is heated by the combustion products. When steam is passed through the generators in series, the water-gas from the first generator in passing through the limestone liberates carbon dioxide, which is reduced to monoxide in passing through the second generator. The intermediate chamber may be provided with a dividing wall, so that the gas passes through the two compartments in series, and dampers may be provided in this wall to vary the contact with the limestone. To reduce the proportion of carbon monoxide, a secondary jet of steam is passed through the second generator and oxidises part of the carbon monoxide to dioxide. The proportion of carbon monoxide may be reduced in this way to 15%.—W. F. F.

Methane; Process for the synthetic production of — E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 116,302, June 28, 1917. (Appl. No. 3192 of 1917.)

ONE part of coke, charcoal, or graphite in finely divided form is intimately mixed with three parts of one or more of the hydroxides of sodium, potassium, aluminium, manganese, iron, titanium, calcium, barium, or strontium and with about 1 part per 1000 of titanium, uranium, copper, nickel, or their compounds to act as a catalyst. The mixture is placed in a firebrick retort and heated to 400°–1000° C. according to its composition. Methane is liberated and collected.—W. F. F.

Producer; Suction gas — K. Schneidewind, Leipzig. Ger. Pat. 304,091, May 28, 1915.

THE supply of air below the grate is furnished partly through a pipe of fixed aperture and partly through a valve which is automatically controlled by the suction produced by the engine in the delivery pipe of the producer. Above the seat of the valve an inverted cone is suspended from one arm of a balance governor, and from the other a piston working in a cylinder which is connected through two chambers, inserted to damp pulsations, to the delivery pipe. Variations of pressure in the latter raise or lower the cone and thus open or close the valve.—H. J. H.

Gas producer with arrangement for removing coke. Dr. North Kommandit-Ges., Hanover. Ger. Pat. 301,401, Nov. 4, 1916.

THE producer is of section resembling the iron blast furnace, the zone of gasification being the lower portion tapering downwards. The wall of this portion, at about the middle of its height, is pierced by a ring of openings communicating with a closed annular chamber into which coke can fall, and where it cools prior to removal. A slight constriction at the widest place, at the top of the gasification zone, insures regularity of descent of the charge. A portion of the coke can be extracted without interruption and cooling of the producer.—H. J. H.

Washer scrubbers for extracting ammonia, naphtha, and other impurities from coal gas. J. A. Spencer, Southall. Eng. Pat. 116,319, Nov. 24, 1917. (Appl. No. 7674 of 1917.)

THE scrubber consists of a large number of rods or tubes of hard wood or metal assembled in a rotating drum. The ends of the rods are mounted in perforated plates and held in position by outer non-perforated plates secured to the perforated plates by bolts.—W. F. F.

Hydrocarbon oils and the like; Process and apparatus for the cracking of — J. Nelson, Glasgow. Eng. Pat. 116,304, Mar. 13, 1917. (Appl. No. 3668 of 1917.)

HYDROCARBON oil or vapour is forced through a bath of liquid material, such as molten metal, maintained at a suitable temperature. For working at moderate temperatures, molten lead is a suitable contact substance; for higher temperatures, metals or alloys of higher melting point may be used. The extent of cracking may be controlled by varying the depth at which the oil or vapour is delivered below the level of the liquid, and the whole or a part of the product, e.g., the heavier fraction, may be again treated in a similar manner. If the hydrocarbon contains tarry matter, or other substances which cannot be volatilised, it may be distilled from an auxiliary vessel, and the distillate or vapours then subjected to the cracking

process. The passage of the vapours through the liquid keeps it thoroughly agitated, thus maintaining a uniform temperature throughout the contact mass and preventing accumulation of carbonaceous material. A simple form of apparatus for the process consists of a vertical cast-iron cylinder about 2 ft. 6 in. high and 2½ in. internal diameter, heated at its lower end, and provided at the upper end with a lateral exit pipe and a gas-tight cover through which passes an adjustable inlet pipe, the lower end of which is immersed in a quantity of molten lead. Kerosene of sp. gr. 0.803 after one treatment in this apparatus, the lead being maintained at about 700° C., and the inlet pipe dipping 4 in. below the surface of the lead, yields about 20% of light spirit of sp. gr. 0.757 and boiling at or below 160° C., no carbonaceous deposits being formed. Other forms of apparatus are described in which the vapours are caused to pass several times through a bath of the molten metal, e.g., by means of vertical internal partitions, open alternately above and below the liquid, the apparatus being essentially free from constrictions or long highly-heated channels.—L. A. C.

Mineral oils; Apparatus for refining — C. E. Lapp, Los Angeles, Cal. U.S. Pat. 1,266,281, May 14, 1918. Date of appl., Nov. 5, 1917.

A HELICAL pipe coil is mounted vertically within a cylindrical wall mounted on a base. The convolutions of the coil are held spaced apart by supporting columns which are made up of units fitted together end to end, and have seats in their ends to receive the convolutions of the coils. Draw-off pipes leading upwards from various parts of the coil are provided, and means for securing the units together.—T. St.

Montan wax; Extraction of — from lignite. A. Riebeck'sche Montanwerke Akt.-Ges., Halle. Ger. Pat. 305,349, Aug. 9, 1916.

LIGNITE is dried until its moisture content does not exceed 25% and then extracted with a mixture of alcohol and benzene.—L. A. C.

Naphthenic acids; Process for treating [deodorising] — Erdöl-Verwertungs-Akt.-Ges., Berlin. Ger. Pat. 305,771, Sept. 17, 1916.

NAPHTHENIC acids, either alone or mixed with fatty acids, are treated with nitrous acid, halogens, or hypohalogenous acids, preferably by blowing a stream of air charged with the reagent through the oil, or else by the action of substances which liberate such reagents, with or without the addition of acids, the reagents being used in small quantities just sufficient to overcome the odour of the naphthenic acids.—J. F. B.

Coke discharged from retorts or furnaces; Apparatus for removing — Drakes, Ltd., and J. W. Drake, Halifax. Eng. Pat. 116,567, June 27, 1917. (Appl. No. 9188 of 1917.)

Retorts; Vertical — for distilling, carbonising, roasting and the like of coal, carbonaceous, and other material. H. R. L. Walker and W. R. Bates, London. Eng. Pat. 116,458, Nov. 17, 1917. (Appl. No. 16,951 of 1917.)

In a vertical retort for the destructive distillation of coal, shale, peat, or wood, gas burners are placed in inclined radial passages in the walls, and secondary air is drawn in through segmental, vertical passages in the walls. The combustion products pass upwards through zig-zag flues surrounding the central carbonising chamber, and then downwards through segmental flues alternating with the secondary air passages, to a transverse horizontal flue passing through the retort. The gases then pass upwards through a central concentric heating flue to the discharge flue. The volatile distillation products are withdrawn from the top of the annular retort. The charge is fed from a hopper and is moved downwards by an annular ram operated hydraulically. To facilitate removal of the coke, the upper side of the transverse flue is constructed as a knife edge.—W. F. F.

Leading-in conductor [e.g., for electric lamps]. R. Jacoby, Berlin, Assignor to General Electric Co. U.S. Pat. 1,265,665, May 7, 1918. Date of appl., Apr. 8, 1914.

III.—TAR AND TAR PRODUCTS.

Naphthalene; Determination of — in tars and tar oils. Knublauch. J. Gasbeleucht., 1918, 61, 134—137, 145—149.

THE author's method of estimating naphthalene by direct titration of the picrate with standard alkali (this J., 1917, 702) has been adapted to the analysis of tars and tar oils. The precipitation is effected with both the sample and the picric acid in alcoholic solution. After mixing, the solution is diluted with water, and the precipitation is complete if the resulting solution contains not more than 10% of alcohol and at least 0.2% of picric acid or less than 12.5% of alcohol and at

least 0.3% of picric acid. The quantity of picric acid must be chosen to ensure these end concentrations without the precipitation of free picric acid. *Crude naphthalene and tar oils.* A quantity containing 0.1—0.2 gm. of naphthalene is weighed into a 200 c.c. conical flask; 15 c.c. of absolute alcohol is added and picric acid equal to 2 to 2½ times the weight of naphthalene. The flask and contents are heated to 60°—65° C. until all is dissolved, cooled, and the volume made up to 120 c.c. with a 0.3% aqueous solution of picric acid. After 1 hour the precipitate is collected on a 10 cm. smooth filter and washed with a 0.2% picric acid solution. The paper and contents are transferred to a small beaker with 50—80 c.c. of water and titrated with N/10 caustic soda, using methyl orange as indicator, a deduction of 0.2 c.c. being made for the picric acid retained by the paper and precipitate. Phenol does not interfere. The results with pure naphthalene were quantitative. *Tar.* The quantity taken should contain about 0.07 gm. of naphthalene, the proportion of picric acid as above but in no case more than 0.6 gm. so as to avoid precipitation at the end. In the case of viscous tars, the sample is weighed into a small beaker and the picric acid dissolved in 15 c.c. of alcohol added. After heating the beaker and contents to 60°—65° C., the tar is carefully extracted by stirring and manipulation with a glass rod for at least 30 minutes. When cold, 15 c.c. of water and 120 c.c. of 0.3% aqueous picric acid solution are added. Leaving the tar residue in the beaker, the picrate precipitate is transferred to a filter and the determination continued as above. Tars containing much light oil and little naphthalene give unsatisfactory end points, and in such cases the picrate precipitate is decomposed by an excess of N/10 caustic soda, the liquid is washed with hot water into a small beaker, and then filtered into a conical flask. 5—6 c.c. of a neutral solution of an ammonium salt is added and the ammonia liberated is determined by distillation into a measured volume of N/10 sulphuric acid. When the filtration of the picrate is difficult, the tar is extracted with 15 c.c. of a solution of picric acid in alcohol, the extract being poured into a conical flask. Further extractions are made with 35 c.c. of alcohol, and the washings added to the first, leaving the tarry residue behind. 35 c.c. of the alcohol is removed by distillation and the determination of the picrate continued as described. *Light oils or tar oils.* It is necessary to remove a portion of the light oil before precipitation. The oil taken is treated with the picric acid dissolved in 25 c.c. of alcohol and a portion of this is distilled off. After cooling, the 0.3% solution of picric acid is added so as to dilute the alcohol ten times and the determination is completed by one of the methods described. The volume of alcohol distilled and the weight of picric acid taken must be chosen so that the end concentrations are appropriate.—H. J. H.

Pitch, asphaltum and similar substances; Method for measuring the coefficient of expansion of —. K. Kawakami. Kōgyō-Kwakaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 24, 107—112.

THE apparatus consists of a glass cylinder, 2 cm. in diam. and 11.5 cm. long, provided with a glass stopper carrying a graduated capillary tube about 13 cm. long. The substance to be tested is melted and poured into the cylinder, leaving a small space about 1 cm. deep on the top, and allowed to cool. The space above the substance is next filled with coloured water and the stopper is placed in the cylinder. The level of the water in the capillary is adjusted to zero and the whole apparatus is placed in a water thermostat kept at the required temperature until the rise of the water in the

capillary ceases. The capillary is calibrated by filling with mercury, and the volumes of the whole apparatus and of the water are also measured. From the above data the volume expansion of the substance is calculated, correction being made for the expansion of the water and of the glass.

—J. F. B.

p-Aminophenol; *Electrolytic preparation of* —. T. Shōji. *Kōgyō-Kwagaku-Zasshi* (J. Chem. Ind., Tokyo), 1918, 21, 117—136.

THE author has studied the conditions for the preparation of *p*-aminophenol by the electrolytic reduction of nitrobenzene in presence of sulphuric acid. Platinum electrodes are most satisfactory, but a carbon cathode may be used. The concentration of the sulphuric acid must not exceed 80%. In order to avoid sulphonation of the aminophenol. The quantity of sulphuric acid should be five times that of the nitrobenzene. The temperature must be kept at about 80° C., as a higher temperature accelerates sulphonation. The current density should be 8—9 amp. per sq. dm. and the E.M.F. 6—8 volts. Vigorous agitation of the electrolyte is most important from the point of view of efficiency, and with good agitation the quantity of electricity consumed is nearly theoretical. The cathode chamber must be kept closed to avoid loss of nitrobenzene by evaporation. Under these conditions the yield of *p*-aminophenol is 43% of the theoretical. A portion of the sulphuric acid may be used again after making up with strong acid; another portion may be used for neutralisations, *e.g.*, of alkali fusions, etc. In spite of the low yield the method is capable of competing with the chemical method on account of its simplicity and because nitrobenzene is a cheaper raw material than phenol.—J. F. B.

Anthraquinone; Determination of —. H. F. Lewis. *J. Ind. Eng. Chem.*, 1918, 10, 425—426.

A METHOD for the separation of anthraquinone from anthracene and phenanthraquinone consists in boiling the mixture with an excess of 5% sodium hydroxide solution and zinc dust; the anthraquinone is reduced to oxanthranol (Graebe and Liebermann, *Annalen*, 1871, 160, 126) and goes into solution. The mixture is filtered and the insoluble portion treated with further quantities of alkali and zinc dust. When the filtrate is shaken with air, the anthraquinone is re-oxidised, and may be collected, dried, and weighed. (See also *J. Chem. Soc.*, Sep., 1918.)—W. P. S.

Organic sulphur compound; Preparation of a new type of —. G. N. White. *Chem. Soc. Trans.*, 1918, 113, 608—609.

THE crystalline sodium salt of β -naphthylthiosulphoxylic acid, $C_{10}H_7S_2O_2Na$, can be obtained by heating a mixture of β -naphthyl disulphide, sulphur, and sodium sulphide crystals. The corresponding lead salt, obtained by double decomposition, gradually decomposes when kept, changing from its original deep orange colour through scarlet and brown to black, whilst when heated with alcohol it yields β -naphthyl disulphide. It is probable that analogous compounds are formed as intermediate products in the manufacture of sulphide dyes.

IV.—COLOURING MATTERS AND DYES.

Naphthol- and naphthylamine-sulphonic acids; Action of tetrazodi-o-tolylmethane chloride on —. I. J. H. Stebbins, jun. *J. Ind. Eng. Chem.*, 1918, 10, 445—448.

TWO red dyes are obtained by the action of tetrazodi-o-tolylmethane chloride on 1,4-naphtholsulphonic acid; one, which is formed in aqueous solution, contains one mol. of 1,4-naphtholsulphonic acid and is insoluble in water, the other, containing two mols. of the acid, is produced when the reacting solution contains alcohol; it is soluble in water. These two products dye wool but have no affinity for cotton. In aqueous sodium carbonate solution tetrazodi-o-tolylmethane chloride combines directly with two mols. of 2,3,6-naphtholdisulphonic acid. (See also *J. Chem. Soc.*, 1918, I., 353.)—W. P. S.

PATENTS.

Acid wool dyestuffs; Manufacture of — indifferent to copper. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 116,530, June 11, 1917. (Appl. No. 8329 of 1917.) Addition to Eng. Pat. 15,127, Oct. 26, 1915.

DYESTUFFS containing copper and soluble in water are prepared by treating mordant-dyeing azo-

dyestuffs derived from diazocarboxylic acids of the benzene or naphthalene series or from nitro-, sulpho-, or halogen derivatives of such acids, which contain no hydroxyl group in o-position to the diazo-group, with copper or a copper compound, as described in Eng. Pat. 1611 of 1915 (this J., 1916, 301), or by producing the dyestuffs in presence of copper or a copper compound as described in Eng. Pat. 15,127 of 1915 (this J., 1916, 1104; see also Eng. Pats. 12,249, 13,204, and 16,916 of 1915; this J., 1916, 419, 922, and 1917, 78).—L. A. C.

Azo-dyestuffs; Manufacture of chromium compounds of —. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 116,535, June 12, 1917. (Appl. No. 8420 of 1917.) Addition to Eng. Pat. 104,045, Mar. 13, 1916.

ACCORDING to the present process, which is a modification of that described in the chief patent (see U.S. Pat. 1,221,849; this J., 1917, 542), chromium compounds of azo-dyestuffs, used for producing fast tints in an acid bath, as described in Eng. Pat. 15,456 of 1915 (this J., 1916, 1255), may be prepared by treating the dyestuff in presence of a solvent (e.g., water) at a raised temperature with chromium hydroxide or a hydrated chromium oxide, preferably in freshly precipitated or colloidal condition, or with a normal chromate, with or without the addition of a reducing agent or an alkali-fixing agent, or both.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER

Textile fibres; Investigations on —. W. Harrison. Proc. Roy. Soc., 1918, A, 94, 460—469.

DOUBLE refraction in textile fibres is due to the presence of internal stresses. It may be increased by compressing the fibres, for instance, between a thick glass plate and a grooved celluloid film placed on a second glass plate, the whole being examined on the stage of a microscope in polarised light between crossed nicols and the difference between the compressed and uncompressed portions noted. Examined in this way under a pressure of 5 tons per sq. in., wool fibres showed interference figures indicating spreading of the fibre substance in all directions away from the centre of pressure; cotton fibres offer greater resistance to deformation than wool fibres and show no interference figures. After removal of the pressure, in both cases, the fibres did not return to their original shape; the increased double refraction of the compressed portions remains until the stresses are relieved by immersion in water. The return to the original shape in cold water is much more rapid in the case of wool than in that of cotton. Similar results were obtained when fibres which had been bent

or twisted were placed in cold water. Fibres subjected to a limited amount of extension when dry do not return to their original length when kept loose in a dry atmosphere, but do so rapidly when placed in water; the effect of a humid atmosphere is the same as that of cold water but much less rapid. At high temperatures, water renders fibres truly plastic; deformation is produced by compression, but this causes little or no internal stresses. These experiments have a bearing on the "feel" and finish of textile fabrics. The double refraction shown by cotton fibres in the natural state is due to permanent strain produced by internal stresses; it disappears when the fibre is swollen by cuprammonium solution, except in those bands where swelling has not occurred. The direction of strain is parallel to the axis of the fibre and the natural condition of cotton fibres corresponds with that produced by tension on an elastic body; all the other natural fibres appear to be subject to similar stresses. The shrinkage in length which takes place on mercerisation appears to be due to the balancing of the internal stresses. The condition of a highly nitrated cotton fibre containing more than 12.5% of nitrogen is just the reverse and corresponds to that produced in an elastic body by compression in the direction of the axis. In both cotton and wool the distribution of the internal stresses is irregular. The modification of the internal stress produced by boiling wool in water is similar to that produced by treating cotton fibres with concentrated alkalis. Cold water has no influence in relieving the natural internal stresses, probably because these are due to changes in volume, whereas stresses caused by external compression are only due to changes in shape. Artificial fibres are generally produced with internal stresses which cause double refraction, similar to those occurring in natural cotton, and the physical forces which are operative in the formation of artificial fibres from viscous fluids are analogous to those acting in the formation of natural fibres from plastic cell materials.—J. F. B.

Cotton plant; Chemistry and histology of the glands of the — with notes on the occurrence of similar glands in related plants. E. E. Stanford and A. Viehoever. J. Agric. Research, 1918, 13, 419—435.

INTERNAL glands occur in the cortex, foliage, flower and seed of the different species of cotton plants, and to some extent in plants of allied genera (*Thespesia*, *Eriogonon*, etc.). The glands in portions of the plant exposed to light contain quercetin, probably in the form of its glucosides, quercimeritrin or isoquercitrin, ethereal oil, resins, and possibly tannins. They are surrounded by flattened cells which contain a red anthocyan pigment. The glands not normally exposed to light contain gossypol and are surrounded by a layer of flattened cells which do not contain anthocyanins. On exposure to the light the gossypol is replaced by quercimeritrin. —C. A. M.

Hemp; Korean —. K. Ueda. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 314—319.

HEMP bast fibre is produced in large quantities in Korea; it is prepared by an artificial retting process and the scutching is done by hand. The strands average 1.2—1.3 m. in length and 0.6—0.7 mm. in breadth; the fibre has a pale yellow colour and appears of excellent quality. An analysis of a typical specimen showed: moisture, 9.77; ash, 2.07; oil and wax, 1.26; aqueous extract, 7.30; cellulose, 71.03; incrusting matter, 10.64%. The cellulose was determined by Cross and Bevan's method; lignocellulose was present in the raw fibre.—J. F. B.

Chemistry of the cotton plant, with special reference to Upland cotton. Viehoever and others. See XX.

PATENTS.

Cotton; Process for imparting a transparent appearance to —. E. Heberlein, Wattwil, Switzerland. U.S. Pat. 1,265,082, May 7, 1918. Date of appl., July 20, 1917.

TRANSPARENT effects on cotton fabrics are produced by subjecting the goods to the action of a caustic alkali solution of at least 15° B. (sp. gr. 1.109), washing and then treating with sulphuric acid of at least 50.5° B. (sp. gr. 1.498), both treatments being carried out at a temperature below 0° C. The order of the treatments may be reversed, and the two treatments may be repeated alternately; one of the reagents may be caused to react only in places to produce pattern effects, and the fabrics may be treated under tension.—J. F. B.

Cellulose; Manufacture of coverings or masses of structureless —. C. F. Cross, London, and Visco Development Co., Ltd., Bromley, Kent. Eng. Pat. 116,366, June 12, 1917. (Appl. No. 8418 of 1917.)

CELLULOSE regenerated from viscose is deposited in the form of a covering or mass and washed; the shrinkage which takes place during drying is regulated by subjecting the covering or mass during the period of dehydration to an intermittent or continuous rolling pressure, which is increased as the dehydration proceeds. For instance, annular cylinders of structureless cellulose are prepared by regenerating cellulose from viscose in a cylindrical mould with a core; the core is removed, and the cellulose cylinder washed free from salts; the cellulose is mounted on the spindle or other article to be covered and allowed to shrink thereon, it is then rolled on or by a rigid surface under pressure during the drying process, which may be assisted by heat or hot air. At a certain stage, preferably when the mass contains about 60% of cellulose and 40% of water, glycerin may be applied to the cellulose and worked in by the rolling.

—J. F. B.

Hanks or warps of yarn, woven or felted fabrics, leather, and fibrous materials; Machinery employed for drying —. T. Ogle, Leeds. Eng. Pat. 116,214, Oct. 22, 1917. (Appl. No. 15,281 of 1917.)

THE material, suspended from carriers travelling on chains, passes through a central longitudinal chamber separated by partitions from two lateral compartments. Fans and heating arrangements are situated in the lateral compartments and slots are pierced in the partitions through which heated air passes into the central chamber, the slots being arranged in groups alternately so that those which are at the top on one side are directly opposite to slots at the bottom on the other side. The air is thus caused to circulate across the chamber diagonally and through the material from one side to the other alternately and in an upward or downward direction, or both.—J. F. B.

Acetyl cellulose, and process of making same. W. G. Lindsay, Newark, N.J., Assignor to The Celluloid Co. U.S. Pat. 1,265,216, May 7, 1918. Date of appl., July 11, 1914.

CELLULOSE is treated in a preliminary bath with alcohol and acetic acid or other diluent, which without itself altering the cellulose induces acetylation in the subsequent process; the treated cellulose is then treated with a mixture of acetic anhydride

and a diluent, such as benzene. The product consists of fibrous acetylcellulose which has its original structure unaltered and is soluble in acetylene tetrachloride.—J. F. B.

Acetylcellulose; Compound of — and process. W. G. Lindsay, Newark, N.J., Assignor to The Celluloid Co. U.S. Pat. 1,265,217, May 7, 1918. Date of appl., Sept. 1, 1916.

AN acetylcellulose, which becomes plastic in chloroform, is dissolved together with camphor in a common solvent, a liquid monohydroxyaliphatic alcohol having more than two carbon atoms is added, and the mixture dried.—J. F. B.

Pyroxylin composition. F. Sparre, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,266,073, May 14, 1918. Date of appl., Sept. 3, 1914. Renewed Sept. 28, 1917.

A PYROXYLIN which is soluble to the extent of at least 50% in a mixture of equal parts of commercial ethyl alcohol and benzene is dissolved in a solvent containing 45–60% of benzene, 30–45% of alcohol, and 3–15% of a more powerful solvent, such as amyl acetate.—J. F. B.

Lignonesulphonic acid or its salts; Method of preparing nitroso compounds from —. E. Oman, Stockholm, Sweden. Eng. Pat. 103,651, Jan. 4, 1917. (Appl. No. 205 of 1917.) Under Int. Conv., Jan. 20, 1916.

LIGNONESULPHONIC acid or one of its salts is treated with nitrous anhydride or substances yielding nitrous anhydride. For example, sulphite-cellulose waste lye, after precipitation of the ligninsulphonates by salt and concentration to about one-sixth of its volume, is treated with a solution of about 60 grms. of sodium nitrite per litre of concentrated filtrate and 300–500 grms. of 20–25% sulphuric acid whilst cooling and stirring, and the nitroso compound is precipitated by adding a salt, e.g., sodium sulphate. (Reference is directed in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Act, 1907, to Eng. Pat. 103,653; this J., 1918, 146A.)

—J. F. B.

Sulphite cellulose waste lye; Method of treating — to make it suitable for further treatment. E. Oman, Stockholm, Sweden. Eng. Pat. 106,493, May 12, 1917. (Appl. No. 6793 of 1917.) Under Int. Conv., May 13, 1916.

SULPHITE waste lye at a concentration of 10% dry substance contains about 25% of sugars, 25% of calcium ligninsulphonates, and 5% of calcium lignonesulphonates. The ligninsulphonates are precipitated by saturating the waste lye, without any preliminary treatment, with sodium chloride and heating to 50°–70° C., and the lignonesulphonates remain dissolved in the saturated liquid, even after concentration (see also this J., 1918, 121A). (Reference is directed under Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 20,036 of 1893; this J., 1894, 1085.)—J. F. B.

Paper, textilose, or other similar material; Manufacture of thread, string, and cord from strips of —. Soc. Alsacienne de Constructions Mécaniques, Belfort, France. Eng. Pat. 113,970, Mar. 6, 1918. (Appl. No. 3914 of 1918.) Under Int. Conv., Apr. 27, 1914.

Wood; Machine for comminuting — [for making wood pulp]. A. G. Bloxam, London. From Zellstoff-fabrik Waldhof, Mannheim-Waldhof, Germany. Eng. Pat. 116,604, Aug. 10, 1917. (Appl. No. 11,536 of 1917.)

Paper; Apparatus for regenerating old —. B. A. Navarre, Lyon, France. U.S. Pat. 1,265,809, May 14, 1918. Date of appl., Sept. 14, 1917.

SEE Eng. Pat. 114,257 of 1917; this J., 1918, 264 A.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Acer ginnala; Application of leaves of — [for dyeing, etc.] in Korea. Y. Ueda. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 211—219.

A SPECIES of maple tree, *Acer ginnala* (Korean name "Shinnamm"), is widely distributed in Korea. The leaves contain about 16% of tannin and a small quantity of yellow colouring matter. The extract is prepared by boiling the leaves with water and evaporating; the yield is about 30%. Analyses of Shinnamm extract showed: moisture, 16.29 and 19.50%; tannins, 38.47 and 37.71%. Used as a dyestuff it gives, on cotton, black and grey shades with iron mordant and khaki with chrome-copper mordant; on silk and tussah, black suitable for weighting purposes with iron mordant; on wool, fast khaki with chrome mordant.—J. F. B.

Aniline Black; Notes on steamed —. E. Bechtel. Färber-Zeit., 1917, 28, 300. Z. angew. Chem., 1918, 31, Ref., 182.

IN place of hydrochloric acid a mixture of hydrochloric and nitric acids may be used with advantage. The vegetable fibre is not injured and the liberated chlorine contributes to the oxidation of the aniline. Potassium ferrocyanide may be replaced by the sodium salt in presence of which the black is oxidised more rapidly. The calcium salt is not so satisfactory, as it tends to form sparingly soluble double salts with potassium and sodium salts. The ferrocyanides also exert a neutralising influence. The mineral acid decomposes principally the chlorates, with the formation of oxygen, chlorine, and chlorous acid, and this mixture of oxidising gases becomes active during the steaming of the goods to develop the colour. A mixture of ferrocyanide with aniline oil and acid does not produce a black but gives a blue on vegetable fibres; this imparts a certain freshness to a black which is not excessively soaped and neutralises in a physical sense the action of the reducing agents which cause "greening." In the strongly oxidising atmosphere which is necessary for the development of Aniline Black, the discharge of *p*-Nitraniline Red by hydrosulphite-formaldehyde is very easily effected. A temperature of 90° C. and a short treatment of one minute is amply sufficient, whereas in the ordinary way in an atmosphere free from air a temperature above 100° C., and a treatment of several minutes are employed.

—J. F. B.

Vat dyestuffs; Process for printing coloured reserves with certain —. R. Haller. Färber-Zeit., 1917, 28, 247—249. Z. angew. Chem., 1918, 31, Ref., 183. Sealed communication, Soc. Ind. Mulhouse, Jan. 21, 1913.

IT is well known that zinc or manganese salts or a mixture of the two act as an efficient reserve in Indanthrene dye-baths, and there are various methods for thus obtaining white effects. If a vat dyestuff be added to such a reserve, e.g. Indanthrene Yellow, together with stannous oxide and anthraquinone, it is possible by simple dipping of the printed goods in an Indanthrene or other similar dye-bath, to fix the added colour in pure shade. The alkali of the Indanthrene dye-bath penetrates into the reserve and, in conjunction with the stannous oxide, reduces the vat dyestuff present in it, while the manganese and zinc salts also present in the reserve prevent it from taking up the colour from the main dye-bath. Still better results are obtained if "Hydrosulphite conc." and a solution of potassium sulphite are added to the printing colour. By this means the added dyestuff is already reduced in the printing colour, so that the leuco-compound is dissolved by the alkali of the dye-vat and converted into a form in which it is most easily fixed on the fibre. The addition of a little stannous chloride assists the reduction process. It has also been found that Rongalite and ferrous sulphate mixed with the printing colour and added to the dyestuff will also produce coloured reserves in Indanthrene dye-vats. The printed goods are steamed at 105°—110° C., passed through the dye-bath, scoured, washed, and dried. The alkali dissolves the leuco-compound and enables it to be fixed on the fibre. The ferrous sulphate acts in the first place as a reserve but also completes the reduction of the printed dyestuff.

—J. F. B.

Vat dyestuffs; Explanation of Haller's process for printing coloured reserves on certain —. H. Pomeranz. Färber-Zeit., 1917, 28, 309—310. Z. angew. Chem., 1918, 31, Ref., 183.

IN Haller's process (see preceding abstract) it remains unexplained how the neutralisation of the alkali and its action as a fixing agent can proceed simultaneously. Haller uses for his printed reserve an addition of anthraquinone and zinc chloride. The special case of Indanthrene Yellow printed as a reserve in an Indanthrene Blue vat is explained by the fact that the anthraquinone and the zinc hydroxide precipitated by the alkali from the zinc chloride present a certain resistance to the fixation of the Indanthrene Blue but not to that of the Indanthrene Yellow. This difference in behaviour of the two dyestuffs would be sufficient to account for the fixation of the yellow in preference to the blue, in view of the short time of immersion in the blue dye-vat. A similar explanation holds for the second reserve method described by Haller, only in this case there is the additional influence of the ammonium base in the Rongalite CL, which is also opposed to the fixation of the Indanthrene Blue.—J. F. B.

Investigations on textile fibres. Harrison. See V.

PATENTS.

Wool, yarn or other fibrous material; Apparatus for scouring, dyeing, or otherwise treating with liquor —. H. Walker, Cleckheaton. Eng. Pat. 116,129. (Appl. Nos. 7603, May 26, and 17,253, Nov. 23, 1917.)

THE liquor is contained in a trough in which are situated a number of perforated cylinders with or without vanes inside them. A travelling apron carries the material under the perforated cylinders

and between groups of rollers situated between each two cylinders throughout the length of the machine. The material may be held in position on the apron by one or more guiding tapes or bands which travel with the apron and return outside the trough above the cylinders. The action of the perforated cylinders on the travelling material causes the liquid to circulate in and out of the material in a vertical direction without disturbing its arrangement.—J. F. B.

Azo colours; Production of insoluble — on the fibre. The Imperial Trust for the Encouragement of Scientific and Industrial Research, London, and G. G. Hepburn, Manchester, Eng. Pat. 116,360, June 11, 1917. (Appl. No. 8303 of 1917.)

THE material is printed or impregnated with a solution obtained from a "diaz salt" or "tetrazo salt" prepared by mixing diazonium salts with salts of 2-naphthol-1-sulphonic acid (Eng. Pat. 11,757 of 1895; this J., 1896, 446), and dissolving the compound so obtained in a solution of caustic soda, in the proportion of one molecule of the latter for each diazo group, or in a solution of a salt having an alkaline reaction, and then developing the colour by ageing or steaming or by an acid bath or atmosphere. In printing, the solution may be printed on the material previously impregnated with an acid or acid salt. A solution for producing *p*-Nitraniline Red is prepared by treating the diazo salt from *p*-nitraniline and 2-naphthol-1-sulphonic acid with an alkali or alkaline salt.—J. F. B.

[Aniline] Black; Production of — on vegetable fibres. The Calico Printers' Association, Ltd., and E. A. Fourneaux, Manchester, Eng. Pat. 116,562, June 23, 1917. (Appl. No. 9022 of 1917.)

THE ingredients specified in Eng. Pat. 115,278 of 1917 (this J., 1918, 367 A) are employed, with the addition of boric acid, by itself or in conjunction with a phosphoric acid, preferably metaphosphoric acid, which gives a relatively soluble aniline salt. The proportion of boric acid may vary between 0.5 and 1 mol. per mol. of aniline, but when bases of the benzidine series are present it may be considerably less. The use of boric acid, with or without phosphoric acid, obviates the loss of aniline which tends to occur when the goods are dried without due care. Example: aniline, 60; aniline salt, 20; *p*-phenylenediamine dihydrochloride, 3; formic acid (90%), 90; lactic acid (30%), 48; metaphosphoric acid, 12.75; boric acid, 20; sodium chloride, 48; copper chloride, 11 parts by weight, made up with water to 1000 by volume with the required amount of thickening.—J. F. B.

Slubbing yarn and the like; Dyeing of — and apparatus therefor. P. Crayton, Bradford, Eng. Pat. 116,652, Dec. 7, 1917. (Appl. No. 18,123 of 1917.)

THE tops are unwound and the slubbing is passed into an upright dyeing box perforated at the top and bottom and divided by means of perforated loose shelves into a series of superposed chambers, so as to permit the dye liquor to circulate freely in an upward or downward direction through the material, each chamber containing an equal proportion of the slubbing, and the slubbing in the successive chambers being passed through a central opening in each shelf and maintained in one continuous unbroken length suitable for rewinding from the box. The dye box also has upright slots in the sides which can be closed when necessary, and dye liquor may be circulated either in a vertical direction or in a lateral direction without disturbing the arrangement of the slubbing.

—J. F. B.

Beam dyeing machine. E. and L. Holt, Burlington, N.C. U.S. Pat. 1,265,332, May 7, 1918. Date of appl., July 13, 1914.

THE yarn treating apparatus comprises a closed receptacle, a mixing tank surrounding the receptacle in the form of a jacket, and a circulating system for circulating liquid from the mixing tank in different directions through the receptacle. The receptacle may be constructed in the form of a vat having ports, and fluid is introduced from the circulating system through either port and is withdrawn through the other port; a perforated yarn-holding member is enclosed within the vat having an open end above one of the ports, guides are fixed converging towards the last-mentioned port to be engaged by the yarn-holding member and to guide it into position, and means are provided for holding it in position.—J. F. B.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,266,108 and (B) 1,266,109, May 14, 1918. Dates of appl., (A) Apr. 6, (B) May 16, 1917. (See also this J., 1918, 412 A.)

(A) A HORIZONTAL dyeing receptacle has pyramidal flanges at both ends and a series of parallel foraminous plates within the dyeing receptacle; means are provided for maintaining the plates at predetermined distances from each other, and a chamber is situated at each end of the receptacle having flanges which abut against those of the receptacle, making a tight joint; means are provided for passing liquid and air through the chambers and foraminous plates, also for removing the liquid from the dyeing chamber after it has passed through a chamber and some of the plates, means for revolving the dyeing receptacle and for removing the receptacle from abutment with the chambers. A smaller and similar testing device is provided externally so that the material may be examined without interrupting the main treatment. (B) In a vertical type of apparatus the receptacle contains a series of fibre chambers with non-perforated sides and foraminous plates, top and bottom, adjustable relatively to each other, a second series of fibre chambers, a liquid chamber below the series of fibre chambers, a second liquid chamber containing a series of nested members diverging upwards, a pump which forces the liquid upwards between the nested members, and through the liquid chambers and fibre chambers to a reservoir, from which it returns to the pump. The foraminous plates are composed of a series of concentric rings with connecting members, the top plate having elements extending downwards and the bottom having elements extending upwards.

—J. F. B.

Fabric-treating device. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,266,110, May 14, 1918. Date of appl., June 20, 1917. (See also this J., 1918, 412 A.)

THE receptacle contains a foraminous cylinder comprising a series of spaced parallel members having projections extending outwards within the receptacle, an inner foraminous cylinder spaced from the outer cylinder, tubes connecting the openings in the inner cylinder with a supply source of liquid, steam, and air, sliding annular members capable of closing all the openings on the outer cylinder which are not covered by fabric and arranged to abut on the edges of the fabric wound on the cylinder, a flexible foraminous cover tightly adjustable around the outside of the fabric, and means for rotating the cylinders and for forcing liquid, steam, and air through the goods. A testing device which revolves with the cylinders is connected with the space between the two foraminous cylinders.—J. F. B.

Sericin soap for dyeing silk and yarns and fabrics of silk or silk waste; Manufacture of a substitute for —. Gebr. Schmid, Basle, Switzerland. Ger. Pat. 305,239, Sept. 12, 1917. Addition to Ger. Pat. 291,075 (see Eng. Pat. 100,169 of 1916; this J., 1916, 734).

A SMALL quantity of acid is added to the water used in the original process, to facilitate the dissolving of the chrysalides by acting on their oil and to prepare them for the further treatment.

—J. F. B.

Silk; Process for dyeing black and weighting —. F. C. Schmidt, Wolgast. Ger. Pats. (A) 305,275, (B) 305,770, Mar. 9, 1913, and Feb. 19, 1916.

(A) IN the usual process of dyeing Logwood Black on silk and weighting the goods, the number of tin phosphate baths is reduced and sodium or potassium silicate is substituted for the Marseilles soap in the first logwood bath. In order to avoid the usual topping with an aniline dyestuff, a suitable iron bath is given after the first logwood bath and dyeing is completed in the second dye bath without an aniline dyestuff. Treatment with tannin is omitted and the shade thereby becomes richer and the silk retains more lustre; a loading of 75–80% is attained with the same number of tin phosphate treatments as give only 20–25% when tannin and iron are employed. By this process the haematoxylin is oxidised in the fibre to haematein and is absorbed in much greater quantities than when tannin has been used. In dyeing without iron the aniline dyestuff may be added to the logwood bath, whereas the tannin-iron black hinders the absorption of aniline dyestuffs. (B) Sodium silicate is used in the logwood bath instead of soap and one or several dyeing treatments may be given. The substitution of silicate for soap gives a higher loading and a more bulky fibre.—J. F. B.

Paper; Process of printing —. C. Jäger G.m.b.H., and R. W. Carl, Düsseldorf, Germany. Eng. Pat. 116,109, Dec. 27, 1916. (Appl. No. 18,508 of 1916.)

DYES soluble in water or insoluble lakes or pigments are mixed with gelatin compounds such as glue, agar-agar, sugar materials, or casein and with a substance capable of forming formaldehyde at a temperature such as is attained by the rollers of the printing machine (up to 80° C.), e.g. hexamethylenetetramine. If a dyestuff be employed which itself gives insoluble compounds with formaldehyde, e.g. the direct cotton dyestuffs, the nitrogenous colloid may be wholly or partially omitted or replaced by substances which do not react with formaldehyde. Example: 100 parts of lampblack is mixed with 400 of water, 1500 of glue dissolved in 1500 of water is added and then 500 of hexamethylenetetramine. Paper printed with these inks can be bleached and used again.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Intensive system of manufacturing —. J. Thede. Z. angew. Chem., 1918, 31, 2–3, 7–8.

THE intensive system of manufacturing sulphuric acid, which is characterised by an increased circulation of the nitrogen compounds through the

chambers, requires special arrangements to obtain full working efficiency. Petersen's chamber regulator (this J., 1910, 1250) has given good results in practice, whilst Meyer's process, in which the gases are introduced tangentially into cylindrical chambers, promotes the formation of the acid. The primary requisite, however, is great height of the lead chambers, which should not be less than 10 to 15 m. high. As an example of how a considerably increased output can be attained without special plant, the author describes the results obtained in a plant of the following dimensions, without any special devices: The plant consisted of a low four-chamber system, in which the second and third chambers were 6 m. high and the first and fourth respectively 5·2 and 5·1 m. high. The first chamber was provided with an extension 7 m. in height for the introduction of the gases. The lead mantle of the Glover tower was attached directly to the stonework, the air-cooling being so efficient that little repair was necessary. This form of construction is only advisable in cases where the gases are free from fluorine and will not attack the stoneware. The Glover tower had a diameter of 3 m. and was 9 m. in height, and there were two Gay-Lussac towers. The burner gases containing about 7% by vol. SO₂ were forced by a wrought iron fan into the Glover tower at about 500° C., whilst there was a second fan of hard lead between the first and the central Gay-Lussac tower. As a rule the amount of circulating acid is equal to from 2 to 4 times the amount of acid produced, but in this plant the amount reached 1000% for the Glover tower and 500% for each of the two Gay-Lussac towers. The strong and weak nitrous vitriol were united and delivered together to the Glover tower. The direct consumption of nitric acid (36° B., sp. gr. 1·33) was 240 kilos., equal to 1·3%, referred to 100 kilos. of sulphuric acid (60° B., sp. gr. 1·71). In addition the circulating strong nitrous vitriol contained 1018 kilos. (1·1% 36° B., HNO₃) and the weak nitrous vitriol 278 kilos. (0·3% 36° B., HNO₃). The total quantity of nitric acid of 36° B. present was thus 1536 kilos., or about 8% of the sulphuric acid produced (18,500 kilos. of 60° B.). An advantage of the large volume of circulating acid was that an acid relatively free from arsenic (0·04 to 0·09%) was obtained. The gases leaving the Glover tower at 70° C. were heated by the reaction in the first chamber to 130° to 140° C. Drawbacks of this system are that the lead of the fourth chamber is strongly attacked, and that slight irregularities in working tend to cause the reaction to be delayed, to such an extent indeed that it takes place in the Gay-Lussac tower. Petersen's chamber regulator (*loc. cit.*) tends to prevent this, and the system may also be rendered more stable by cooling the acid from the Glover tower to about 60° C. before entering the Gay-Lussac towers, the conversion of the sulphur dioxide into sulphuric acid being effected more rapidly at a lower temperature (see Fr. Pat. 406,641 and Addition thereto; this J., 1910, 487, 627). Under these conditions the consumption of nitric acid of 36° B. is as stated, about 1·3% for the production of 100 kilos. of sulphuric acid of 60° B., or 1·04% for acid of 50° B. (sp. gr. 1·53).—C. A. M.

Sulphuric acid; Reduction of — by means of carbon monoxide. J. Milbauer. Chem.-Zeit., 1918, 42, 313–315.

SULPHURIC acid is reduced by carbon monoxide in accordance with the equation—

The reaction, which does not take place to any appreciable extent below 200° C., is not affected by the water which is produced, so long as the strength

of the sulphuric acid is not reduced below 91%. It is promoted by the catalytic action of many substances, notably lead, rubidium, iridium, selenium, ruthenium, silver, gold, and tin, but platinum, although acting catalytically, is also a "poison," and osmium and copper sulphate are inactive. The velocity of the reaction depends upon the concentration of the catalyst. Dilution of the carbon monoxide with nitrogen or with oxygen checks the velocity, and when the admixture reaches 50% the reaction is practically inhibited. This reaction explains the formation of carbon dioxide in Fownes and Rayleigh's method of preparing carbon monoxide by the interaction of potassium ferrocyanide and sulphuric acid (Proc. Roy. Soc., 1899, 62, 204). It also accounts for the fact that in the decomposition of secondary and primary carboxylic acids by hot sulphuric acid the liberated carbon monoxide is contaminated with sulphur dioxide.—C. A. M.

Ammonia; Effect of acetylene on the oxidation of — to nitric acid. G. B. Taylor and J. H. Capps. J. Ind. Eng. Chem., 1910, 10, 457–459.

The activity of the platinum catalyst is seriously affected when acetylene is present in the ammonia-air mixture; in the presence of 0.02% of acetylene the yield falls from 95% to 89%, or less, whilst with 0.1% of acetylene it falls to 65%. Acetylene and other non-reacting gases may be removed almost entirely from ammonia by absorbing the latter in water to form a concentrated solution, and then vaporising the ammonia by means of air.

—W. P. S.

Alkalis in silicates; The Lawrence-Smith method for the determination of —. P. Wenger and E. Brange. Monit. Scient., 1918, 8, 97–99.

In this method the finely divided silicate is heated with nine times its weight of a mixture of calcium carbonate and ammonium chloride (1:8); the alkalis are thus converted into chlorides. Investigation of the method showed that the decomposition of the silicate is complete after the mixture has been heated at 700° C. for 2 hrs.—W. P. S.

Oceanic salt solutions; Complete review of —. IV. E. Jänecke. Z. anorg. Chem., 1918, 103, 1–54.

A CONTINUATION of previous work (this J., 1918, 142 A). The equilibrium of the system $(Na-K-Mg)(Cl_2-SO_4)$

is further considered in relation to temperature. The equilibrium conditions are illustrated by numerous diagrams. (See also J. Chem. Soc., Sept., 1918.)—E. H. R.

Magnesium oxalate; Precipitation of —, and the theory of the formation of precipitates. A. Astruc and J. Camo. J. Pharm. Chim., 1917, 17, 381–386.

In the separation of calcium from large quantities of magnesium, the precipitation of the calcium oxalate should be made from very dilute solution. The tendency of magnesium oxalate to precipitate at the same time increases with the concentration of magnesium acetate, but is decreased by increasing quantities of oxalic acid and by the presence of ammonium chloride.—W. P. S.

Bismuth subnitrate; Determination of nitric acid in —. E. Luce. Bull. Soc. Chim., 1918 [iv.], 23, 264–271.

The nitric ion in bismuth subnitrate may be determined by using a modification of Delbourdeau's

method for nitrates. A solution is prepared containing 20 grms. of crystallised oxalic acid and 60 c.c. of concentrated sulphuric acid in 500 c.c. To 50 c.c. of this solution are added 1 gm. of manganese sulphate and 0.5 gm. of the bismuth subnitrate, and this mixture is heated on a water-bath for two hours under a reflux condenser, a slow current of carbon dioxide being passed through the flask during the whole time. The liquid is then thoroughly cooled, filtered, and made up to 100 c.c., and of this 50 c.c. is titrated with standard potassium permanganate (approx. 2%). The original oxalic acid solution is also titrated, and from the difference in the readings, the percentage of nitric acid in the bismuth subnitrate is calculated on the basis that one molecule of nitric acid oxidises three molecules of oxalic acid.—W. G.

Spent oxide; Analysis of —. Z. angew. Chem., 1918, 31, 45–46.

The following methods are used by the "Wirtschaftl. Vereinigung deutscher Gaswerke" and by the "Deutschen Gold- und Silber-Scheidanstalt" for controlling the sale and purchase of spent oxide. *Moisture, etc.* 25 grms. of the powdered sample is dried at 80° C. for about 4 hrs., or until the loss in weight between two successive weighings does not exceed 0.05 gm. *Sulphur.* 10 grms. of the dry sample is shaken occasionally during a few hours with 75 c.c. of carbon tetrachloride, then diluted with the solvent to 105 c.c., mixed, allowed to settle, and 50 c.c. of the clear solution is filtered into a small weighed flask, the filter washed with carbon tetrachloride, the contents of the flask evaporated, and the residue of sulphur weighed. *Ferrocyanide.* 10 grms. of the dry sample is shaken with 50 c.c. of 10% potassium hydroxide solution; after 16 hrs., the mixture is diluted to 255 c.c., filtered, and 100 c.c. of the filtrate is treated with 25 c.c. of hot ferric chloride solution (ferric chloride, 6 grms., hydrochloric acid, 20 c.c., water, to 100 c.c.). The mixture is heated at 80° C. for some time, filtered, and the filtrate agitated with 20 c.c. of 10% potassium hydroxide solution until the blue colour has disappeared. The whole is then diluted to 250 c.c., 1 gm. of lead carbonate is added, and after filtering, 100 c.c. of the filtrate is acidified with 5 c.c. of sulphuric acid (1:5), and titrated with copper sulphate solution which has been standardised against pure potassium ferrocyanide under the same conditions; ferric chloride is used as an external indicator.—W. P. S.

Halogens, sulphur, and nitrogen; Determination of — in the presence of mercury. M. François. Comptes rend., 1918, 166, 1000–1003.

For the estimation of halogens in mercury compounds the mercury is removed by means of zinc turnings by the method previously described (this J., 1918, 445 A), omitting the addition of potassium iodide. The filtrates and decanted liquids are mixed and in this solution the halogens are estimated by means of silver nitrate in the usual manner. Sulphur present as sulphide is first oxidised by bromine in hydrobromic acid as described (*loc. cit.*) and then, after the removal of the mercury by means of zinc, is precipitated as barium sulphate and weighed. For the estimation of nitrogen in mercuriammonium or mercuriamine compounds, the filtrate, after the removal of mercury, is made alkaline and distilled into dilute hydrochloric acid, and the nitrogen weighed as ammonium chloride or amine hydrochloride as the case may be.—W. G.

Determination of phosphoric acid as magnesium pyrophosphate. III. Magnesium tetra-ammonium phosphate. Balareff. See XXIII.

PATENTS.

Nitric acid; Concentration of —. Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. Ger. Pat. 305,915, Apr. 29, 1915. Addition to Ger. Pat. 278,867.

THE sulphuric acid employed for drying moist nitric acid vapour (see Fr. Pat. 465,504 of 1913; this J., 1914, 643) is more or less strongly cooled. For example, 80% sulphuric acid at 30° C. may be introduced at the top of the tower, and the quantity of the mixed nitric acid and steam is so regulated that the nitric acid vapour leaves the tower at about 95° C.—L. A. C.

Oxalic acid; Production of — by direct oxidation of alkali fusions of substances containing cellulose. A. Mensen, Neustadt. Ger. Pat. 303,166, Feb. 25, 1914.

HEATED air is blown through the melt which is stirred to obtain uniform and efficient oxidation and maintained limpid by the addition of water. Cooling of the mass is avoided, and the melt may have a depth of up to 1 metre, while the oxidation proceeds more vigorously than in the older process. —H. J. H.

Alkali metals or the like; Process for producing —. W. L. Morrison, Canonsburg, Pa., Assignor to Electric Reduction Company. U.S. Pat. 1,265,360, May 7, 1918. Date of appl., Aug. 17, 1916.

A COMPOUND of an alkali metal (e.g. basic silicate) is heated with a non-carboniferous reducing agent, under such conditions that the production of reaction gases is avoided as far as possible, and the alkali metal vapour is condensed and collected. The vapour may be burnt to form alkali peroxide. —C. A. K.

Aluminium compounds; Process for the manufacture of — poor in iron. Det Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank, Christiania, Norway. Eng. Pat. 112,948, Jan. 24, 1918. (Appl. No. 1403 of 1918.) Under Int. Conv., Jan. 24, 1917.

PLAGIOCLASE rocks of the labradorite-anorthite series or other raw materials rich in plagioclase are treated with dilute or concentrated mineral acids, e.g., 30–70% sulphuric acid, 25–60% nitric acid, or 10–30% hydrochloric acid, whereby solutions of salts of aluminium, calcium, and the alkali metals are obtained from which alumina is precipitated in the usual manner. Under such conditions the minerals rich in iron (e.g., hypersthene, diaspore, almandine, and epidote) are undecomposed, while the alumina of the plagioclase is dissolved. —L. A. C.

Aluminium compounds [and a fertiliser]; Production of —. H. Goldschmidt, Christiania, Norway. Eng. Pat. 113,276, Feb. 4, 1918. (Appl. No. 2019 of 1918.) Under Int. Conv., Feb. 2, 1917.

MATERIAL containing other metals (potassium, sodium, calcium) besides aluminium (e.g., plagioclase rocks of the series labradorite-anorthite, etc.) is treated with nitric acid and the mixture of nitrates thus obtained is heated, whereby the

hydrated aluminium nitrate is decomposed into aluminium oxide and nitric acid, the decomposition beginning at 140° C., and being complete at about 300° C., below which temperature other nitrates present undergo no decomposition. The aluminium oxide, produced in a form which is readily filtered, is separated by washing and filtering or decanting. Nitric acid is recovered from the escaping gases, and the solution of nitrates obtained by leaching the decomposition products may be used either for the production of a mixed fertiliser or for separation into different nitrates, or for the manufacture of nitric acid. The decomposition may be carried out under reduced pressure.—L. A. C.

Ammonium sulphate; Process of manufacturing —. T. Fujiyama, Tokyo, Japan. Eng. Pat. 116,321, May 31, 1917. (Appl. No. 7838 of 1917.)

AMMONIA gas and carbon dioxide are caused to act on a solution of sodium sulphate, whereby sodium bicarbonate is precipitated and a solution of ammonium sulphate is obtained. To the solution, containing traces of ammonia and dissolved sodium bicarbonate, sulphuric acid is added, drop by drop, until these are converted respectively into ammonium sulphate and sodium sulphate. By evaporating the solution (preferably above 100° C.) and cooling (preferably to below 0° C.), the sodium sulphate can be completely separated, ammonium sulphate alone remaining in solution.—L. A. C.

Cyanide; Manufacture of [alkali] —. G. Calvert, Twickenham Park, Middlesex. Eng. Pat. 116,365, June 12, 1917. (Appl. No. 8404 of 1917.)

IN the manufacture of alkali cyanide by the action of nitrogen and carbon on an alkali metal or salt in the presence of a catalyst (iron), effective distribution of the catalyst throughout the reaction mass is ensured by introducing it in the form of iron carbonyl vapour together with the nitrogen. The mixture of iron carbonyl and nitrogen may be prepared by passing air over coke to form nitrogen and carbon monoxide, and then passing the product over finely-divided iron to convert the carbon monoxide into iron carbonyl. A convenient form of apparatus consists of a horizontal iron retort, heated by a gas burner, in which briquettes of carbon and sodium carbonate are piled. Iron carbonyl is supplied into a distributing box at the top of the retort, whence it passes into the retort by numerous perforations. The supply pipe is lagged with insulating material to avoid decomposition of the iron carbonyl. Nitrogen is supplied by a pipe entering the retort at one end, the gaseous by-products escaping by a pipe at the other end. The escaping gases may be led into a flue or may be used again in the cycle of operations.—L. A. C.

Potassium chloride; Process for the manufacture of —. E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 116,438, Oct. 16, 1917. (Appl. No. 14,968 of 1917.)

POWDERED felspar (orthoclase) is heated in a retort or muffle to about 700°–900° C., and arsenic trichloride vapour is introduced into the retort, resulting in the formation of potassium chloride, arsenic trioxide, aluminium silicate, and silica. The arsenic trioxide vapour is condensed and may be used for the preparation of arsenic trichloride. The residue is lixiviated with water and the solution of potassium chloride decanted or filtered and evaporated to dryness. If iron is present, this is separated from the liquor by precipitation with calcium hydroxide; if sodium is present, the mixed chlorides are separated by crystallisation. —L. A. C.

Dialdehyde sulphylic acids; Production of —. A. Blinz, Berlin. Ger. Pat. 303,478, Nov. 3, 1916.

SALTS of monoaldehyde sulphylic acid in presence of acids, or the free acids themselves, are treated with an aldehyde, *e.g.*, formaldehyde, or sodium hydrosulphite in acid solution is treated with the proper quantity of an aldehyde, *e.g.*

Fullers' earth; Process for increasing the decolorising action of —. L. Kern, Hamburg. Ger. Pat. 304,076, Dec. 23, 1916.

THE crude earth is mixed with a dilute acid boiling about 100° C. or below, *e.g.* acetic, sulphurous, or nitric acid alone or mixed, and dried, whereby the product retains its porosity and low specific gravity. The decolorising action is influenced more by the organic than by the basic inorganic impurities.—H. J. H.

Hygroscopic substances; Production of crystals of —. Elektrochemische Werke G.m.b.H., Berlin, and Dreibrodtr, Blitterfeld. Ger. Pat. 304,087, April 27, 1917.

SUBSTANCES such as ammonium nitrate, sodium nitrate, calcium nitrate, and glycollic acid, when crystallised from solutions containing gelatin, egg albumin, casein, or dextrin, yield crystals with a colloidal coating and markedly diminished hygroscopic properties. The utility of ammonium nitrate for manurial and other purposes is increased. Crystals of sodium nitrate obtained in this way, owing to their double refraction, can be used instead of calc spar for optical purposes.—H. J. H.

Magnesium carbonate and pure carbon dioxide; Production of —. Chem. Fabrik Buckau, Magdeburg, and T. Silbermann, Halle. Ger. Pat. 304,681, Apr. 20, 1915.

MAGNESIUM sulphate in solution is treated with quicklime or burnt dolomite to precipitate calcium sulphate, and then with carbon dioxide under pressure to produce a solution of magnesium bicarbonate. After separating the calcium sulphate, the bicarbonate is heated to produce magnesium carbonate and pure carbon dioxide, which can be recovered.—H. J. H.

Magnesium hydroxide; Preparation of pure — from the magnesium chloride liquors of potash works. W. Kahn, Nordhausen. Ger. Pat. 304,682, Jan. 27, 1916.

THE combined sulphuric acid is first precipitated by an alkaline-earth sulphide or hydrosulphide and then magnesium hydroxide is precipitated from the resulting clear liquid by the same reagent. The hydrogen sulphide evolved is recovered.—H. J. H.

Magnesium hypochlorite; Manufacture of basic —. E. Merck Chem. Fabr., Darmstadt. Ger. Pat. 305,419, Sept. 1, 1916. Addition to Ger. Pat. 297,874.

MAGNESIUM oxide or hydroxide is treated with a solution of a hypochlorite, or a solution of an alkali or alkaline-earth is added to a solution of a magnesium salt containing hypochlorous acid. The process may be carried out by passing chlorine into a solution containing excess of magnesium oxide or magnesium hydroxide prepared as described above.

—L. A. C.

Hydrated zinc oxide; Manufacture of technical — free from chlorides. Bayerische A.-G. für chem. u. landwirts.-chem. Fabr., H. Hackl, and H. Bunzel, Heufeld. Ger. Pat. 305,738, Dec. 14, 1916.

THE basic salt precipitated by the action of strong bases on a solution of zinc chloride is separated from the liquor, then treated with milk of lime at the boiling point at atmospheric pressure, and washed. The operations are repeated several times, if necessary.—L. A. C.

Sulphur; Process for the separation of tar from —. Norddeutsche Präparaten-Fabr. Heydorn u. Biegel, Harburg. Ger. Pat. 305,418, July 4, 1917.

CRUDE, tarry sulphur is treated with a weak aqueous alkaline solution and then washed with water.—L. A. C.

Cyanogen compounds; Method for production of —. A. R. Lindblad, Ludvika, Sweden. U.S. Pat. 1,264,949, May 7, 1918. Date of appl., June 1, 1916.

SEE Eng. Pat. 107,426 of 1916; this J., 1917, 962.

Ammonium sulphate; Production of neutral —. F. Capron, London. U.S. Pat. 1,266,212, May 14, 1918. Date of appl., Sept. 17, 1917.

Preparation of readily soluble, soap-like washing tablets from water-glass. Ger. Pat. 305,461. See XII.

Process for manufacturing calcium arsenate for insecticidal use. U.S. Pat. 1,266,258. See XIXb.

VIII.—GLASS; CERAMICS.

Tempering of muffles for zinc extraction. Mühlhaeuser. See X.

PATENTS.

Glass plates or sheets; Manufacture of —. H. K. Hitchcock, Assignor to Hitchcock Experiment Co., Pittsburgh, Pa. Re-issue, 14,468, May 7, 1918, of U.S. Pat. 1,178,448, Feb. 16, 1915. Date of appl., Apr. 3, 1916.

AN apparatus for the manufacture of glass consists of a receptacle for the molten glass, and a drawing orifice with a continuous wall extending from within the glass to a point above the glass level, the area of the orifice gradually increasing from the bottom to the level of the glass so as to permit the surface from which the glass is withdrawn to lose heat by radiation. Means for drawing the glass upwards through the orifice and for regulating the temperature of the walls surrounding the orifice are provided. The restricted portion of the orifice may have the same shape as the finished article.—A. B. S.

Oven or furnace for baking earthenware. J. Litinsky, Elkins, W.Va. U.S. Pat. 1,265,097, May 7, 1918. Date of appl., July 1, 1916.

IN a three-storey, round pottery oven, the primary chamber occupies the middle storey and is separated from the one below it by a thin floor and ceiling through which pass short gas-flues. Fireboxes of the usual pattern are arranged on the circumference

of the middle chamber, and supplementary fire-boxes in the lowest chamber deliver hot gases through perforations in the floor of this chamber, and by means of vertical flues through perforations in the floor of the highest chamber. The two lower chambers may be worked with either up- or down-draught; the highest chamber with up-draught only.—A. B. S.

Silicon carbide articles; Method of producing —. O. Hutchins, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,266,478, May 14, 1918. Date of appl., Mar. 3, 1917.

A MIXTURE of silicon carbide with an organic binder, such as pitch, is moulded into a desired form and baked slowly, in the absence of air, to remove volatile matter, leaving a mass composed of silicon carbide in a matrix of carbon. This is heated to the temperature of formation of silicon carbide while exposed to vapours of silicon and silica, when the body is converted into a homogeneous mass of silicon carbide.—H. J. H.

Tunnel kiln for drying, firing, and cooling. J. Janka-Vales, Radotin, Bohemia. Ger. Pat. 304,016, Aug. 9, 1916. Under Int. Conv., Feb. 12, 1914.

THE kiln is two storeys high, the ware being dried on the wagon while passing along the upper storey and fired and then cooled in returning along the lower. A fan placed between the drying and the cooling chambers circulates air which passes under the firing chamber through a flue, the roof of which is formed by the floor of the waggon and thence back to the upper storey. Heat radiated by the waggon while in the firing chamber is thereby conducted to the drying room.—H. J. H.

Refractory material and process for making same. C. B. Stowe, Lakewood, Ohio. U.S. Pat. 1,265,545, May 7, 1918. Date of appl., Aug. 29, 1917.

ARTICLES formed of a mixture of magnesium carbonate and water, are coated with pulverised iron oxide and burned at such a temperature as to expel the carbon dioxide and water and to cause a partial combination of the iron and magnesium oxides. The iron oxide may be replaced by other metallic oxides.—A. B. S.

Burning bricks and the like; Method of —. S. G. S. Dicker, London. From Lambert Process Co., Chicago, U.S.A. Eng. Pat. 116,745, June 15, 1917. (Appl. No. 8602 of 1917.)

SEE U.S. Pat. 1,239,189 of 1917; this J., 1917, 1130.

IX.—BUILDING MATERIALS.

Cement clinker; Microscopical examination of —. Part II. T. Hattori. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 306—314.

TWO samples of cement clinker from a Dietzsch kiln, of similar composition, made from the same materials, A well burnt and B under-burnt, were examined. The alite grains in well burnt clinker from a Dietzsch kiln are intermediate in size between those of well burnt clinker from a stationary kiln and a rotary kiln respectively. The alite grains were large, with square or hexagonal section, in sample A, but were small and round in B. Eutectic structure was found to a much larger extent in the celite of A than in that of B. Celite, etched with alcoholic dilute hydrochloric acid, is seen under the microscope by reflected light to be composed of

white and grey areas, sharply divided and bounded by straight lines. The white area resists the etching reagent but the grey is readily attacked. The value of the hydraulic modulus, as calculated by well-known formulae, only holds good if there is an absence of free lime in the cement, but it is difficult to obtain commercial Portland cement which does not contain free lime. The hydraulic modulus of sample A was lower than that of B, nevertheless according to the microstructure the quality of A was better than that of B. Hence it is misleading to judge the quality of Portland cement by its hydraulic modulus, unless the effect of the presence of free lime be taken into account. (See also this J., 1918, 59 A.)—J. F. B.

Portland cement; Absorption of carbon dioxide by — on aeration. T. Hattori. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 297—305.

ABOUT 30 kilos. of Portland cement was placed in a wooden box, 60 × 60 × 20 cm., lined with sheet zinc, stirred every day, and analysed every two weeks for carbon dioxide and loss on ignition. The following results are recorded: Sample A, before exposure, carbon dioxide 0.40, moisture and combined water 1.10%; after 22 weeks' exposure, carbon dioxide 4.57, moisture, etc. 2.61. The results for sample B before exposure were 0.48 and 0.72% respectively, and after 22 weeks' exposure, 4.88 and 2.34%. Under different climatic conditions the same cements gave very much lower results. The graph showing the rate of absorption of carbon dioxide was a straight line.—J. F. B.

Reinforced concrete v. salt, brine, and sea-water. H. J. M. Creighton. Faraday Soc., July 23, 1918. [Advanced proof.] 8 pages.

THE deterioration of reinforced concrete when exposed to sea-water or saline solutions has been attributed to a number of causes, including electrolysis due to the action of a salt solution on the reinforcement. The author has found that when a bar of iron is immersed in a dilute solution of common salt, the salt hydrolyses, the hydroxyl ions uniting with ferrous ions which have passed into solution from the bar and forming undissociated ferrous hydroxide, which is gradually precipitated as a hydrated oxide; small quantities of hydrogen are evolved simultaneously. In this way the bar gradually disappears and hydrated iron oxide accumulates. As both iron oxide and the hydrated oxide occupy a larger volume than the iron from which they were formed, an expansive force is developed which is sufficient to crack the strongest concrete. The rate of deterioration is proportional to the porosity of the concrete. The author examined a number of reinforced concrete floors on which salt and brine solutions had frequently been spilled, and found, on the under sides, iron-stained cracks, which ran parallel to the reinforcing rods; from the larger cracks it was possible to remove iron oxide adhering to the corroded rods. In some cases the deterioration was very serious. In a number of tanks used for storing brine it was found that, after less than one year's use, the strength of the concrete was much below normal. In the prevention of this deterioration of concrete, the customary methods of waterproofing are far from satisfactory; the Schoop process, in which the concrete is coated with a film of metal by spraying, is more promising. Another protective measure, suggested by Gardner (this J., 1915, 431), consists in coating the reinforcement with a paint containing (a) boiled or bodied oils, oils which dry by semi-polymerisation, or oils which dry with a flat surface, (b) coarse pigments which are inert and non-conductors of electricity, preferably those of the

basic or chromate type. In addition, the cement used (especially in the construction of concrete ships) should be finely ground, low in alumina, high in silica, as free as possible from gypsum, absolutely devoid of free lime, slow in setting, and quick in hardening.—A. B. S.

PATENTS.

Fibrous [paring] composition and process for making the same. G. A. Henderson, St. Albans, W. Va. U.S. Pat. 1,265,655, May 7, 1918. Date of appl., Feb. 12, 1916. (See also U.S. Pat. 1,187,314 of 1916; this J., 1916, 813.)

A MONOLITHIC pavement material is made by mixing 40% of wood, shredded into bevelled, ragged-edged particles of substantially uniform thickness not exceeding $\frac{1}{4}$ in. and of irregular lengths and breadths between 1 in. \times $\frac{1}{4}$ in. and $\frac{1}{2}$ in. \times $\frac{1}{4}$ in., with 50% of wood shredded into sizes between $\frac{1}{2}$ in. \times $\frac{1}{4}$ in. and a cube of diameter equal to the thickness of the particles, and with 10% of wood in shreds varying between that of the largest cube to those of the average thickness.

The material is mixed *in vacuo* with a preheated bitumen of about 70 standard penetration, using about 50% in excess of that required in the finished product, and is then agitated whilst strongly heated to volatilise part of the bitumen and reduce its penetration to about 40, to cause the wood to swell and undergo partial distillation, whereby all moisture, sap-essences, cellular tissue, and pulpy matter may be expelled or destroyed and the pores of the wood impregnated with the molten bitumen. Then, on vibrating the container, the superfluous bitumen drains away and the particles of wood settle horizontally, after which the material is compressed so as to remove the excess of bitumen, leaving only sufficient to fill the pores, when subsequently contracted, to coat the shreds of wood, and to occupy the spaces between them and bind them together. The mass is then cooled and compressed gradually into the desired shapes.—A. B. S.

Wood; Process for fireproofing —. C. H. Teedale, Madison, Wis., and R. E. Prince, Elgin, Ill., Assignors to the Govt. and people of the United States. U.S. Pat. 1,265,549, May 7, 1918. Date of appl., Jan. 23, 1917. (Dedicated to the public.)

A PAINT consisting of zinc borate mixed with any other pigment and ground in a drying oil.—A. B. S.

Wood; Composition for preserving —. F. Peters, Berlin, Germany. U.S. Pat. 1,265,370, May 7, 1918. Date of appl., Nov. 13, 1914.

A COMPOSITION containing a dinitrophenol or a salt of a dinitrophenol with a monovalent metal, together with a soluble salt of an inorganic acid (such as chromic acid) incapable of attacking iron, and a fireproofing soluble salt.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Oxygen in iron. F. Schmitz. Stahl u. Eisen, 1918, 38, 541–542.

THE determination of oxygen in iron by heating drillings to redness in a current of pure, dry hydrogen gives only the amount which is present as iron oxide; occluded oxygen and oxides of other elements (manganese, silicon) are not affected. The apparatus recommended for the determination comprises a hydrogen cylinder from which the gas

passes in succession through two wash-bottles containing alkaline pyrogallol and one containing concentrated sulphuric acid, an unglazed porcelain tube containing fine iron drillings heated in an electric furnace, and two U-tubes containing phosphorus pentoxide. The purified gas then passes over the drillings of the sample to be analysed heated in a Mars electric furnace, and through a U-tube with phosphorus pentoxide and a sulphuric acid guard tube. Hydrogen is passed through the apparatus for an hour, after which the temperature of the furnace is raised to 850° to 900° C. in half an hour. The following results of oxygen estimations are given: grey cast iron, 0.001–0.005%; Swedish white iron, up to 0.002%; spiegel, 0.008–0.110%; silicospiegel, 0.037%; ferro-tungsten, 0.058%; high-speed steel, 0.021%; nickel-steel (0.45% C, 25% Ni), 0.020%; ingot iron, 0.031%; crucible steel (1% C), 0.24%; wrought iron, 0.217–0.214%. The oxygen content of basic steel just before the addition of the “killing” elements varied from 0.066 to 0.112%, while after these additions the oxygen present had fallen to 0.014–0.040%. The highest oxygen content ever found by the author in badly overblown basic Bessemer steel was 0.113%, corresponding to 0.51% FeO.—F. C. Th.

Basic Bessemer process; Non-removal of sulphur in —. L. Blum. Stahl u. Eisen, 1918, 38, 625–629.

CONTRARY to the experience of Hilgenstock (Stahl u. Eisen, 1893, 455), who found that on the average 58% of the sulphur present in the charge could be removed in the basic converter ($\frac{1}{10}$ th during the decarburisation, $\frac{1}{3}$ rd during the after blow and $\frac{1}{10}$ th by the manganese additions), the author only succeeded in removing one-third. With a mixer iron containing 0.4% Si 25% of the sulphur passed out of the metal, but when 1% Si was present this percentage was much reduced, and at times even an increase of sulphur occurred. This was traced to the lime added, which contained from 0.23 to 0.69% SO_2 . During the first minute or two of the blow, while the lime additions are being dissolved and the silicon is being oxidised, a silicious slag is formed and the following reaction occurs: $\text{CaSO}_4 + 4\text{Fe} = \text{FeS} + 3\text{FeO} + \text{CaO}$. As the lime additions become incorporated in the slag this sulphurisation stage passes into one of desulphurisation, which, however, can never be complete; it is most effective during the last few minutes of the blow. A high silicon content in the original charge results in a longer period during which sulphurisation can occur, with a corresponding reduction in the desulphurisation stage. A lime low in sulphur should be used. The percentage desulphurisation is higher as the sulphur content of the charge rises. It is not good practice from the point of view of desulphurisation to produce pig iron high in silicon merely to obtain more complete reduction of the manganese in the ore. The harmful effect of the silicon more than counterbalances any benefit derived from the manganese.—F. C. Th.

Steel; Influence of forging on the mechanical properties of —. G. Charpy. Comptes rend., 1918, 167, 12–14.

IN many French specifications a “coefficient of working” is embodied which is the ratio of the original section of the ingot to that of the finished article. In general a value of 3 to 4 is prescribed. To determine how far such a practice is sound, experiments were carried out on a pure medium-hard gun steel, on samples taken both longitudinally and transversely. Increasing the “coefficient of (hot) working” from 1.7 to 6.1 produced comparatively little effect on the tenacity or elongation.

in both transverse and longitudinal test-pieces, but the reduction of area, bending angle, and impact value were considerably influenced. In tests made upon the steel in a longitudinal direction, these properties were improved as the degree of hot rolling increased, but in the case of transverse test-pieces exactly the opposite effect was observed. With an increase from 1.7 to 6.1 in the coefficient, the value of the reduction of area fell from 76 to 31% and the impact value from 5.3 to 3.5 kilogram-metres. The influence of the hot working upon the properties of the steel in a transverse direction becomes accentuated in impure, segregated, or porous steels to such an extent that with a certain reduction of section the elongation and impact value fall almost to zero.—F. C. Th.

Electric steel; Triplex process of making —. T. W. Robinson. Amer. Iron and Steel Inst., May 31, 1918. Chem. and Met. Eng., 1918, 49, 15—20.

THE development of electric steel is based upon the fundamental conception that the electric furnace is pre-eminently adapted to the manufacture of the highest grade of carbon and alloy steels. Large-scale experiments in making steel by a duplex process, in which Bessemer blown metal was refined in a 15-ton basic-lined Heroult furnace, indicated that electric and open-hearth rails of like chemical composition had practically the same resistance to wear, and that the electric steel was rather more ductile. The duplex process necessitates removal of phosphorus in the electric furnace by the use of an oxidising slag, with subsequent deoxidation by a reducing slag, and while excellent steel can be produced by this practice, there is greater liability to irregularity than when the phosphorus has been eliminated previously. The triplex process is based on producing Bessemer-blown metal, with dephosphorisation in an open-hearth furnace, and final refining in an electric furnace. Close assembly of the various units is essential for rapid and economical practice. The Bessemer-blown metal is poured into a 65-ton ladle and the slag eliminated by nozzle pouring. Dephosphorisation is performed in three tilting open-hearth furnaces, each of which has a hearth area of 892 sq. ft. and is heated by producer gas or tar. The electrical plant consists of three 25-ton Heroult furnaces, with a combined output of about 12,000 tons per month, and experience has justified the erection of furnaces of large capacity. As soon as the steel is dead-melted the current is reduced until a proper pouring temperature is obtained. Stress is laid on careful manipulation of electric steels during and after pouring. Steel produced by the duplex or triplex process is strictly only electrically refined rather than electrically made, and the superiority of electrically produced steel lies in the pure heat of the electric furnace and the accurate control of the furnace atmosphere.—C. A. K.

Manganese steels as substitute for special steels for machine parts. T. János. Stahl u. Eisen, 1918, 38, 567—570.

The strength of steels containing 0.7—2.0% Mn increases for the forged state 2.3 kilos. per sq. mm. for each 0.1% Mn. The yield point of such steels melted in the crucible or electric furnace may reach 80—90% of the maximum stress compared with 50—60% in metal melted in the open-hearth furnace. The critical point on heating was determined by quenching a series of specimens of each steel at increasing temperatures and determining the Shore hardness numbers. For purposes of annealing the temperature was chosen which had given the

greatest hardness. The author concludes that as a war-time substitute for special steels in motor-car construction manganese steels containing from 0.7% to 1.6% Mn are the most satisfactory. They do not, however, reach the same high standard as the special steels. The steels need appropriate heat treatment.—F. C. Th.

Gold recovery; The sodium sulphide process of —. F. Wartenweiler. Bull. 166, Inst. Min. Met., July 25, 1918. [Advance copy.] 15 pages.

At the Prestea mine (Gold Coast), where the gold occurs together with arsenical and antimonial sulphides in quartz seamed with carbonaceous schist, the table concentrate is roasted, amalgamated, and cyanided; the tailing is classified into sand and slime, the latter being at present run to waste. The former is cyanided and then leached with 0.2% sodium sulphide solution. The gold thus dissolved is not precipitated by the carbonaceous schist; it is recovered by passing the solution through boxes filled with copper shavings. For cleaning up, the contents of the boxes are filter-pressed, dried, and screened through a 14-mesh sieve. The oversize is returned to the precipitation boxes; the undersize is at present roasted and sold for its gold and copper content. The increase in extraction due to sulphide leaching averages 2s. per ton of sand, with a sulphide consumption of 1.2 lb. An aluminium-zinc alloy (50:50), which is far superior to copper as a precipitant for gold, will be used as soon as market conditions permit.—W. R. S.

[Gold.] Pure zinc dust for precipitation. R. Wheeler. Eng. and Min. J., 1918, 106, 22.

CONTRARY to the views generally held, pure zinc dust (98—99.8%), as finely ground as possible, is as efficient a precipitant as the 90% product containing lead. The consumption of the pure dust is 30—40% less, while the gold bullion is purer and more easily refined.—W. R. S.

Copper cathodes; Oxygen and sulphur in the melting of —. S. Skowronski. Amer. Inst. Min. Eng. Eng. and Min. J., 1918, 106, 15.

WELL-WASHED cathode copper always contains 0.002—0.004% of sulphur as copper sulphate; the other source of contamination of the re-melted product is the fuel. When cathodes are melted under a coke cover, the sulphur content is higher and the conductivity lower than when a charcoal cover is used. It is pointed out that sulphur raises the "set," hence a certain amount of oxygen is required to depress it and so counterbalance the influence of sulphur. When the percentage of cuprous oxide in the bath is reduced by poling, the molten metal absorbs sulphur dioxide more easily with the formation of cuprous sulphide and oxide.—W. R. S.

Copper; Effect of boiling sulphur on —. C. R. Hayward. Chem. and Met. Eng., 1918, 48, 650—651.

SMALL cylinders of copper were immersed in boiling sulphur for periods varying from 5 mins. to 5 hours and the shell separated from the core of copper. The loss of copper increased from 15.4% in 5 mins. to 44% in 30 mins., 70% in 1 hr., and 100% in 4 hrs. The copper content of the shells varied from 77.12 to 78.02% (average 77.38%). It is thought probable that cupric sulphide acts as a carrier of sulphur from the bath to the metal. The formula most nearly corresponding with the material produced is $5\text{Cu}_2\text{S}_2\text{CuS}$, which contains 77.31% Cu.

—C. A. K.

Zinc industry; Research preparedness in the —.
P. C. Choute. Chem. and Met. Eng., 1918, 19, 20—22.

THE recent over-production of spelter, with consequent fall in price, emphasises the need for the study of efficient and economical treatment of complex zinc ores. Present processes of retort distillation with acid production and leaching are regarded as unsound, but leaching with electrolytic refining will survive owing to the demand for almost pure zinc. Electric furnace distillation has not extended rapidly because of the inefficiency of the process, but a radically different mode of electric smelting, in which the raw ore is treated directly at the mine, without previous roasting, will probably be successful. A process termed "volatile concentration" is advocated in which briquetted ore would be distilled in vertical retorts, heated by gas produced at the plant (preferably by the low temperature distillation of coal), the coke itself being used in the retort charge. Recuperation of waste heat from the retorts is effected by a flash boiler and hot blast stoves. Briquetting of the ore makes for economy in both carbon and zinc; 6% of pitch, 25% of carbon, and up to 10% of caustic lime are added, the lime reducing the zinc content of the residue to 1%. Irrespective of the complex character of the ore. Reversals of usual practice are suggested in that lead and silver are leached electrolytically from the raw zinc blende concentrates, and the sulphur is recovered in the elemental form from the calcium sulphide in the residue instead of acid being made from sulphur oxides in the roaster gases. Conservation of fuel and labour are claimed for each stage, but practical details are not furnished.—C. A. K.

Muffles for zinc extraction; Tempering of —.
O. Mühlbauer. Metall u. Erz, 1918, 15, 202—208.

BEFORE being built into the zinc furnace the muffles are tempered by gentle heat, to drive off the water of constitution of the clay without fusing the binding material. This is done in furnaces heated from below, the hot gases passing up side flues and then into the furnace at the top and away through holes in the floor. The air-dried muffles are packed in this furnace about 2 hours after the last charge has been removed, the door is luted up and the furnace left for about 15 hours, the temperature being distinctly higher than 100° C. The temperature is then gradually raised during 24 hours to 800° C., after which the muffles are removed to the zinc furnace. When tempered the muffles consist essentially of alumina and silica, resulting from the reaction, $Al_2Si_2O_5H_4 = Al_2O_3 + 2SiO_2 + 2H_2O$, together with small quantities of iron oxides, burnt gypsum, felspar, etc., which subsequently exert a beneficial influence as fluxes in closing the pores in the tempered muffle. The product should possess some considerable strength, withstand a temperature of 1300° C., and for a short period even 1600° C., and possess a fairly high conductivity for heat. In course of time, as the porous tempered muffle glazes over, the refractory nature of the material decreases, but the mechanical properties improve. The usual life of a muffle is 63 days.

—F. C. Th.

Zinc dust; Analysis of —. L. A. Wilson. Chem. and Met. Eng., 1918, 19, 32—34.

THE hydrogen evolution method is found to give the most consistent results for the determination of the metallic zinc content of zinc dust. A small conical flask is fitted with a separating funnel and an outlet tube connected through a two-way tap with a graduated measuring tube. 1 gm. of zinc dust is transferred to the flask, in which is also placed a

piece of sheet platinum and about 5 grms. of ferrous sulphate. The flask and connecting tube are filled with distilled water saturated with hydrogen, and the measuring tube completely filled with a 10% solution of sulphuric acid, also saturated with hydrogen. The system is now completely filled with liquid and ready for the generation of hydrogen. 30 c.c. of 1:1 sulphuric acid is slowly run into the flask from the separating funnel and the gas evolved, together with some solution and a small amount of zinc dust, passes over into the measuring tube, in which the zinc dust, coming in contact with the 10% sulphuric acid solution, dissolves completely. When the reaction is finished water is run from the separating funnel to drive all the gas from the flask into the measuring tube, and the volume of hydrogen is obtained at atmospheric pressure after levelling by means of the levelling bottle. Corrections for barometric pressure and temperature conditions are applied and the percentage of metallic zinc calculated. For a large number of routine determinations a correction tube similar to the measuring tube may be usefully employed.—C. A. K.

Zinc [in alloys]; Gravimetric and volumetric determination of — as zinc mercury thiocyanate.
G. S. Jamieson. J. Amer. Chem. Soc., 1918, 40, 1036—1039.

LUNDELL and Bee's method of estimating zinc in alloys as zinc mercury thiocyanate (Trans. Amer. Inst. Met., 1914, 146) is criticised. The factor for obtaining the weight of zinc should be 0.13115, not 0.1266, since the precipitate has the composition $ZnHg(SCN)_4$ after being dried at 102°—108° C. Excellent results are obtained by using ammonium thiocyanate instead of the potassium salt. Cadmium, cobalt, copper, bismuth, manganese, and mercurous compounds should be absent. Nickel in small amounts does not interfere appreciably. Ferric compounds in appreciable quantities should be reduced by sulphur dioxide. Arsenious compounds need not be removed. Instead of weighing the zinc mercury thiocyanate the following volumetric method, based on the equation: $ZnHg(SCN)_4 + 6KIO_3 + 12HCl = ZnSO_4 + HgSO_4 + 2H_2SO_4 + 4HClN + 6ICl + 6KCl + 2H_2O$, gives trustworthy results. The zinc mercury thiocyanate corresponding with 0.03—0.10 gm. of zinc is precipitated and washed, the filter containing the precipitate is transferred to an 8-oz. titration bottle, a thoroughly cooled mixture of 35 c.c. of concentrated hydrochloric acid and 10 c.c. of water, followed by 7—8 c.c. of chloroform, is added, and a solution of potassium iodate (19.644 grms. in 1000 c.c.; 1 c.c. = 0.00100 gm. of zinc) is at once added rapidly while the bottle is well shaken. When the iodine liberated in the first stage of the reaction has disappeared, the titration is continued slowly, the closed bottle being thoroughly shaken after each addition until the iodine colour has disappeared from the chloroform indicator, which marks the end-point. If more than 50 c.c. of the iodate solution is required, a further 10—15 c.c. of concentrated hydrochloric acid must be added in order to prevent hydrolysis of the iodine monochloride. (See also J. Chem. Soc., Sept., 1918.)—C. S.

Tin; Determination of — in wolfram ores and concentrates. A. M. Smoot. Eng. and Min. J., 1918, 106, 25—26.

TWO grms. of the finely powdered ore is digested with 100 c.c. of strong hydrochloric acid at about 50° C. for an hour, with frequent stirring. The liquid is then evaporated to about 50 c.c. and the evaporation continued, after addition of 5 c.c. of nitric acid, to about 15 c.c. The liquid is diluted with 100 c.c. of water, boiled a few minutes,

filtered, and the residue well washed with dilute hydrochloric acid, digested with 15 c.c. of ammonia, and the solution filtered through the same paper; residue and filter are ignited in an iron crucible, and fused with sodium peroxide. The product is leached, and the liquor acidified with hydrochloric acid and 5 grms. of tartaric acid and added to the original acid filtrate. The latter is treated with hydrogen sulphide, the precipitate separated and washed with very dilute sulphuric acid, ignited in an iron crucible, and again fused with peroxide. The melt is leached with water, acidified with hydrochloric acid, and the liquid treated with 5–6 grms. of pure granulated zinc. Before the latter is all dissolved the solution is rapidly filtered through asbestos, the sponge washed with water, returned to the beaker, and the metal dissolved by warming with 100 c.c. of hydrochloric acid (1:1). The liquid is transferred to a conical flask, reduced with nickel coils or iron wire in an atmosphere of carbon dioxide, cooled, and titrated with N/20 iodine solution.—W. R. S.

Metals; Testing of — by means of X-rays.
F. Janus and M. Reppschien. Stahl u. Eisen, 1918, 38, 508–514, 533–541, 558–564.

THE authors describe the physical nature, properties, and production of X-rays so far as these are required for the testing of metals. Hard rays produced from, for instance, a Coolidge tube of spark gap 27–42 cm. (equivalent to a potential difference of 180,000 to 240,000 volts) are best suited for the work. Blowholes have been detected in masses of steel 10–12 cm. thick. Visual examination with the fluorescent screen is not possible for sheets of metal thicker than 2 or 3 mm. Larger masses must be investigated photographically, with the aid of a calcium tungstate intensifying screen placed in close contact with the film. To minimise the disturbing effect of secondary radiations the sample should be surrounded by a layer of lead cast around it. This protection must be thicker as the sample increases in size; for very thick specimens a layer 15 to 20 mm. thick is required. For investigating special portions of metal secondary radiations are best excluded by placing a thick lead tube of sufficient diameter above the region with another shorter length between the specimen and the plate. This plate is made with a thick and very rich emulsion, which requires a much longer time of development than an ordinary plate, a glycine developer being recommended. A high tension step-up transformer giving 120,000 to 150,000 volts is far better than an induction coil as a source of current for the Coolidge tube. To minimise risk in such work the tube should be placed in a box with a thick lead lining and operated from another room, a small lead-glass window being provided for observation. The depth of flaws may be measured by making two exposures on the same plate with the tube moved horizontally a known distance. The distance apart of the two shadows then allows the depth to be calculated if the distance of the plate from the anti-cathode of the tube is known.—F. C. Th.

Gases in metals; Precision method for the determination of —. H. M. Ryder. Amer. Electrochem. Soc., May, 1918. [Advance copy.] 6 pages.

THE metal in the form of a thin ribbon is mounted in a water-cooled electric-lamp bulb, which is then evacuated. The temperature of the metal is then raised electrically in 50° C. steps to the fusion point, the gases evolved being immediately transferred by means of a diffusion pump to a second bulb. One or two cub. mm. of gas can be analysed in the special apparatus described, which is constructed entirely of hard glass, and has no stop-

cocks or rubber or cement connections. Water and carbon dioxide are first removed by cooling with liquid air, and are then determined by fractional vaporisation and measuring the vapour pressure with a McLeod pressure gauge in the case of carbon dioxide and with a mercury U-tube manometer with an optical lever attachment (Schrader, Amer. Phys. Soc., Dec., 1917) in the case of water vapour. Carbon monoxide, hydrogen, and methane are determined in the known manner by combustion, and nitrogen by difference. A silicon steel commenced to evolve considerable quantities of carbon monoxide at 500° C., and also of hydrogen and nitrogen at 730° C., which is the A2 point of this steel.—F. C. Th.

Metal spraying process; The Schoop —. H. Arnold. Z. angew. Chem., 1918, 31, 15–16.

THE specific gravity of metals sprayed with the Schoop apparatus falls as the distance of the object to be coated from the spraying device increases. Thus, taking the specific gravity of molten copper as 8.933, that of copper sprayed on a surface 3 cm. away is 7.823, at 10 cm. 7.51, and at 32 cm. 7.415. For zinc of specific gravity 6.922 in the molten state, the specific gravity of the metal sprayed at a distance of 8 cm. is 6.325, and at 42 cm. 5.903. Much better results are obtained with the Mauser "pistol" using already molten metal. The decrease of specific gravity is probably due to surface oxidation of the fine particles of metal; such oxidation occurs even if inert gases, such as nitrogen, are used for spraying, and is probably caused by oxygen produced by dissociation of water vapour.—F. C. Th.

[Ore] concentration; Dry sizing as a means of preparing feed for —. G. V. Bland. Eng. and Min. J., 1918, 105, 908–911.

A PROCESS of ore treatment is described involving dry sizing, followed by wet concentration. An increase of 20–25% in recovery at a relatively small cost has resulted. The main benefits derived from the dry sizing are:—control of pulp dilution; independence of all important concentrating units; greater efficiency of sizing machinery as compared to hydraulic; and greater efficiency of concentrating units on dry-sized feed.—F. C. Th.

Determination of molybdenum in presence of copper. Hoepfner and Binder. See XXIII.

PATENTS.

Open-hearth steel furnaces; Process for removing molten slag from — by means of air or steam blast. C. H. F. Bagley, Stockton-on-Tees. Eng. Pat. 116,663, Jan. 12, 1918. (Appl. No. 747 of 1918.)

MOLTEN slag is removed from the surface of a bath of metal by means of a blast of air or steam directed on to the surface of the metal in such a way as to blow the slag to one end of the furnace, whence it flows away through suitable outlets.—C. A. K.

Iron; Process for rendering — resistant to the action of organic acids, especially picric acid. C. Bunge, Witten. Ger. Pat. 303,126, Oct. 18, 1916.

IRON is treated with nitric, chloric, or chromic acid and washed with water, or oxygen is liberated electrolytically in contact with the iron. Iron rendered passive towards nitric acid is also passive towards picric acid, cresylates, and nitro-compounds. The process is applicable when the formation of picrates and picramates is undesirable, as in the components of shells and in shell-filling plant.

—H. J. H.

Iron ores containing manganese; Treatment of —. F. Wüst and R. Ruer, Aachen. Ger. Pat. 303,507, Apr. 24, 1917.

WREX iron and manganese are present in an ore as homogeneous mixtures—solid solution—they cannot be separated magnetically. The separation can be effected by treating the ore with a gaseous reducing agent under such conditions that only the iron is reduced and then smelting with fluxes so that pig iron is produced, while the manganese passes into the slag, which is worked up separately in a blast furnace to ferromanganese.—H. J. H.

Ferrophosphorus from iron phosphatic material; Process of making —. Process of producing ferro-phosphorus in electric furnaces. Process of producing phosphor-copper compounds. J. J. Gray, jun., Rockdale, Tenn. U.S. Pats. (a) 1,265,076, (b) 1,265,149, (c) 1,265,460, May 7, 1918. Dates of appl., Aug. 2, Oct. 13, and Dec. 28, 1916.

(A) CRUDE iron phosphate is mixed with a suitable fluxing material and excess of carbon, and heated in a blast furnace to reduce the phosphate to iron phosphide, with separation of the impurities as slag. The resulting ferrophosphorus is said to contain more than 15% P. (B) A mixture of subdivided phosphate rock with silica in excess and carbon is heated between 1000° C. and 1750° C. in a rotary furnace in contact with air, and the resulting ferrophosphorus is separated from the slag. (C) The method described in (B) is applied to the manufacture of phosphor-copper compounds from compounds containing copper and phosphorus, using air heated above 620° C.—C. A. K.

Alloys containing nickel; Manufacture of —. Stabilimenti "Blak" Ing. A. Pouchain, Assignees of P. Peynetti, Turin, Italy. Eng. Pat. 111,290, Nov. 5, 1917. (Appl. No. 16,131 of 1917.) Under Int. Conv., Oct. 23, 1916.

INSTEAD of making a direct addition of nickel in the preparation of an alloy, a nickel-zinc alloy of any suitable composition is used for admixture with the other constituents of the alloy. Homogeneous ingots free from blisters and oxides are said to be produced by this method.—C. A. K.

Metals; Electrically fusing and depositing —. E. H. Jones, London. Eng. Pat. 116,308, Apr. 12, 1917. (Appl. No. 5117 of 1917.)

AN electric arc is struck between the object on which the metal is to be deposited and an electrode comprising a mild steel containing all the materials necessary for the deposition of high-speed steel, covered by slag-forming material, such as asbestos yarn. For example, the electrode may consist of W 22, Cr 9, C 1.3, V 0.25, Fe 67-45%. By the use of these electrodes the cutting edges of high-speed or other tools may be renewed or the entire tool may be cast in a mould of the desired shape.—F. C. Th.

Copper tubes; [Electrolytic] production of —. S. O. Cowper-Coles, Sunbury-on-Thames. Eng. Pat. 116,509, Mar. 6, 1918. (Appl. No. 936 of 1917.)

COPPER is deposited electrolytically on a vertical rotating mandrel, the lower end of which is supported in a recess in a block of wood or other insulating material, the anode being of impure copper cast in the form of rough tubes or rings, or a cylindrical grid, supported concentrically with the mandrel.—B. N.

Annealing furnaces; Continuous —. Gibbons Bros., Ltd., and M. van Marle, Lower Gornal, Staffs. Eng. Pat. 116,605, Aug. 15, 1917. (Appl. No. 11,718 of 1917.)

FOR the annealing of brass or other metal tubes and bars, and of small articles which can be enclosed in tubes, externally heated, a retort is provided with cooled mouthpieces furnished with stuffing-boxes through which the tubes are pushed. Air is excluded from the retort by means of steam under pressure. A series of tubes of the same diameter may be connected together by double-ended plugs so that continuous movement may be effected, and steam may be admitted to or formed in the interior of the tubes so as to preserve a bright surface.—C. A. K.

Crucible furnaces. J. and G. Keith, London, Eng. Pat. 116,635, Oct. 20, 1917. (Appl. No. 15,254 of 1917.)

A SEPARATE receptacle to catch spilt metal from the crucible is provided beneath the furnace. It has a removable cover, and communicates with the lower part of the combustion chamber by a vertical pipe, the lower end of which is sealed by a lute on the cover of the catch pot.—C. A. K.

Hot blast stove. J. I. Lorimer, Joliet, Ill. U.S. Pat. 1,265,923, May 11, 1918. Date of appl., Mar. 6, 1917.

A NUMBER of passes in a hot blast stove is obtained by providing a dome at the top of the stove and a wall or combination of walls intersecting the space within the dome, and arranged at an oblique angle to the flow of gases so as to deflect them from one pass into the next pass.—C. A. K.

Heat treatment of metal objects; Process and apparatus for —. C. Napier, Assignor to Napier Saw-works, Inc., Springfield, Mass. U.S. Pat. 1,265,944, May 14, 1918. Date of appl., Jan. 21, 1918.

METAL objects are connected by temporary links of relatively considerable mass so as to form a chain which is drawn through a heated chamber and then subjected to suitable cooling conditions. The portions of the objects adjacent to the links are prevented from cooling rapidly and are hence left in the annealed condition.—C. A. K.

Ore crushing and amalgamating mill. D. W. Church, San Diego, Cal., Assignor to R. A. Dal-lugge, Los Angeles, Cal. U.S. Pat. 1,266,496, May 14, 1918. Date of appl., Nov. 22, 1916.

THE pan of a grinding mill of the edge-runner type is in the form of an annular trough having an inclined inner wall, and adapted to contain mercury. The edge-runners are supported above the bottom of the pan and away from the outer wall, so as to run only on the inclined inner wall, with freedom of movement in a vertical direction.—C. A. K.

Smelter smoke; Process for rendering innocuous. W. Küstermann, Burgörner. Ger. Pat. 302,996, May 1, 1914.

THE smoke is pumped through a bed of hot coke and then up a tower scrubber down which water, acid, or tar is sprayed. A curtain dipping into the liquid at the base of the scrubber forms a seal through which the smoke must bubble. The pump consists of a U-tube containing water which is caused to rise and fall by the motion of a piston in one limb.—H. J. H.

Metal electrode used in electric-arc deposition of metals. E. H. Jones, London. U.S. Pat. 1,265,453, May 7, 1918. Date of appl., Sept. 29, 1917.

SEE Eng. Pat. 109,652 of 1916; this J., 1917, 1135.

Lead; Extraction of — from its ores or lead-containing materials. H. L. Sulman and H. F. K. Picard, Assignors to The Metals Extraction Corporation, Ltd., London. U.S. Pat. 1,265,547, May 7, 1918. Date of appl., June 28, 1917.

XII.—FATS; OILS; WAXES.

Olive oil; Stability of —. E. B. Holland, J. C. Reed, and J. P. Buckley, jun. J. Agric. Res., 1918, 13, 353—366.

SAMPLES of a pure Californian olive oil were placed in glass bottles, some of which contained 5 c.c. of water, whilst from others moisture was excluded. In some of the experiments the oil was heated at 70° C. on successive days to destroy enzymes, if present. From an examination of the samples at intervals up to six years the following conclusions were drawn:—Air by itself causes slow destruction of the colour of olive oil, and slow production of rancidity and decomposition of unsaturated fatty acids, whilst light alone destroys the colour more rapidly than air, but has less effect in developing rancidity. The combined action of light and air has the greatest effect in destroying the colour, rapidly decomposing the unsaturated fatty acids, and producing rancidity, whilst it causes a slow but pronounced liberation of free fatty acids. Moisture has no effect on the colour and no appreciable influence on the development of rancidity, but it causes an oil to become turbid and yield a precipitate, and effects slow hydrolysis, with the liberation of a considerable amount of free fatty acids. The combined action of air and moisture, and of light and moisture is essentially that of the individual factors, whilst the combined action of the three factors is practically the same as that of the separate individuals, except that a greater proportion of free fatty acids is produced. Hence, to preserve olive oils in their natural condition it is essential to exclude air, light, and moisture as completely as possible.—C. A. M.

Castor oil; Determination of the purity of —. C. Frabot. Ann. Chim. Analyt., 1918, 23, 120—125.

THE author agrees with Chercheffsky (this J., 1918, 273 A) that the solvent power of petroleum spirit varies, but maintains that the determination of a foreign oil in castor oil by extraction with petroleum spirit (this J., 1918, 98 A) is sufficiently accurate provided that a control experiment with an oil mixture of known composition is made at the same time. Extraction with petroleum spirit has also the advantage that it enables the nature of the foreign oil to be determined.—W. P. S.

Pumpkin seed oil; Manufacture of —. E. W. Albrecht. Z. angew. Chem., 1918, 31, 132.

AT an oil factory in Roumania, sunflower seeds and pumpkin seeds have been employed with much success when the usual raw materials were scarce. A special kind of pumpkin is grown locally, which contains very many seeds and very little pulp, and which is used for feeding cattle and pigs. The seeds are always obtained in a very moist condition, and must first be dried thoroughly, then crushed between a pair of rollers and extracted with petroleum spirit. A yield of 40—42% of a green oil is obtained from the dry seeds, which is very suitable for the manufacture of soaps and solid engine greases; when refined it affords a good edible oil of pleasant flavour. In Hungary the pumpkin-seed oil is obtained by pressing. Sunflower seeds treated in the same manner yield 32—33% of oil; this oil is used for all industrial purposes, including the manufacture of varnish; in Russia it is largely employed as an edible oil. If the above seeds are to be treated by the pressing method, it is advisable to dry them very thoroughly and to remove the shells. The pressed cakes containing about 8% of oil are broken up and extracted by solvents.

—J. F. B.

Rancidity; Chemical tests for the detection of — R. H. Kerr. *J. Ind. Eng. Chem.*, 1918, 10, 471–475.

KREIS' test, which depends on the red coloration obtained when the fat is shaken with resorcinol dissolved in hydrochloric acid (see this J., 1901, 1001), is extremely sensitive, and its chief value is in detecting incipient rancidity which is not obvious to smell or taste. Issoglio's "oxidisability" method (this J., 1916, 898) yields less definite information, but it is useful as a confirmatory test. A low "oxidisability" value is not evidence of the absence of rancidity.—W. P. S.

Fats; Action of symbiotic bacteria on the constituents of — H. Pierry and P. Portier. *Comptes rend.*, 1918, 166, 1055–1057.

THE symbiotic bacteria isolated from the testicle of a pigeon oxidise glycerol giving a C₃-sugar, and also they cause the β -oxidation of butyric or β -hydroxybutyric acid. (See also *J. Chem. Soc.*, 1918, 1, 358.)—W. G.

Tussah chrysalis; Oil of the — S. Kobayashi. *Kōgyō-Kwagaku-Zasshi* (*J. Chem. Ind., Tokyo*), 1918, 21, 321–326.

TUSSAH silk is largely cultivated in Shantung, and the yearly production of chrysalis is estimated at about 48,000 tons. The author has examined the oil extracted by ether from the chrysalides, of an average weight of 5.8 grms. and the following composition: water, 80.41; crude fatty oil, 1.41 (7.2% of the dry substance); nitrogen, 2.66; ash, 1.23%. The oil had a clear, light brownish-red colour and the following characteristics: sp. gr. at 10°/4° C., 0.9263; saponification value, 185.6; acid value, 53.91; iodine value (Wijs), 124.21; refractive index (20° C.), 1.4763; butyro-refractometer reading (20° C.), 76.3. The m.p. of the fatty acids was 30.5°–32.5° C., and the amount of bromide insoluble in ether, 28%, m. pt. 178.5°–180° C. The unsaponifiable matter contained a sterol (possibly phytosterol) and a waxy hydrocarbon.—J. F. B.

Oil; Reaction of the aqueous medium in the enzymic hydrolysis of — Y. Tanaka. *Kōgyō-Kwagaku-Zasshi* (*J. Chem. Ind., Tokyo*), 1918, 21, 112–117.

IN 1910, the author showed that extracted castor beans, treated with acid and washed, showed a maximum lipolytic activity in neutral aqueous media, and that the function of the acid was to develop the enzyme from its zymogen (this J., 1910, 1259; 1912, 884). These results were further confirmed by Armstrong and Gosney (this J., 1913, 917). Recently Kita (this J., 1918, 312A) found that an activated lipase exerted its maximum effect in an acidified medium. It would appear, however, that Kita employed a lipase containing zymogen which had not been fully activated by the previous acid treatment, and that the acidity of the medium had a further action on the zymogen during hydrolysis. The author has repeated his experiments by triturating 100 grms. of pressed castor beans with 800 c.c. of N/10 acetic acid, washing and drying the residue. Hydrolysis of soya bean oil with this powder at 38°–39° C. in presence of increasing quantities of N/10 sulphuric acid confirmed the fact that the most energetic action took place in presence of pure water, and that the addition of small amounts of acid had a retarding influence proportional to the amount of acid present.—J. F. B.

Beeswax from Ogasawara (Bonin) Islands. S. Ueno. *Kōgyō-Kwagaku-Zasshi* (*J. Chem. Ind., Tokyo*), 1918, 21, 319–320.

THE author has examined the wax of *Apis mellifica* L., var. *ligustica*, from Ogasawara Islands. The

refined wax was light yellow in colour and more viscous than the Japanese and Korean varieties; the chemical characteristics were also different. The following data are recorded: Sp. gr. at 100°/4° C., 0.8096; m.p. (capillary tube method), 65.5° C.; refractive index (measured at 65° C. and reduced to 40° C.), 1.4518; reading in butyro-refractometer (ditto), 44.4°; acid value, 18.71; ester value, 70.03; saponification value, 88.74; iodine value (Wijs), 6.93.—J. F. B.

Determination of water [in soap, etc.] by distillation. Besson. See XXIII.

PATENTS.

Oils, fats, and the like; Apparatus for distilling — E. C. R. Marks, London. From Soc. Franco-Belge de Fours à Coke, Brussels. Eng. Pat. 116,309, Apr. 14, 1917. (Appl. No. 5290 of 1917.)

DISTILLATION of fatty or mineral or tar oils, etc., is effected in an apparatus containing one or more chambers through which circulate heating gases, each chamber containing a bundle of tubes provided with means for the admission of steam, and connected at one end with a box for the introduction of the liquid to be distilled, and at the other with a box for the collection of the distillate. By admitting gas from a furnace separately into each of a number of the chambers, the distillation may be carried out as a continuous fractionating process.—C. A. M.

Fats; Apparatus for and method of recovering — F. B. Dehn, London. From National Sanitary Service Co., Chicago, U.S.A. Eng. Pat. 116,384, July 3, 1917. (Appl. No. 9591 of 1917.)

FAT-CONTAINING liquids, and, in particular, slaughterhouse liquid refuse, is forced as a progressively accelerating transverse current beneath a larger quiescent volume of liquid, whereby the fat rises to the surface, whilst the solid impurities subside and are drawn off as a sediment. Apparatus for this process comprises a tank divided into two sections, each having an inlet at one end and an outlet, at higher level, at the opposite end. The first section, in which most of the sediment collects, contains an inclined deflecting plate between the inlet and outlet, and its lower portion is relatively larger than the upper. In the second section the entering liquid is forced by a baffle to flow along the sloping bottom, and then passes under another baffle at the opposite end of the tank and rises to the outlet. Both sections are provided with drain pipes controlled by valves.—C. A. M.

Catalyst [for hydrogenating oils]; Production of — from metal salts. Bremen-Besigheimer Oelfabriken, Bremen. Ger. Pat. 304,043, Aug. 18, 1912.

KIESELGUHR or asbestos is impregnated with a solution of a salt of nickel, e.g., the acetate, and a limited quantity of oil is incorporated with the mass, which is then heated in a vacuum at 150°–200° C. Hydrogen is passed through towards the end, and the mass is not only dried, but a portion of the volatile acid which would otherwise be set free during the reaction is removed. The resulting catalyst retains its activity for a long time.

—H. J. H.

Washing tablets from water-glass; Preparation of readily soluble soap-like — A. Kaufmann und Co., Asperg. Ger. Pat. 305,461, Oct. 15, 1916.

WATER-GLASS is heated with a small percentage of a salt which readily takes up water, e.g., anhydrous sodium sulphate, and the product formed into tablets.—L. A. C.

Soap; Process for deodorising —. C. Stiepel, Berlin-Steglitz. Ger. Pat. 305,702, Oct. 11, 1916.

A CURRENT of steam is passed under pressure into a solution of the soap at 200° C. or over until the issuing vapour is free from odour.—L. A. C.

Process for treating [decolorising] naphthenic acids. Ger. Pat. 305,771. See IIa.

Process for increasing the decolorising action of fullers' earth. Ger. Pat. 304,076. See VII.

Process and apparatus for treating soya beans. Eng. Pat. 116,153. See XIXa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oil varnishes; Colour designation of —. F. A. Wertz. J. Ind. Eng. Chem., 1918, 10, 475—476.

THE colour of oil varnishes may be satisfactorily matched by solutions of potassium bichromate in strong sulphuric acid (sp. gr. 1.84). For example, standards Nos. 2 to 10 of the 10-point scale used by varnish manufacturers may be represented by solutions of bichromate containing respectively 0.1, 0.25, 0.35, 0.5, 1, 1.5, 2, 4, and 8 grms. or more in 100 c.c. of sulphuric acid. The liquids are compared by transmitted light, in tubes of 1 to 2 cm. diameter, in quantities of not less than 2.5 c.c. Heating the solution to prevent deposition of chromic anhydride does not have any appreciable effect on the colour comparison.—C. A. M.

PATENTS.

Coating by means of emulsions; Process of —. B. Smith, Glens Falls, N.Y., Assignor to General Electric Co. U.S. Pat. 1,266,335, May 14, 1918. Date of appl., Nov. 6, 1917.

THE oil phase is separated from the water phase of an emulsion by bringing the emulsion into contact with a solid object heated to a temperature above 100° C.—J. H. P.

Varnish-gums; Process of melting —. O. C. Griem, Assignor to Berry Brothers, Detroit, Mich. U.S. Pat. 1,265,326, May 7, 1918. Date of appl., Nov. 17, 1917.

VARNISH gums are covered with water and heated until the particles are softened and flow together; the water is then poured off and the heating is continued until the gums are completely melted. The process ensures the protection of the particles of gum from the air during the former operation.

—D. F. T.

Process [paint] for fireproofing wood. U.S. Pat. 1,265,549. See IX.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Depolymerisation of raw —. K. Kawakami. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 226—231.

THE author criticises and points out inaccuracies in the experiments by Takeuchi (this J., 1918, 313 v), but he agrees with the general proposition that viscosity measurements may be of value in controlling the processes of manufacture. The viscosity is not an absolute function of the depolymerisation,

since it is affected also by the non-caoutchouc matters, e.g., proteins and rubber resins, which will not change in the same proportion as the caoutchouc. The degree of variation of the acetone extract during mastication falls within the limits of experimental error. The viscosity of raw rubber cannot be used as a sole measure of valuation, because there are several factors of value which have nothing to do with the viscosity of the solution; for instance, the amount of impurities and loss in washing, also the physical and chemical properties of the vulcanised products. The proper times of mastication obtained from Takenchi's curves, on the basis of an absolute viscosity of 0.1 in the rubber solution, work out at 40 mins. for plantation and 80—90 mins. for Brazilian Hevea, but these times appear far too long from a technical point of view.

—J. F. B.

Vulcanisation process; Investigations on the —. A. van Rossem. Communications of the Netherlands Govt. Inst. for advising the Rubber Trade and Rubber Industry. Internat. Assoc. for Rubber Cultivation in the Netherlands Indies, Part VI., 179—222.

RUBBER can be submitted to very considerable mastication without its rate of vulcanisation being appreciably affected, and in a mixing containing 32½% of rubber and 7½% of sulphur after various degrees of mastication, combination of sulphur and rubber occurred at the same rate, although the relative viscosity of the 5% solutions in benzene ranged from 177 to 63. The reduction of the breaking load and elongation observable after prolonged mastication of the mixing before vulcanisation is not due to alteration of the position of the stretch-strain curve, but only to a recession of the end-point of the curve. With the same mixing the quantity of sulphur which enters into combination is approximately proportional to the period of vulcanisation at any one temperature, whilst with mixings containing 2—10% of sulphur the percentage combined under a constant period of vulcanisation is approximately proportional to the original sulphur content. Between 130° and 150° C. the temperature coefficient for the vulcanisation process has a value between 2 and 3. Rubber showing a high viscosity number tends to give a stronger product than one of lower viscosity, not only because it suffers less depolymerisation under the same degree of working, but also because it vulcanises more rapidly. The resinous constituents of rubber are not essential to vulcanisation, although they appear to exert a slight acceleration on the process; their presence also causes a slight reduction in the breaking strength, which, however, may not be as great as the reduction due to the effect of the treatment necessary for their extraction. There is no proportionality between the percentage of nitrogen and the rate of vulcanisation of Hevea rubber. The introduction of inert fillers, such as powdered flint or pumice, does not alter the rate of combination with sulphur, but many basic compounds have a marked accelerating effect, whilst other substances, notably such as are acidic, have a retarding influence. Of *p*-nitrosodimethylaniline, piperidine, and a proprietary article consisting of a condensation product of acetaldehyde and ammonia, the first is the most effective accelerator with the standard mixing containing 7½% of sulphur, and the effect appears to be greater with rubbers of low viscosity. Raw rubber which has been heated for four hours in an atmosphere of carbon dioxide, when subsequently mixed with sulphur vulcanises more rapidly than a mixing made with rubber which has not been so heated; but no such difference is observable if the rubber is heated in air. A weak Hevea rubber of low viscosity by prolonged vulcanisation can be made to yield as strong a product as a strong

rubber, without danger of over-vulcanisation due to the longer duration of the process. Although the introduction of inert solid fillers does not appreciably affect the rate of combination of sulphur with rubber, it does affect the mechanical properties of the product, which is rendered somewhat stiffer, but the chief result is a decline in the elongation and strength at break. On the other hand soft fillers, such as paraffin wax, have an unfavourable influence on the mechanical properties of vulcanised rubber. When an accelerator, such as *p*-nitrosodimethylaniline, is used, not only is the rate of combination of the rubber with sulphur increased, but the product is stiffer and yields a stress-strain curve showing a decidedly reduced extensibility for the degree of vulcanisation attained, although with sufficient load it is capable of being stretched to an even greater extent than rubber vulcanised under ordinary conditions; with the use of additional catalysts, therefore, the coefficient of vulcanisation is no longer an indication of the probable course of the elongation curve. When rubber mixed with sulphur is heated for only a short time by steam under 50 lb. pressure, the product may be completely dissolved in the usual solvents, but the relative viscosity is greatly increased, a similar although less marked effect, greater than could be attributed to the mere "recovery" of the mixing, being observable on storing the mixing for several months at the ordinary temperature. On further vulcanisation the rubber becomes insoluble, the elongation at break attaining a maximum at a vulcanisation coefficient of approximately 2, rubber vulcanised to a less extent than this often being porous; when the coefficient exceeds 5 the effect of over-vulcanisation is observable, the rubber exhibiting brittleness when stretched, and for practical purposes with rubber-sulphur mixings a maximum coefficient of 2-4 is desirable, which is below that of maximum breaking load. When vulcanised rubber is stored at the ordinary temperature, the mechanical properties undergo considerable alteration without any appreciable concomitant increase in the amount of combined sulphur.—D. F. T.

PATENTS.

Latex; Processes and apparatus for drying coagulated and uncoagulated — and products obtained thereby. W. J. Mellersh-Jackson, London. From General Rubber Co., New York. Eng. Pat. 116,324, June 1, 1917. (Appl. No. 7899 of 1917.)

THE excessive foaming which occurs on attempting to dry latex under reduced pressure can be prevented by rendering the nitrogenous constituents of the latex insoluble prior to drying. This may be effected in a number of ways, such as heating the latex before or after coagulation to 80°-85° C.; treating the latex with suitable enzymes or ferments, such as rennet, or with chemicals which precipitate nitrogenous material. Antiseptics, *e.g.*, β -naphthol (0.2%), which aids in rendering the nitrogenous material insoluble, or sodium naphtholate, or pine-tar creosote dissolved in sodium cresylate (0.5%), or sodium fluoride (0.1%), may be added before or after insolubilisation. The latex or coagulum is then dried under reduced pressure on a series of trays in a current of air de-oxygenated by passage over burning charcoal.—E. W. L.

Rubber, rubber-like and similar vulcanisable material; Treatment of unvulcanised —. W. J. Mellersh-Jackson, London. From General Rubber Co., New York. Eng. Pat. 116,322, June 1, 1917. (Appl. No. 7885 of 1917.)

UNVULCANISED rubber, rubber-like or similar vulcanisable material is subjected to a vacuum, with or without heating, in order to remove moisture,

etc., and the vacuum is subsequently broken by the introduction of an inert substance, liquid or gaseous (*e.g.*, carbon dioxide, ammonia, hydrogen, or nitrogen), which fills the cells or pores of the substance, thereby preventing oxidation.—E. W. L.

Hard-rubber substitute; Method of making a — and the product thereof. P. Pickl, Assignor to E. Pickl, Chicago. U.S. Pat. 1,265,108, May 7, 1918. Date of appl., Apr. 23, 1917.

A SUBSTITUTE for hard rubber is prepared by heating claterite with 3-5% of resinous material and 2-3% of sulphur.—D. F. T.

Plastic composition [rubber substitute]. C. B. Wood, Charlestown, W. Va. U.S. Pat. 1,265,855, May 14, 1918. Date of appl., July 1, 1914.

SUELLAC is dissolved in strong alcohol to form a thick paste; this paste is poured on to fibrous material arranged in layers; the ingredients are thoroughly mixed together and subjected to pressure, and the pressed material is saturated with formaldehyde.—J. F. B.

Manufacture of plastic masses resembling horn or ebonite [from yeast]. Ger. Pats. 302,931, 302,930, and 303,133. See XV.

XV.—LEATHER; BONE; HORN; GLUE.

Application of leaves of Acer ginnala in Korea. Ueda. See VI.

PATENTS.

Leather; Dyeing or staining and mordanting of — [with titanium salts]. H. Wrigley, H. Spence, and P. Spence and Sons, Ltd., Manchester. Eng. Pat. 116,123, May 25, 1917. (Appl. No. 7522 of 1917.)

LEATHER is treated with a solution of titanate acid in sulphuric acid or hydrochloric acid in which the ratio of SO_3 is greater than 2 mols., preferably 1-9 mols. (or the equivalent of hydrochloric acid) to one mol. of TiO_2 . The operation is carried out at a dilution equal to about 1 part of SO_3 per 1000 of water, and the bath is heated to about 48° C. Example: Titanium sulphate containing 121 grms. of TiO_2 and about the same weight of SO_3 is dissolved in a mixture of 800 c.c. of strong sulphuric acid with 1 gall. of water, and the liquid is added to a bath of 200 galls. of water at 48° C. in which the skivers are agitated for about 30 mins., the completion of the action being judged by the colour.

—J. F. B.

Tanning animal hides; Process of —. Badische Anilin und Soda Fabrik. Ger. Pats. (A) 304,859, Mar. 14, 1915 (Addition to Ger. Pat. 281,484), and (B) 305,777, Feb. 9, 1915 (Addition to Ger. Pat. 290,965).

(A) PRODUCTS soluble in water and useful for tanning purposes are obtained by the introduction of sulphonic acid groups into naphthol pitch. (B) According to the main patent sulphonic acids of substances of high molecular weight are employed, which contain several benzene and naphthalene rings in their structure, also those containing such ring nuclei joined together with intermediate carbon atoms, provided they fulfil the following conditions: that they contain no phenolic hydroxyl and that they possess the property of precipitating glue and gelatin solutions. The addition patent provides for the use of products of this class which contain two or more aromatic nuclei, all or some of which are different from the others. Example: a condensation product of β -naphthalenesulphonic acid with benzyl alcohol.—J. F. B.

Leather substitute; Manufacture of a —. O. Steiner, Frankenberg. Ger. Pat. 304,497, May 12, 1917.

Nets made of spiral springs filled with cellulose are boiled in tar, dried, then coated with cellulose mixed with dissolved resin and finally dried under pressure. Belts and soles so prepared possess the pliability and tensile strength of leather.—J. F. B.

Plastic masses resembling horn or ebonite; Manufacture of — [from yeast]. H. Blücher, Leipzig, and E. Krause, Steglitz. Ger. Pats. (A) 302,931, Nov. 4, 1914 (Addition to Ger. Pat. 275,857), (B) 302,930, May 20, 1915, and (C) 303,133, May 12, 1916 (Additions to Ger. Pat. 289,597). (See also this J., 1915, 223, 972; 1916, 322.)

(A) YEAST or yeast residues are mixed with tar or tar oils, with or without the addition of aldehydes. Example: 1 kilo. of pasty yeast containing 15% dry substance, in which the yeast has been killed by heating, is stirred with 150 grms. of 40% formaldehyde and 15 grms. of tar. The mixture is dried, powdered, and pressed into heated moulds at 80° C. under a pressure exceeding 180 atmos. The tar may be replaced by anthracene oil. If desired 0.5% of washed and powdered sulphur may be mixed with the dried powder before pressing. (B) The yeast is previously dried and then treated with formaldehyde in the form of vapour, solution, or polymerised product. Substances are added which either take part in the reaction with the formaldehyde or serve merely as fillers; in the former case the substances may be previously treated by themselves with formaldehyde. The process of drying the yeast by heat induces certain changes in the proteins, so that the products have different properties from those formed by the action of formaldehyde on moist yeast. (C) Similar masses are prepared from beer sediments, the materials being ground, dried, and pressed under a pressure of 300 atmos. at 90° C.

—J. F. B.

Tanning hides; Method of —. G. Bosio and A. Peradotto, Turin, Italy. U.S. Pat. 1,266,203, May 14, 1918. Date of appl., Apr. 19, 1916.

XVI.—SOILS; FERTILISERS.

Organic matter in soils; Determination of — by the loss-on-ignition method. J. B. Rather. Bull. 140, Arkansas Expt. Stat. J. Ind. Eng. Chem., 1918, 10, 439—442.

ORGANIC matter in soils may be accurately determined from the loss on ignition of the sample after a preliminary treatment with a mixture of dilute hydrochloric and hydrofluoric acids to remove hydrated mineral constituents, carbonates, etc.:—One grm. of the soil, prepared in accordance with the official (American) method, is digested for 5 mins. with 50 c.c. of water in a platinum basin at 85° C., the aqueous extract decanted through an asbestos filter, with the aid of suction, and the residue digested with a second portion of 50 c.c. of water at 85° C. The united extracts are evaporated to a small volume, whilst the residue is digested with a mixture of 10 c.c. of 2.5% hydrochloric acid, 10 c.c. of 2.5% hydrofluoric acid, and 30 c.c. of water, the extract decanted through the asbestos filter, which is then transferred to the platinum basin containing the residue, and the digestion and decantation of the whole repeated five times. Finally the residue is washed with water, the concentrated aqueous extract added, the liquid evaporated to dryness, and the residue weighed, ignited, and again weighed. There is no appreciable loss of organic matter during the digestions.—C. A. M.

Phosphate rock; Agricultural availability of raw ground —. W. H. Waggaman and C. R. Wagner. J. Ind. Eng. Chem., 1918, 10, 442—444.

FIELD experiments under varying conditions over periods up to 5 years showed that the application of medium or large quantities of crude mineral phosphate (tricalcium phosphate) to most soils causes an increase in the yields of many crops during the first year of cultivation. The effectiveness of this form of phosphate as a fertiliser depends upon its being thoroughly distributed in a finely divided state, whilst the presence of decaying organic matter in the soil increases the effectiveness, probably owing to the greater bacterial activity and higher proportion of carbon dioxide under such conditions. For these reasons the effectiveness is usually increased after the rock phosphate has remained for a year or more in the soil. Acid phosphate (superphosphate) acts more rapidly than bone, basic slag, or crude rock phosphate, and is therefore probably the best form of phosphoric acid to use when rapid growth of the crop is the main consideration. To obtain the best results from natural phosphates, it is necessary to use a much greater proportion than is effective in the case of superphosphate, and the question whether an increased yield can be obtained more economically by the use of insoluble than of soluble phosphate depends upon the soil, method of cultivation, and other local conditions.—C. A. M.

Peat; Inorganic composition of a — and of the plant from which it was formed. C. F. Miller. J. Agric. Res., 1918, 13, 605—609.

THE peat examined was obtained from Florida from a very extensive deposit, ten feet deep, formed by the remains of saw grass (*Cladium effusum*) growing on the surface. The dried peat contained 7—10% of ash. On the assumption that the silica remained constant during the conversion of the grass into peat, it was calculated that seven parts of grass had yielded one part of peat. The percentage losses of the other constituents of the grass were: 12 of iron and aluminium oxides; 24 of lime; 41 of magnesia; 96 of potash; 84 of soda; 70 of phosphoric acid; and 33 of nitrogen.—J. H. J.

Dicyanodiamide; Determination of — in old nitrolim (crude calcium cyanamide). H. Kappen. Z. angew. Chem., 1918, 31, 31—32.

AN old sample of nitrolim examined by the author was free from cyanamide nitrogen. Determinations of the dicyanodiamide by Caro's and von Hager's methods (see this J., 1916, 974) yielded different results, the former giving 72.7% and the latter 82.2%. This difference was apparently due, at least in part, to the presence of urea in the substance. A trustworthy method for the determination of dicyanodiamide in the presence of urea is not, at present, known. (See following abstract.)

—W. P. S.

Calcium cyanamide with large percentage of dicyanodiamide or urea; Analysis of —. E. Hien and A. van Haaren. Z. angew. Chem., 1918, 31, 129—131.

WITH normal samples of cyanamide, Caro's method of analysis (this J., 1911, 23) gives satisfactory results, but in the presence of large proportions of dicyanodiamide and urea the results are liable to be erratic unless certain precautions are taken. The authors have obtained satisfactory results by the following procedure: A solution containing cyanamide, dicyanodiamide, and urea equivalent to about 0.2 grm. of nitrogen is diluted to about 200 c.c. and precipitated with 20 c.c. of 10% silver nitrate and 30 c.c. of 10% potassium hydroxide. The precipitate, which contains all the cyanamide

and dicyanodiamide and some of the urea, is washed, the filter is transferred to 150 c.c. of water, and the precipitate dissolved in the minimum quantity of nitric acid. The whole is diluted to 200 c.c.; 100 c.c. is treated with 2 c.c. of 10% silver nitrate with the addition of 15 c.c. of 10% potassium hydroxide. The precipitate, which contains the cyanamide and dicyanodiamide, is treated by the Kjeldahl process for the determination of nitrogen (N_1). The nitrogen of the urea may be estimated in the combined filtrates. In another sample the cyanamide nitrogen (N_2) is determined by precipitation with silver in a similar manner, using ammonia instead of potassium hydroxide. The urea may be determined more simply by a determination of the total nitrogen (N_3). Then $\text{urea} = N_3 - N_1$; $\text{dicyanodiamide} = N_1 - N_2$; $\text{cyanamide} = N_2$, all in terms of nitrogen. If the quantity of cyanamide is small compared with that of the dicyanodiamide the precipitation in presence of ammonia may be repeated.—J. F. B.

Sodium compounds; Action of — on wheat. J. A. Voelcker. J. Roy. Agric. Soc., 1916, 77, 262–264. Bull. Agric. Intell., 1918, 9, 552.

The sodium compounds used in the pot-cultures were the hydroxide, carbonate, chloride, and sulphate, the hydroxide being applied in solution and the others in the dry state. The different sodium compounds have very different effects both on the germination and the growth of wheat. The hydroxide and carbonate at first retard germination, but eventually have a beneficial effect, even when applied at rates up to $2\frac{1}{2}$ tons per acre. They cause an increase in yield of grain and in nitrogen content. Sodium chloride has a beneficial effect if used in quantities not exceeding 1 ton per acre, but is harmful to germination and production when used in larger quantities, and at the rate of $2\frac{1}{2}$ tons per acre may destroy the plant entirely. Sodium sulphate affects neither germination nor production, and may safely be used in quantities up to $2\frac{1}{2}$ tons per acre. Both the hydroxide and the carbonate cause "caking" and darkening of the soil, but the chloride and sulphate do not.—W. G.

Magnesium salts; Action of — on wheat. J. A. Voelcker. J. Roy. Agric. Soc., 1916, 77, 260–262. Bull. Agric. Intell., 1918, 9, 551.

The results of pot-cultures with spring wheat, the magnesium being supplied in the form of sulphate or chloride, indicate that the action of magnesium compounds on wheat varies very greatly with the salt used. The chloride may be used at rates up to 1 ton per acre, but in larger quantities it injures or totally destroys the crop. Magnesium sulphate may be used safely and advantageously up to 5 tons per acre. Increased nitrogen content, such as is obtained in cereals by the use of magnesium oxide, is not produced by magnesium sulphate.—W. G.

Magnesium carbonate; Injurious action of — on plants. H. Coupin. Comptes rend., 1918, 166, 1006–1008.

Water culture experiments with a number of different species of plants indicate that, apart from certain exceptional cases, magnesium carbonate is markedly injurious to plants. The injury, which varies slightly in intensity and character with the plant species, is indicated by diminution in the length of the principal root, considerable reduction in the number and size of the rootlets, the brown or blackish colour of the roots and rootlets, reduction of the number of absorbent hairs where these are formed, and by the lesser length of the aerial portion of the plant. In no case had magnesium carbonate any useful effect under the experimental conditions.—W. G.

Gas liquor; Use of crude — as fertiliser. Kayser. J. Gasbeleucht., 1918, 61, 121–123.

The growing shortage of supplies of sulphur in Germany necessitates the consideration of methods of making use of gas liquor other than in the manufacture of ammonium sulphate. With regard to direct application of the liquor as a fertiliser, the presence of plant poisons—thiocyanates, tar acids and bases, etc.—precludes its use as a top dressing. If the liquor is applied to the soil in the autumn, so as to allow a long interval before the time of sowing, it is possible that the harmful constituents are destroyed, but then the loss of nitrogen will be excessive. In the absence of definite experimental results caution is advisable.—H. J. H.

Spent oxide; Use of — as a fertiliser. J. Gasbeleucht., 1918, 61, 152.

The presence of sulphur and cyanogen compounds, which are plant poisons, seems to stand in the way of the use of spent oxide as a fertiliser. Still, in France it is applied to the land in considerable quantities, especially in connection with vine culture—probably on account of a destructive action on pests. Transport restrictions render its disposal in Germany difficult, and an outlet in agricultural operations is sought, especially in view of its small ammonia content.—H. J. H.

Phosphoric acid; Determination of citric-soluble — in superphosphates. P. Wagner. Z. angew. Chem., 1918, 31, 136.

HARTLEY'S method of replacing 2% citric acid by dilute nitric acid for the determination of citric-soluble phosphoric acid in superphosphates (this J., 1918, 384 A) gives, as a rule, considerably lower results. In 31 test experiments the amounts in the majority of cases ranged from 1 to 2% less than those obtained by the older method.—C. A. M.

PATENTS.

Soil-testing apparatus. M. O. Reiche, Milwaukee, Wis. U.S. Pat. 1,259,669, Mar. 19, 1918. Date of appl., Nov. 3, 1915.

A PORTABLE apparatus which can be used for estimating carbonates and humus in the soil and the acidity of the soil. In the case of alkali soils it can be used for estimating sodium carbonate in the soil.—W. G.

Fertiliser; Process of making a —. H. Blumenberg, jun., Los Angeles, Cal., Assignor to F. Blumenberg, New York, and J. J. Seeman, Los Angeles, Cal. U.S. Pat. 1,266,198, May 14, 1918. Date of appl., Jan. 22, 1917.

GROUND apatite, sodium nitrate, and an acid sludge containing sulphuric acid are heated together to liberate the nitric acid, and then further heated to 800° – 1000° C. The fused mass, consisting of aluminium, potassium, and sodium sulphates, is mixed with calcium nitrate and soluble calcium phosphate. The calcium nitrate and soluble calcium phosphate are obtained by treating rock phosphate with the nitric acid collected from the first process.—W. G.

Fertiliser and process of making the same. H. Blumenberg, jun., Los Angeles, Assignor to F. Blumenberg, New York. U.S. Pat. 1,266,199, May 14, 1918. Date of appl., July 16, 1917.

The claim is for a fertiliser consisting of a fused mass containing sodium nitrate and tricalcium phosphate.—W. G.

Production of aluminium compounds [and a fertilizer]. Eng. Pat. 113,276. See VII.

Preparation of crystals of hygroscopic substances. Ger. Pat. 304,087. See VII.

XVII.—SUGARS; STARCHES; GUMS.

[*Sugar*] *juice; Direct filtration of clarified [cane] — using Kieselguhr.* S. S. Peck. Rept. to Hawaiian Chem. Assoc., Oct., 1917. Intern. Sugar J., 1918, 20, 332—333.

DIRECT filtration of the entire limed juice should not only lessen the duration of the process of clarification, but should at the same time give a better quality of sugar and diminish the losses of manufacture. In a series of experiments carried out in Hawaii, using a Sweetland filter-press with a total filtering area of 860 sq. ft., the leaves of which were dressed with cotton drill, kieselguhr was added at the rate of 5 lb. per ton of cane to the first lot of juice so as to form a preliminary coating on the cloth, after which filtration proceeded continuously and satisfactorily. Allowing half an hour for "dumping" the press, and taking the average rate of filtration under these conditions as 2.98 gallons per sq. ft. per hour, the area necessary for direct juice filtration is 159 sq. ft. per ton of cane per hour, with 20 sq. ft. for re-pressing the cake, giving a total of 179 sq. ft. as compared with 199 sq. ft., the total area necessary when clarified juice and mud are handled separately. Similar trials carried out in several factories in Cuba are reported to have proved successful.—J. P. O.

Decolorising carbons; Vegetable —, and their use in the cane sugar industry. F. W. Zerbau. Louisiana Bull., No. 161, Feb., 1918.

CONTINUING the experiments recently described by Schneller (this J., 1918, 316 A), the author has found that highly active decolorising carbons can be prepared with the use of stannous chloride, which has about the same effect in this respect as zinc chloride; if magnesium chloride be used, a carbon is obtained that is 15 times as active as Norit (the decolorising power of which is 10—30 times that of animal charcoal). Investigations carried out at the Louisiana Experiment Station with the object of establishing the factory conditions most suitable for the utilisation of these decolorising preparations, showed that by far the greatest decolorisation results when clarification is effected with lime and phosphoric acid, as, e.g., when the juice is limed to neutrality, boiled, and filtered, treated with phosphoric acid and then with Norit, and again boiled and filtered; as little as 0.5% of the carbon produces a strong decolorisation, and 1% makes the juice practically colourless. Clarification with lime alone, with lime and sulphurous acid, or even with lime and sulphurous and phosphoric acids, gave less satisfactory results, the effect depending also to some extent upon the variety of cane from which the juice had been crushed. In addition to removing colour from the juice, the carbon at the same time increases the purity, improves the viscosity and rate of filtration, and slightly reduces the ash. Moreover, the decolorising effect, while considerable, is also permanent, and from the tests it is concluded that a greater yield of high-grade sugar is obtainable by the use of decolorising carbon than without it, or, in other words, that more molasses can be boiled back without impairing the colour and quality of the final product.—J. P. O.

Glucosazone reaction. I. D. Garard and H. C. Sherman. J. Amer. Chem. Soc., 1918, 40, 955—969.

THIS paper contains the results of a study of the glucosazone reaction. The authors find that phenylglucosazone melts at 208.0° C. (corr.) whether recrystallised from 60 per cent. alcohol or from pyridine. The yield of osazone from 0.2 gm. of dextrose obtained by heating together for one and a half hours 2.0 grms. of phenylhydrazine, 2.5 grms. of glacial acetic acid, and 1.307 grms. of sodium acetate in a volume of 20 c.c. was 76.95% and 76.7% of the theoretical in two experiments. With these quantities four 10 c.c. portions of water at room temperature will wash the precipitate sufficiently for analytical purposes. The maximum yield of pure product is obtained by heating for two hours. Longer heating increases the yield but causes decomposition. Within fairly wide limits a variation of the concentration of the sugar used has very little effect on the percentage yield of osazone beyond that due to the constant loss which results from the solubility of the osazone. An increase in the concentration of phenylhydrazine above about 2 grms. in 20 c.c. results in a rapid decrease in the yield of osazone. The acidity of the solution also has a marked influence on the yield, the range in which the reaction takes place being between $P_n = +4.0$ and 6.0; the maximum is about 4.7 and is best secured with acetic acid and sodium acetate. For the detection of minute amounts of dextrose, for instance 0.005 gm. in a total volume of 10 c.c., the best results are obtained with 0.4 gm. of phenylhydrazine, 0.5 gm. of acetic acid, and 0.5 gm. of sodium acetate. Maltose, dextrin, and lactose retard the formation of the precipitate but starch has very little effect. The reaction continues at least three hours.—W. G.

Sugar cane; Process and apparatus for macerating crushed —. C. McNeil, Glasgow. Eng. Pat. 116,521, May 14, 1917. (Appl. No. 6824 of 1917.)

THE sugar cane, after crushing, is again subjected to pressure and at the same time sprayed with water or weak juice, applied to it under such a head that it absorbs the full amount of liquid before it can expand to its full bulk and draw in air. This pressure liquid may be applied to the cane at the point in its travel where the maximum compressive pressure applied to it is just released. The operation may be performed by means of a fluted or serrated roller with loaded bearings and a box situated beneath the roller and perforated on the side adjacent to the roller, means being provided to force the liquid into the box and through the perforations on to the crushed cane passing under the roller; alternatively a trough is placed so that the box and part of the roller are so submerged that the crushed cane is soaked before it is subjected to the additional compressive pressure.—J. F. B.

Adhesive [from starch]; Vegetable glue or —. R. W. Tunnell, Philadelphia, U.S.A. Eng. Pat. 116,620, Sept. 6, 1917. (Appl. No. 12,800 of 1917.)

XVIII.—FERMENTATION INDUSTRIES.

Alcoholic fermentation; Formation of esters of phosphoric acid during —. A. Lebedev. *Biochem. J.*, 1918, 12, 87–92.

A MIXTURE of esters of phosphoric acid can be separated from a fermenting sugar solution, indicating that hexose-phosphate is not the only ester of phosphoric acid produced during fermentation. (See further *J. Chem. Soc.*, 1918, 1., 361.)—H. W. B.

Yeast; Nature of the proteolytic enzyme of —. N. Ivanov. *Biochem. J.*, 1918, 12, 106–119.

THE proteolytic enzyme of yeast consists of a mixture of peptase and protease. It is possible, by means of heat or the addition of a suitable activating substance, to inhibit the action of one of the component enzymes without affecting the activity of the other. (See further *J. Chem. Soc.*, 1918, 1., 365.)—H. W. B.

Wines; Composition of the fixed acidity of —. J. Laborde. *Ann. Chim. Analyt.*, 1918, 23, 127–132.

THE following quantities of non-volatile acids were found in normal red and white wines:—lactic acid, 1.06 to 1.95; succinic acid, 0.61 to 0.75; malic acid, 0.45 to 2.86; tartaric acid, 1.66 to 2.88%. Bad wines contained lactic acid, 2.24 to 2.40; succinic acid, 0.69 to 0.78; malic acid, 0.36 to 0.67%; tartaric acid, traces. Succinic acid is least attacked by bacteria. (See also this *J.*, 1918, 68A.)—W. P. S.

Wine; Detection of cider in [white] —. F. Mach and M. Fischler. *Chem.-Zeit.*, 1918, 42, 226.

THE method proposed by Medinger and Michel (this *J.*, 1918, 386A) for the detection of cider or perry in grape wines has been tested with various genuine wines from the Baden district, but was found not to be sufficiently sensitive or reliable for practical use. A definite result could not be obtained with less than 40% of cider, and in certain cases the genuine grape wine itself gave the reaction even more strongly than cider.—J. F. B.

Alcoholic beverages; Alterations in — after long storage. O. Reinke. *Chem.-Zeit.*, 1918, 42, 315.

A WELL-CORKED bottle originally containing either beer or wine and several centuries old was found in a wine-cellar. The contents were turbid and dark brown and contained yeast cells, cocci, and spores and mycelia of mould fungi. The liquid, which was acid and free from alcohol, contained 0.48% residue, 0.14% ash, 0.049% phosphoric acid, and 0.067% nitrogen. In the case of a partially filled bottle of champagne which had lain open on its side for 5 to 8 years, the contents were dark brown and flavourless, and contained spores, mycelia, etc., of *Aspergillus niger*. The filtrate was strongly alkaline and slowly produced hydrogen peroxide. It contained 0.27% total solids, 0.118% ash, 0.006% nitrogen, but no alcohol or sugar.—C. A. M.

Molasses; Manufacture of spirit from —. E. Galle. *Z. angew. Chem.*, 1918, 31, 3–4, 6–7.

IN the case of molasses containing raffinose, fermentation by beer yeast is the only applicable method of obtaining a satisfactory yield of alcohol; under certain conditions, mucilaginous gum-like substances may be formed during fermentation. Too large an amount of salts, or the presence of certain salts is another cause of bad fermentations. In practice it has been found that nitrites and fatty acids have a strong restrictive

influence on the fermentation. In several molasses stillerles ammonium phosphate is added to the yeast cultures to obtain a more vigorous growth. A fermentation test should be applied and the molasses stored and used separately according to the results. A quantity of molasses corresponding with 42 grms. of sugar as indicated by polarisation is diluted with 300 c.c. of water, neutralised with N/1 sulphuric acid, an additional 3 c.c. being added, and then treated with 30 c.c. of yeast culture which has been fermented down to 7 saccharimeter degrees. The flask is connected with Halden's apparatus, which has been charged with sulphuric acid and weighed, and the whole is immersed in water at 24° R. (30° C.), and weighed at intervals of 6 hours. A good sample of molasses should yield 0.5 gm. of carbon dioxide after 6 hours, 1.5 gm. after 12 hours, and at least 4 grms. after 18 hours. In accordance with the results of this test and the alkalinity, commercial molasses may be classified into the following groups:—(1) Alkalinity requiring up to 4 c.c. of N/1 acid per 100 c.c.; carbon dioxide in 18 hours, 4 to 6 grms. (2) Alkalinity, 5 to 8 c.c.; carbon dioxide, 3 to 4 grms. (3) Alkalinity, over 8 c.c.; carbon dioxide, less than 3 grms. The regulations of the Austrian Sugar Exchange prohibit the sale of acid molasses, but products which have undergone acetic or butyric fermentation are sometimes neutralised with soda or lime. Such products ferment badly, and yield volatile fatty acids when distilled with dilute sulphuric acid. For the fermentation of molasses a yeast acclimatised to hydrofluoric acid is the most suitable, but attempts to acclimatise beer yeast to hydrofluoric acid so as to ferment the raffinose have not proved successful. A suitable culture of yeast is prepared as follows:—About 10 grms. of good molasses is neutralised with sulphuric acid, diluted with water to 38° B. (sp. gr. 1.357), boiled, cooled, and after 48 hours boiled again. 170 c.c. of this liquid is treated with 70 c.c. of N/1 phosphoric acid, 10 c.c. of hydrofluoric acid (=2 c.c. of N/1 phosphoric acid), and 25 c.c. of a rosin soap solution prepared by boiling 100 kilos. of rosin with 20 grms. of potassium hydroxide in 500 litres of water, and diluting the solution to 4° B. (sp. gr. 1.029). The liquid is made up to a litre in a fermentation flask, and treated with 60 c.c. of pure yeast culture from a previous cultivation, which has fermented down to 7 saccharimeter degrees, the flask being immersed in water at 15° R. (19° C.), while a slow current of sterilised air is drawn through the liquid. After 24 hours the liquid will have fermented down to 7 saccharimeter degrees, and further cultivations are made from it in the same way, until eventually 500 litres is obtained, two-thirds of which is used for pitching the molasses. By carrying out the fermentation in stages, the yeast cultivation from one tun being introduced into a second tun, and so on, it is possible to ferment good molasses down to 6° in 12 to 14 hours, but it is essential to prevent the temperature rising above 24° to 26° R. (30° to 32.5° C.), or the yeast will degenerate. For the distillation of the wash Barbet's or Guillaume's combined distillation and rectifying apparatus is suitable. The residue from the still is evaporated to 42° B. (sp. gr. 1.41); and in Rueb's process for the recovery of nitrogenous compounds is distilled in an apparatus resembling a coke oven, or it may be consumed in a Parion or Gauer furnace, without recovery of the nitrogen.—C. XIXA.—FOODS.

Butter or oleomargarine; Detection of added colour in —. H. A. Lubs. J. Ind. Eng. Chem., 1918, 10, 436—439.

TWENTY grms. of the fat is dissolved in ether and the mixture is shaken with dilute sodium hydroxide solution; if the latter is coloured yellow, a vegetable colour is indicated. The presence of annatto is detected by filtering the alkaline solution, washing the paper free from alkali, and testing it with acid stannous chloride solution; a red coloration indicates annatto. Another quantity of 20 grms. of the fat is dissolved in 50 c.c. of petroleum spirit and the solution is shaken with 10 c.c. of a mixture of 1 vol. of sulphuric acid and 10 vols. of glacial acetic acid. Azo dyes impart a yellow, brown, red, or blue colour to the acid layer; annatto gives a green to brown colour, and turmeric a violet-red colour, but these two dyes are detected by the alkaline test. One or two pounds of the melted fat is then diluted with an equal volume of petroleum spirit, and the solution is shaken with about one-half its volume of a mixture of sulphuric acid 10, glacial acetic acid 90, and water 10 c.c. If Yellow AB or Yellow OB is present, the acid layer is coloured wine-red. The acid layer is then mixed with dilute hydrochloric acid and shaken with ether, which extracts Sudan I, II, and III, and Carminaph Garnet; Yellow AB and OB remain in the acid solution. The latter is then separated, diluted, neutralised, and extracted with ether; the ethereal layer is drawn off, washed with water, then with alkali solution, and evaporated to dryness. The residue obtained consists of Yellow AB or OB, or a mixture of both. Confirmatory tests may be applied to the residue.

—W. P. S.

Gluten; Hydration capacity of —. R. A. Gortner and E. H. Doherty. J. Agric. Res., 1918, 13, 389—418.

WEIGHED discs of gluten from different flours were immersed in solutions of lactic, acetic, boric, phosphoric, hydrochloric, and oxalic acids of various concentrations, with and without the addition of certain salts in 0.005 molar concentration. It was found that, notwithstanding the difference in their physical properties, the moist glutes from these flours absorbed almost the same amount of water. The results also showed that gluten from a "weak" flour has a much lower rate of hydration than that from a "strong" flour, and changes from a gel to a sol at a much lower degree of hydration. The hydration curves observed were of two types. Dilute solutions of hydrochloric and oxalic acids cause rapid absorption of water by the gluten, whereas somewhat stronger solutions of these acids extract water from moist glutes. On the other hand, in the case of lactic, acetic, and phosphoric acid, the use of stronger solutions causes only a slight reduction in the absorption of water by gluten. The relative hydration capacity of gluten immersed in acid solutions is reduced by the presence of inorganic salts, the glutes from different flours being differently affected, but the difference in baking properties between the glutes from "strong" and "weak" flours is not attributable to the acid and salt contents of the flours. The physico-chemical properties of the glutes from the different types of flour would not be identical, even if the flours had originally contained the same proportion of acid and salts. Neither can the different physical conditions of gluten be attributed solely to the presence or absence of an electric double layer surrounding the colloidal particles. It is suggested that the differences between "strong" and "weak" glutes may be due to the size of the particles, and that in the case of "weak" glutes a portion of the particles may approach more closely to the boundary line between the colloidal and crystalloidal conditions. A "strong" gluten has the emulsoid properties of a nearly perfect colloidal gel to a much greater extent than a weak gluten. (Compare T. B. Wood, this J., 1907, 1290; 1908, 175.)—C. A. M.

Alimentary preparations from blood and meat by means of yeast. A. Gauducheau. Comptes rend., 1918, 166, 1058—1059.

THE blood of pigs, bullocks, or horses is heated to coagulate the albumins and to disinfect it, then powdered, and fermented in slightly acid medium, in the presence of a small quantity of sugar, with brewer's yeast. A paste is obtained, which is porous and has a delicate aroma and may suitably be made into pasties or biscuits. Such a biscuit of fermented blood and flour constitutes a complete food.—W. G.

Canned foods; Influence of cold shock in the sterilisation of —. L. D. Bushnell. J. Ind. Eng. Chem., 1918, 10, 432—436.

RAPID cooling (blanching) immediately after heating is of no value in reducing the time required properly to sterilise tinned foods. The growth of bacteria is but little affected by the addition of small amounts of common salt, but a small quantity of acetic acid has a distinctly retarding action on the growth of bacteria in tinned vegetables. In many cases an unsterile product will keep indefinitely if sealed properly; sealing should not, however, be expected to take the place of a proper sterilising process.—W. P. S.

Proteins; Comparative study of the toxicity and nutritive power of alimentary — used in the pure state. F. Maignon. *Comptes rend.*, 1918, **166**, 1008—1010.

Feeding experiments with white rats indicate that fibrin, casein, and washed extracted meat powder, like egg-albumin, are incapable by themselves of supporting life, or of assuring no loss in weight even over a short period. Casein is the least toxic, then comes fibrin, and lastly egg-albumin, the meat powder being comparable with fibrin. In the case of casein and fibrin there is no seasonal effect as there is with egg-albumin. Further, when the two former proteins are fed, there is a deposition of fat in the liver, more marked with casein than with fibrin, whilst there is no fat deposition when egg-albumin or meat powder is fed. There is, therefore, an apparent correlation between the readiness of conversion into fat and the length of time over which the protein will support life.—W. G.

Antineuritic and antiscorbutic factors; Differential behaviour of the — towards adsorbents. A. Harden and S. S. Zilva. *Biochem. J.*, 1918, **12**, 93—105.

The antineuritic vitamin can be quantitatively removed from a solution containing antineuritic and antiscorbutic substances, e.g., a mixture of autolysed yeast and orange juice, by adsorption with fullers' earth, without altering the antiscorbutic power. Attempts to recover subsequently the adsorbed antineuritic vitamin in an active form from the fullers' earth have not yet been successful.

—H. W. B.

Cabbage; By-products of the fermentation of —. V. E. Nelson and A. J. Beck. *J. Amer. Chem. Soc.*, 1918, **40**, 1001—1005.

In ordinary commercial fermented cabbage (sauerkraut) the volatile acidity represents from 25 to 50% of the total acidity. The volatile acidity (equivalent to from about 86 to 122 c.c. N/1 H₂SO₄ per 200 grms. of sample) is due to acetic and propionic acids, the former preponderating, though in two cases formic acid was also found, and the fixed acidity to an inactive form of lactic acid. Alcohols, consisting entirely of ethyl and propyl alcohols, are present to about the same extent as volatile acids. Esters were only present in small amount, and 2.0—2.5% of mannitol was found.

—W. G.

Lupine seeds as a coffee substitute. M. Gonnermann. *Chem.-Zeit.*, 1917, **42**, 296.

LUPINE seeds which have been freed from bitter substances do not contain any alkaloid or saponin; the roasted seeds form a coffee substitute, and the author has used the latter for some months without suffering any ill effect.—W. P. S.

Action of symbiotic bacteria on the constituents of fats. Bierry and Portier. *See XII.*

Soya beans; Process of, and apparatus for treating —. T. W. Rees, and The Eastern Flour Co., Ltd., Staines. *Eng. Pat.* 116,158, June 8, 1917. (*Appl. No.* 8179 of 1917.)

SOYA beans are cleaned by spraying them with an alkali solution, and are then roasted, cooled, crushed, and freed from the husks by sifting or otherwise. The separated kernels are pressed to

remove all but 5 to 6% of the oil, and the press-cake ground to a flour, which may be mixed with wheat flour in suitable proportions. Automatic apparatus for carrying out this process includes a cleaning and brushing machine, a roasting chamber in which the beans are made to pass through a flame, a storage hopper and spraying device between the cleaning machine and the roaster, and means for cooling and crushing the beans, for separating the husks, and conveying the kernels to a press.

—C. A. M.

Meal or flour [from brewers' and distillers' grains], and method of obtaining and preparing same. J. Steeman, Stonehouse. *Eng. Pat.* 116,357, June 8, 1917. (*Appl. No.* 8218 of 1917.)

BREWERS' or distillers' grains are dried in a malt-drying kiln by means of a forced draught, being turned while drying, and are then winnowed or otherwise treated to separate the husks, which will be less broken up than when the grains are dried in a drying machine. The grain is then ground and the meal dressed to separate the residual husks, and, if desired, separated into two grades, one of which may be mixed with ordinary flour for human food, whilst the coarser grade may be made into dog biscuits.—C. A. M.

Milk-like food for the feeding of agricultural stock. W. J. Melhuish, Poole. *U.S. Pat.* 1,265,227, May 7, 1918. *Date of appl.*, Apr. 23, 1917.

See Eng. Pat. 101,264 of 1916; this J., 1916, 1078.

Drying apparatus for use in drying fruit, herbs, vegetables, seeds, chemicals, fibre, and the like. *Eng. Pat.* 116,606. *See I.*

XIXB.—WATER PURIFICATION; SANITATION.

Water; Softening of — by the lime-sodium carbonate and lime-sodium hydroxide processes. H. Noll. *Z. angew. Chem.*, 1918, **31**, 5—6, 9—11.

THE amounts of reagents required for softening water by the lime-sodium carbonate and lime-sodium hydroxide methods may be calculated from the total hardness and the carbonate-hardness, non-carbonate-hardness, and magnesia-hardness respectively. In determining the total hardness by Blacher's method with potassium palmitate solution (this J., 1912, 555), zinc and iron do not interfere with the process, as stated by Zink and Hollandt (this J., 1914, 803), provided they are first precipitated by means of sodium hydroxide. The carbonate-hardness is determined by titrating the water with standard acid, with methyl orange as indicator, and the magnesian hardness by the following modification of the method of Froboese (this J., 1915, 99):—100 c.c. of the water is rendered neutral to methyl orange with hydrochloric acid, then boiled for 10 mins., treated with 5 c.c. of a saturated solution of sodium oxalate, and again boiled for 1 to 2 mins. After the precipitate has subsided, the liquid is titrated with N/10 potassium palmitate solution, with phenolphthalein as indicator. The number of c.c. required multiplied by 2.8 gives the magnesian hardness in German degrees (one German degree = 40 mgrms. CaO per 100 c.c.). The carbonate-hardness multiplied by 10 gives the amount of lime in mgrms. per litre of water required to convert bicarbonates into carbonates, whilst the magnesian hardness multiplied by 10 gives the amount of lime (mgrms. per litre) required to convert the magnesium carbonate into hydroxide and magnesium chloride and sulphate into the corresponding calcium salts. The non-carbonate-hardness multiplied by 19 gives the amount of

sodium carbonate required (mgrms. per litre), but in practice it is necessary to add an additional 10 to 20%. As a rule water rich in salts requires a smaller excess than a water containing a small amount of salts. The same data are used for calculating the amounts of reagents required for the lime-sodium hydroxide process. In the case of a water in which the carbonate-hardness, excluding magnesian hardness, is greater than the non-carbonate-hardness, the latter multiplied by 1.43 gives the mgrms. of sodium hydroxide required per litre, whilst the sum of the carbonate and magnesian hardness, less the non-carbonate-hardness, multiplied by 10 gives the amount of lime required. To give the necessary excess of sodium carbonate the amount of sodium hydroxide should be increased and that of the lime reduced by quantities corresponding with 1° of hardness, and for this purpose sodium carbonate must be added to waters in which the carbonate-hardness does not exceed the non-carbonate-hardness by at least 1°. Where the combined hardness due to carbonates and magnesium salts is greater than the non-carbonate-hardness, whilst the carbonate-hardness is equal to or less than the non-carbonate-hardness, the amount of sodium hydroxide required is obtained by multiplying the non-carbonate-hardness by 1.43, and the lime by subtracting the non-carbonate-hardness from the sum of the carbonate and magnesian hardness and multiplying by 10. In the presence of magnesium bicarbonate in waters of this type, sodium carbonate should be added in a proportion corresponding with 1° (=19 mgrms. per litre). In the case of waters in which the combined carbonate and magnesian hardness is equal to the non-carbonate-hardness, the latter multiplied by 1.43 gives the required amount of sodium hydroxide. In this case no lime is required, and an excess of sodium carbonate must be added to the water. In the case of waters in which the combined carbonate and magnesian hardness is less than the non-carbonate-hardness, the sum of the carbonate and magnesian hardness multiplied by 1.43 gives the sodium hydroxide; the carbonate plus the magnesian hardness, less the non-carbonate-hardness, multiplied by 10, gives the amount of lime required; and the non-carbonate less the carbonate hardness, plus the magnesian hardness, multiplied by 19 gives the required amount of sodium carbonate. For softening alkaline water lime only is required.—C. A. M.

Nitrates in water; Detection of —. Escañch. J. Pharm. Chim., 1917, 47, 395.

THE nitrate is reduced to nitrite by means of amalgamated aluminium, the reduction requiring about 1 hour for completion. The nitrite is then detected by treating 15 c.c. of the water with 2 c.c. of 10% aqueous antipyrine solution, 4 drops of acid mercuric sulphate solution, and 1 drop of 5% potassium ferri-cyanide solution; a red coloration develops with as little as 0.1 mgrm. of nitrite per litre of water.—W. P. S.

Insecticides; Physical properties governing the efficiency of contact —. W. Moore and S. A. Graham. J. Agric. Res., 1918, 13, 523–538.

CONTACT insecticides may be divided into two groups: (1) those which "wet" the insect, owing to adhesion between the insecticide and the chitin which forms the outer covering of the insect, "spread" over the surface of the body, owing to the cohesion of the liquid being less than the adhesion between the liquid and the chitin, and pass into the trachea by capillarity; (2) those which "wet" the insect, but do not "spread" over the body owing to the cohesion of the liquid being greater than the adhesion between liquid and insect,

nor pass into the trachea by capillarity. Cockroaches and other insects were immersed in the liquid, previously coloured with Sudan III, or with trypan-blue, for periods of $\frac{1}{2}$ –2 hours, depending on the viscosity of the liquid. The insect was then removed and cut open, and the tracheae which had been penetrated were observed to be coloured either red or blue. Among the substances which penetrated farthest were fat solvents and the substances soluble in them, whilst aqueous solutions, except soap solutions, did not penetrate at all. The rate of penetration was governed by the viscosity. In the case of emulsions, spreading depended upon the character of the emulsifier and not on the emulsified substance. It was observed that fumigants gained entrance to the insect by way of the tracheae, and that volatile oils could enter either as liquid or vapour.—J. H. J.

PATENTS.

Sewage sludge; Air-lifts for [activated] —. T. Caink, Worcester. Eng. Pat. 116,580, July 7, 1917. (Appl. No. 837 of 1917.)

A VERTICAL pipe is arranged with its lower opening near the floor of the settling chamber, and its upper end is surrounded by an annular chamber having a weir at one side over which the sewage sludge flows to another chamber and thence to the aeration tank. Air is supplied through a small concentric vertical pipe having its lower end terminating in a porous diffuser, through which the air rises into the lift pipe, carrying the sludge with it. A gauge-tube is provided on the annular chamber, so that the height of liquid over the weir and consequently the rate of flow is indicated. The proportion of sludge is indicated by the amount of solid matter settling in the gauge-tube.—W. F. F.

Sewage; Purification and deodorisation of industrial —. C. Gunkel, Halle. Ger. Pat. 304,040, May 1, 1915.

THE sewage is first treated with chlorides or sulphates of alkaline-earths, e.g., with the waste liquors of potash works, and then with a mixture of highly plastic clay and the weathered detritus of silicate rocks as described in Ger. Pat. 248,980 (this J., 1912, 837). The process is specially suited to the sewage of textile and dye works.—H. J. H.

Carbon; Preparation of active — from sewage sludge. J. v. Kruszewski, Berlin-Pankow. Ger. Pat. 305,895, Oct. 21, 1913.

SEWAGE sludge is dried, mixed with a suitable alkali (e.g., lime), and the mixture subjected to dry distillation.—L. A. C.

Calcium arsenate for insecticidal use; Process for manufacturing —. J. K. Haywood, Washington, D.C. U.S. Pat. 1,266,258, May 14, 1918. Date of appl., Mar. 30, 1918. (Dedicated to the public.)

DICALCIUM orthoarsenate is prepared by the action of finely powdered limestone on arsenic acid. It may be used alone for certain insecticidal purposes, or it may be subsequently treated with a sufficient quantity of lime to produce tricalcium orthoarsenate, when it is suitable for use as an insecticide on foliage.—W. G.

Process for rendering smelter smoke innocuous. Ger. Pat. 302,995. See X.

Apparatus for and method of recovering fats. Eng. Pat. 116,384. See XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Antitoxin; Destruction of tetanus — by chemical agents. W. N. Berg and R. A. Kelsner. *J. Agric. Res.*, 1918, 13, 471—495.

EXPERIMENTS were undertaken to determine if possible whether tetanus antitoxin was of a protein or a non-protein nature. The antitoxin was submitted to the action of digestion preparations of trypsin and pepsin for periods up to 119 days. The progress of the digestion was controlled by determinations of the coagulable protein and amino-nitrogen. Any action on the antitoxin was detected by injecting the preparation together with tetanus toxin into a guinea-pig. It was found that the antitoxin was slowly destroyed by 0.5% sodium carbonate solution alone, without the protein being affected. Trypsin in neutral solution and in sodium carbonate solution digested both antitoxin and protein at the same rate. In 0.2% hydrochloric acid solution, antitoxin was destroyed in a few days, without any destruction of protein. Pepsin alone had no effect on the antitoxin, but pepsin-hydrochloric acid digested protein and antitoxin simultaneously. It is concluded that the antitoxin was of a non-protein nature, but that its stability was so closely related to that of the associated protein, that when the latter was broken down the antitoxin broke down with it.—J. H. J.

Broom; Presence of a fixed alkaloid in the common —. A. Valenr. *Comptes rend.*, 1918, 167, 26—28.

From the mother liquors obtained in the preparation of sparteine sulphate from *Sarothamnus scoparius*, the author has obtained a small quantity of a new alkaloid, *sarothamnine*, which readily forms crystalline compounds with various solvents, of which *sarothamnine-chloroform*, m.p. 127° C., $[\alpha]_D = -38.7^\circ$, and *sarothamnine-alcohol*, m.p. 90° C., $[\alpha]_D = -25.6^\circ$ are described. The alkaloid is an unsaturated compound, and to it the formula $C_{15}H_{24}N_2$ is provisionally assigned.—W. G.

Cotton plant; Chemistry of the — with special reference to Upland cotton. A. Viehoever, L. Chernoff, and C. O. Johns. *J. Agric. Res.*, 1918, 13, 345—352.

UPLAND cotton, *Gossypium hirsutum*, contains quercitrin and isoquercitrin, which have been previously isolated from other types of cotton plant, but does not contain gossypitrin and gossypetin. The ethereal oil isolated from Upland cotton differs from that found in the root bark of *G. herbaceum*. The greater part distils between 200° and 300° C., the lower fractions of the distillate being yellow to greenish-yellow, and the higher fractions light bluish-green to dark blue. The oil attracts the boll weevil.—C. A. M.

Phosphotungstates of certain bases and amino-acids. J. C. Drummond. *Biochem. J.*, 1918, 12, 5—24.

THE phosphotungstates of a large number of bases and amino-acids have been prepared in a pure condition and the solubilities in various solvents studied. The results indicate that the separation of the components of a complex mixture of bases and amino-acids is not likely to be readily effected by means of a process depending upon the relative solubilities of their phosphotungstates in various solvents. (See further *J. Chem. Soc.*, 1918, i., 236.)

—H. W. B.

Valerian root; Analysis of —. Ruyden. *Svensk Farm. Tidskr.*, 1917, 481. *J. Pharm. Chim.*, 1918, 17, 396—397.

TEN GRMS. of the powdered root is boiled for 1 hour with 100 c.c. of *N/2* alcoholic potassium hydroxide solution, then cooled, alcohol is added, if necessary, to make up the original weight, and the solution is filtered; 25 c.c. of the filtrate is distilled with the addition of 20 c.c. of 10% phosphoric acid and 75 c.c. of water, and 110 c.c. of distillate is collected. The distillation residue is then mixed with 25 c.c. of the alkaline alcoholic extract and 95 c.c. of water and the distillation repeated. The distillates are titrated with *N/10* barium hydroxide solution; 1 c.c. of the latter is equivalent to 0.0102 gm. of valeric acid. Valerian root yields from 2.91 to 4.77% of volatile acids (calculated as valeric acid), 13.1 to 26.9% of extractives, and 12.7 to 47.2% of ash. The high ash content of some samples is due to insufficient cleansing of the roots.—W. P. S.

Carbamides; Constitution of —. VI. Mechanism of the synthesis of urea from urethane. E. A. Werner. *Chem. Soc. Trans.*, 1918, 113, 622—627.

URETHANE undergoes gradual dissociation into ethyl alcohol and cyanic acid in the neighbourhood of its boiling point, and the hydrolysis of urethane by aqueous alkali is not a direct process but involves the intermediate formation of sodium cyanate, which undergoes subsequent hydrolysis to sodium carbonate. Similarly the formation of urea when urethane or ethyl carbonate is heated in solution with ammonia, is dependent on the intermediate formation of cyanic acid, which by combining with the ammonia yields urea; indeed, the ammonia resulting from the partial hydrolysis of the cyanic acid is sufficient for the reaction, and there is no need to add ammonia independently in order to obtain urea. The suggestion is made that two amino-groups, like two hydroxyl groups, cannot be stably attached to one carbon atom and that the $C(NH_2)_2$ grouping is probably absent from urea, thiourea, and guanidine.—D. F. T.

Guaiacol carbonate; Identification of —. A test for ether. G. Mane. *Pharm. Zeit.*, 1918, 63, 255—256.

ABOUT 0.02 gm. of the sample is dissolved in 1 c.c. of alcohol, 2 drops of ferric chloride solution and 1 drop of formaldehyde solution are added, and the mixture is poured on the surface of 2 c.c. of sulphuric acid; a cherry-red coloration, due to the presence of guaiacol, develops at the junction of the two liquids. Ordinary ether usually contains aldehydes and the latter invariably include formaldehyde, which is essential to the above reaction; consequently, when ordinary ether is substituted for the alcohol in the above test a positive reaction is obtained. Pure ether, such as is used for anaesthetic purposes and which must be free from aldehydes, does not give a coloration with the test. The sensitiveness of the reaction is about 1:300,000.

—W. P. S.

Glycerol; Decomposition of — in the presence of different catalysts: formation of ethyl and allyl alcohols. P. Sabatier and G. Gaudion. *Comptes rend.*, 1918, 166, 1033—1039.

GLYCEROL is dehydrated when passed over alumina at 350° C., the gaseous products being carbon monoxide, methane, and a little carbon dioxide, and the liquid products acrolein and higher aldehydes resulting from its crotonisation. Passed over finely divided copper at 230° C. the glycerol vapour is decomposed giving hydrogen and carbon dioxide mixed with some methane and carbon monoxide, together with ethyl and allyl alcohols and some of

the higher alcohols. Uranous oxide at 350° C. yields, from the glycerol, more ethyl alcohol and acrolein and less allyl alcohol, and the proportion of carbon dioxide in the gaseous products is increased. By hydrogenation with reduced nickel at 300° C. glycerol yields water and the following gases: hydrogen, methane, ethane, carbon monoxide, and carbon dioxide.—W. G.

Balsam of tolu; Evaluation of —. T. T. Cocking and J. D. Kettle. *Pharm. J.*, 1918, 101, 40—41.

THE most satisfactory method for the analysis of tolu balsam is to separate the aromatic acids by boiling with magnesium oxide and water, in the presence of a little xylene to soften the resinous matter. The magnesium salts of the aromatic acids are readily soluble in cold water, those of the resin acids being insoluble. For the determination of the free balsamic acids, 5 grms. of the balsam is dissolved in 25 c.c. of hot alcohol; 5 grms. of light magnesium oxide and 20 c.c. of xylene are added, and the contents of the flask well mixed; 100 c.c. of water is added, and the mixture boiled under a reflux condenser for one hour. After cooling, the whole is poured on a Buchner filter, the aqueous portion of the filtrate is separated, and the xylene, together with the magnesia and the filter paper, is returned to the flask. Boiling with 100 c.c. of water each time is repeated twice more; the mixed aqueous filtrate is washed once with ether, then acidified with hydrochloric acid, and the aromatic acids are extracted with ether and dried over sulphuric acid *in vacuo*. For the total balsamic acids, 2.5 grms. of the balsam is saponified by boiling with alcoholic potash, the greater part of the alcohol is evaporated off, the residue is dissolved in 100 c.c. of hot water and acidified with hydrochloric acid; 5 grms. of magnesium oxide and 20 c.c. of xylene are added, and the mixture is treated as before. The proportion of cinnamic acid in the balsamic acids is determined by the gain in weight on bromination. For the determination of the acid value of tolu balsam, 5 grms. of the sample is dissolved in about 50 c.c. of boiling alcohol, a large quantity of phenolphthalein solution (3—4 c.c.) is added, and the hot solution is titrated with N/1 alcoholic potassium hydroxide until the colour becomes dark brown but not red; it is then boiled under a reflux condenser for a few minutes to break up the precipitate, and the titration is completed. The variations found with a large number of samples indicated a range of 92.2—132.4 for acid value, 59.3—90.9 for ester value, 154.8—208.7 for saponification value, and 32.66—47.56 for total balsamic acids.—J. F. B.

Nitriles; Direct transformation of secondary and tertiary amines into —. A. Mailhe. *Comptes rend.*, 1918, 166, 996—997.

THE method used to transform di- and tri-isoamylamine into isoamylonitrile by passing their vapours over finely-divided nickel at 350°—380° C. (this *J.*, 1917, 1193) is shown to be generally applicable to secondary and tertiary aliphatic amines.—W. G.

Pennyroyal; Estimation of pulegone and other ketones in oil of —. C. T. Bennett. *Perf. and Essent. Oil Rec.*, 1918, 9, 208.

THE neutral sulphite process is the only practical method at present known for the estimation of the ketones in oil of pennyroyal, and the results include both the pulegone and the menthone. Experiments have shown, however, that the absorption in the case of pennyroyal is much slower than in the case of other oils, such as caraway and dill oils, and instead of one hour's shaking, at least three hours' must be given to obtain good results. For

instance, an oil showed 44% ketones after shaking continuously for one hour, 58% after two hours, and 82% after three hours. Another oil gave 50% after one hour and 88% after three hours. Parry's statement that oil of pennyroyal contains at least 80% of pulegone and other ketones is confirmed.

—J. F. B.

p-Cymene. I. Nitration. Mononitrocymene. C. E. Andrews. *J. Ind. Eng. Chem.*, 1918, 10, 453—456.

A YIELD of 85% of mononitrocymene was obtained when cymene was nitrated by mixing it with an equal volume of sulphuric acid, cooling to 0° C., and adding a mixture of nitric and sulphuric acids, the temperature being maintained at 0° C. Small quantities of *p*-toluic acid and *p*-tolylmethylketone were also formed during the nitration. On reduction, the mononitrocymene yielded the corresponding amine which, like the nitro compound, consisted of the 1.2.4-isomeride, i.e., 1-methyl-2-amino-4-isopropylbenzene.—W. P. S.

PATENTS.

Benzoic acid; Process for the manufacture of —. Weston Chemical Co., Ltd., London, and J. Savage, Runcorn, Chester. Eng. Pat. 116,348, June 7, 1917. (Appl. No. 8152 of 1917.)

TOLUENE (*e.g.*, 92 parts by weight) is chlorinated at boiling temperature until the liquid is of sp. gr. 1.11, the bulk of the product being benzyl chloride, with traces of benzal chloride and a free toluene. The crude product is boiled under a reflux condenser, for about 2 hours, with a quantity of caustic soda or milk of lime equivalent to the chlorine used (*e.g.*, 400 parts of 20% caustic soda). A solution of sodium or calcium hypochlorite (*e.g.*, 2030 parts of calcium hypochlorite containing 7% of available chlorine) is then added in the course of about 3 hours, and stirring is continued for another 3 hours, when the mixture is distilled until free from toluene. The residual alkali benzoate solution is filtered and benzoic acid precipitated by addition of hydrochloric acid.—L. A. C.

Diaryl sulphites; Production of —. Badische Anilin und Soda Fabrik. Ger. Pat. 303,033, Aug. 12, 1916.

AROMATIC compounds with hydroxyl groups in the ring—hydroxy-carboxylic acids excepted—are treated with thionyl chloride in presence of bases, *e.g.*, pyridine, which combine with hydrogen chloride without reacting with the thionyl chloride. The diaryl sulphites thus obtained—excepting diphenyl and ditolyl sulphites—decompose readily with the evolution of sulphur dioxide and are very reactive; hence their value as synthetic reagents, *e.g.*, for preparation of aromatic esters.—H. J. H.

p-Cymenesulphonic acid; Preparation of — from 2-bromo-*p*-cymene-3-sulphonic acid. Rheinische Campher-Fabrik G.m.b.H., Düsseldorf. Ger. Pat. 303,095, Aug. 18, 1916.

2-BROMO-*p*-CYMENESULPHONIC acid is treated with an aqueous alkali or alkaline-earth and zinc dust. This method is cheaper than the previous process, in which ammonia is used, and the necessity for working under pressure is avoided.—H. J. H.

Guaiacol; Process for the manufacture of —. E. H. Zollinger and H. Röhling, Berlin. Ger. Pat. 305,281, Jan. 23, 1916.

FREE catechol and alkali or alkaline-earth salts of methylsulphuric acid are heated in presence of veratrol as a diluent at 160°–180° C., with the gradual addition of a weak base, such as sodium carbonate or bicarbonate; a yield of over 85% of guaiacol is said to be obtained.—J. F. B.

Hydrogenised compounds; Manufacture of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 305,347, Oct. 5, 1915.

ISOCYCLIC or heterocyclic aromatic bases are hydrogenised by treatment with alkali metals or alkaline-earth metals and alcohols in presence of an indifferent solvent.—J. F. B.

Production of crystals of hygroscopic substances. Ger. Pat. 304,087. See VII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photomechanical printing plates; A development process without glycerin for the preparation of —. Schulz. Chem.-Zeit., 1918, 42, 277–278.

A CONSIDERABLE reduction of the cost of the developer for photomechanical printing plates can be obtained by the use of certain alcohols or, better still, of a saturated solution of a salt, such as magnesium chloride, instead of the glycerin normally used for reducing the effect of the developer on the exposed parts of the image; and by the use of a dilute mineral acid, preferably hydrochloric acid, instead of an organic acid, such as acetic acid. The developer containing mineral acid has also the advantage that the unexposed part of the colloid-chromate film is completely removed, leaving the metal, zinc or aluminium, quite bare, whereas the organic acid developer leaves a very fine film, apparently of metallic chromate, on the surface of the metal, which interferes with the subsequent inking processes.—B. V. S.

Testing of metals by means of X-rays. Janus and Reppchen. See X.

PATENTS.

Photographic paper. A. C. McCloskey, Philadelphia, Pa., Assignor of part to A. E. Davis and F. J. Geiger. U.S. Pat. 1,265,464, May 7, 1918. Date of appl., May 25, 1916.

PAPER is provided on both sides with a "ferro-undercoating" and with further coatings containing ferric salts on one side and ferrous salts on the other; or paper may be coated on one side only with either of these combinations.—B. V. S.

Printing surfaces; Method of producing —. O. Foerster, New York, Assignor of part to A. Jaeger. U.S. Pat. 1,265,641, May 7, 1918. Date of appl., Mar. 26, 1917.

A PLATE of glass or like substance is coated with a bichromated gelatin film containing a grain-producing substance, exposed to light, and the soluble parts removed. The hollows in the resulting film are filled in with a non-aethylic powder by a dusting process. A preliminary coating of bichromated albumin may be given, which is exposed from the back and the soluble parts removed before applying the bichromated gelatin.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

High explosives; Method of calculating comparative strength and efficiency of — from their composition and apparent densities. C. E. Waller. J. Ind. Eng. Chem., 1918, 10, 448–453.

THE "strength" and "efficiency" of high explosives are defined as proportional to the volume which the gaseous products of explosion of a unit weight (1 gm.) and a unit volume (1 c.c.) respectively of the explosives to be compared would occupy at the temperature of explosion, t° , and at atmospheric pressure. The temperature of explosion, t° , is calculated from the heats of formation of the ingredients of the explosive and of the products of explosion and the specific heats of the latter, and the volume of the gaseous products of explosion at t° is then calculated per gm. and per c.c. of explosive respectively. In analysing the products of an explosion, it is necessary to take into account the presence of substances, such as carbonates and bicarbonates of alkali metals, methane, etc., which are due to secondary reactions taking place on cooling. Only such reactions as have taken place up to the moment that t° has been reached should enter into the calculations of the strength and efficiency of explosives. When sulphur is present in explosives containing a deficiency of oxygen, part combines to form a sulphide (H_2S , Na_2S , etc.), whilst the remainder is oxidised and combines with the metal to form Na_2SO_4 , etc. The following table gives the calculated temperature of explosion, t° , and gas volume at t° per gm. of some of the more common explosives:—

Explosive	t°	Gas volume at t° per gm.
	$^\circ\text{C}$.	litres.
Nitroglycerin	3158	8.8328
Trinitrotoluene	2217	6.764
Picric acid	2599	8.727
Tetranitromethylaniline	3126	9.81
Tetranitroaniline	3238	10.55
Nitrostarch, 12.75% N	2205.7	8.168
Nitrostarch, 13% N	2277	8.28
Nitrostarch, 13.47% N	2415.4	8.1937
Mixture of—		
21.27% TNT and 78.73% ammonium nitrate	2310	8.2622
34% TNT	2195	8.3493
66% ammonium nitrate	2122	8.3315
41.77% TNT	2146	7.974
55.23% ammonium nitrate	3208	9.0424
58.6% TNT		
41.4% ammonium nitrate		
92% nitroglycerin		
8% nitrocellulose (12% N)		

An approximate idea of the expansion in c.c. resulting from the explosion of 10 grms. of an explosive may be obtained by multiplying the calculated gas volume at t° by 37.58. The results agree fairly closely with those found by the Trauzl test.—C. A. M.

PATENTS.

Blasting-powder. W. Treese, Silverton, Oreg. U.S. Pat. 1,265,975, May 14, 1918. Date of appl., Apr. 16, 1917.

A MIXTURE for use as a blasting explosive has the approximate composition:—yellow wax 13, soap stock 7, sulphur 21, nitre 11, potassium chlorate 22, and nitro-starch 26%.—T. St.

Process for rendering iron resistant to the action of organic acids, especially picric acid. Ger. Pat. 303,126. See X.

XXIII.—ANALYSIS.

Water; Determination of — by distillation. A. A. Besson. *Collegium*, 1918, 150—152.

THE substance to be examined (5—15 grms.) is heated with 200 c.c. of petroleum spirit, b.pt. below 170° C., in a wide-mouthed flask fitted with a Soxhlet-like apparatus having a side tube, but instead of the syphon the lower end of the body of the apparatus is constricted to a narrow tube graduated in tenths of a c.c. and sealed off at the lower end. The water and spirit distil off and condense into the wide body of the apparatus, and the water collects in the lower graduated part, where the quantity can be read off directly. The results agree with those obtained by direct distillation or drying *in vacuo*. The author gives data obtained with samples of cheese and soap.—D. W.

Cations of the so-called third and fourth groups; Petersen's method for the qualitative separation of the —. I. Bolin and G. Starck. *Z. anorg. Chem.*, 1918, 103, 69—72.

THE Petersen process of qualitative analysis (*Z. anorg. Chem.*, 1910, 67, 253) is found to be very satisfactory with the following modifications. After precipitation of the metals of the second group with hydrogen sulphide, sodium sulphate is used instead of sulphuric acid for precipitating barium and strontium. The precipitate is washed with hot water and the washings tested for calcium with ammonium oxalate. The residue, instead of being fused with sodium carbonate, is reduced by ignition with a little pure carbon. It is then dissolved in 4N acetic acid and examined for strontium and barium in the usual way.

For separating chromium from a mixture of hydroxides of iron, manganese, chromium, calcium, and magnesium, it is better to oxidise with sodium hypochlorite. When sodium peroxide is used, it cannot be completely washed out of the residue, and on acidification the hydrogen peroxide formed reduces manganese dioxide and the manganese, passing into solution with calcium and magnesium, is precipitated with the latter. For detecting zinc in the sodium sulphide precipitate, the latter is boiled with alkaline sodium hypochlorite, zinc and chromium passing into solution. The solution is acidified with acetic acid, the chromium precipitated as barium chromate, and the presence of zinc confirmed in the usual way. In the presence of oxalic acid the test for aluminium fails. The oxalic acid must be destroyed by boiling with 3% hydrogen peroxide and sulphuric acid. (See also *J. Chem. Soc.*, Sept., 1918.)—E. H. R.

Sodium and potassium [in organic substances]; Determination of —. S. N. Rhue. *J. Ind. Eng. Chem.*, 1918, 10, 429—431.

To determine sodium and potassium in organic substances, the sulphated ash of the sample is freed from phosphoric acid, iron, calcium, magnesium,

etc., and the residual sodium and potassium sulphates are weighed together. Potassium is then determined in a second portion of the ash by precipitation with platinum chloride, the iron, calcium, etc., having been removed previously. The potassium platinumchloride precipitate is washed with 80% alcohol, then with 20% ammonium chloride solution to remove calcium and magnesium chlorides, and again with alcohol. (See also *J. Chem. Soc.*, Aug., 1918.)—W. P. S.

Phosphoric acid; Critical elaboration of quantitative precipitation methods, exemplified by a method for the determination of —. H. Heidenhain. *J. Ind. Eng. Chem.*, 1918, 10, 426—429.

SOLUBILITY of the precipitate, its purity, and the influence of concentration, temperature, and presence of other substances are data which must be known before a precipitation method can be termed trustworthy. The author has investigated the determination of phosphoric acid, as phosphomolybdate, on these lines and recommends that the phosphoric acid should be precipitated as potassium phosphomolybdate in order to eliminate ammonium salts which would interfere when the precipitate is titrated subsequently. The precipitate is washed with 10% potassium nitrate solution containing nitric acid (the total solution should have an acidity not exceeding N/100); an allowance is made for the small amount of acid which remains in the precipitate and filter after the final washing. (See also *J. Chem. Soc.*, Aug., 1918.)—W. P. S.

Phosphoric acid; Determination of — as magnesium pyrophosphate. III. Magnesium tetra-ammonium diphosphate. D. Balareff. *Z. anorg. Chem.*, 1918, 103, 73—78.

WHEN magnesium ammonium phosphate is precipitated from a solution containing a large excess of ammonium chloride, especially if excess of ammonia is also present, it is contaminated apparently with the compound $Mg[(NH_4)_2PO_4]_2$. Attempts to isolate this substance have not been successful. Such contaminated precipitates, after calcination, contain magnesium metaphosphate, which is insoluble in hydrochloric acid. The metaphosphate is only slowly decomposed by heating with a blast flame, but more quickly than the pyrophosphate. It is suggested that magnesium tetra-ammonium diphosphate on heating undergoes decomposition, with the formation of ammonium phosphate, which dissociates, causing the result to be low through loss of phosphoric acid, part of which interacts with magnesium pyrophosphate to form metaphosphate. (See also *J. Chem. Soc.*, Sept., 1918.)—E. H. R.

Molybdenum; Determination of — in presence of copper. W. Hoepfner and O. Binder. *Chem.-Zeit.*, 1918, 42, 315.

IN Classen's method of separating molybdenum from metals of the copper group by digesting the ammoniacal solution with ammonium sulphide, a considerable amount of copper (up to 0.015 gm. per 100 c.c. of ammonium sulphide) may remain in solution and will be determined with the molybdic acid. To obviate this the copper should be precipitated electrolytically after acidifying the ammoniacal solution with sulphuric acid and adding nitric acid.—C. A. M.

Halogen derivatives of aromatic amines and their analysis. I. F. B. Dains, T. H. Vaughan, and W. M. Janney. *J. Amer. Chem. Soc.*, 1918, 40, 930—936.

AN account is given of the preparation of iodine derivatives from a number of halogenated anilines.

(For details, see J. Chem. Soc., Aug., 1918.) For the estimation of halogen in these and similar organic compounds, the following process is recommended. A small quantity (about 0.1 gram, or less) is dissolved or suspended in 30 c.c. of liquid ammonia in a Dewar bulb and small pieces of sodium are added, until a slight excess is present as indicated by the blue colour. The mixture is stirred and allowed to stand until all the ammonia has evaporated. Any excess of sodium is dissolved by addition of a small quantity of alcohol, water is added, the solution acidified with nitric acid, and a measured excess of $N/10$ or $N/40$ silver nitrate added. The solution is filtered and the filtrate titrated with standard ammonium thiocyanate using ferric alum as an indicator. Calcium was used with success in the place of sodium in the case of *p*-chloroaniline.—W. G.

PATENTS.

Velocity of a fluid and velocity of a body through a fluid; Measurement of —. I. Williams, Bristol. Eng. Pat. 116,385, July 4, 1917. (Appl. No. 9612 of 1917.)

ELECTRICALLY heated wires connected in series are arranged transversely across a tube through which fluid is passing. Thermocouples are arranged at both ends of the tubes with their junctions outside, and a connecting platinum wire is fused through the wall of the tube. The thermocouples are connected to a sensitive galvanometer so as to measure the temperature difference between the ends of the tube. The galvanometer may be graduated in terms of velocity of the fluid. The apparatus may be similarly used to determine the velocity of a body through a fluid.—W. F. F.

Gases of varying density; Apparatus for and actuated by — J. F. Simmance and J. Abady, London. U.S. Pat. 1,264,985, May 7, 1918. Date of appl., Nov. 25, 1912. Renewed Nov. 27, 1916.
SEE Eng. Pat. 27,484 of 1911; this J., 1912, 846.

Soil-testing apparatus. U.S. Pat. 1,259,669. See XVI.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Booth and Roberts. Furnaces, etc. 12,337. July 29.

Calvert. Apparatus for catalytic reactions. 12,323. July 29.

Carter and others. 12,457. See IX.

Drake and Gorham. Acid pumps for emptying carboys, etc. 12,320. July 29.

Dressler Tunnel Ovens, Ltd., and Rushton. 12,896 and 12,897. See VIII.

Hofmann. Apparatus for drying goods in bulk. 13,200. Aug. 14.

Hofmann. Mechanically-stoked furnace. 13,288. Aug. 15.

Iouides. Drying powdered material. 12,760. Aug. 6.

Jones, and Jones and Attwood. Apparatus for diffusing or supplying air in small globules. 13,391. Aug. 17.

Jorgensen. 12,980. See IX.

Kestner Evaporator and Engineering Co., and Reavell. Evaporators. 12,962. Aug. 9.

Lucas. Furnaces. 13,383. Aug. 17.

Pedersen. Separation of solid substances from liquid in which they are contained or suspended. 12,581. Aug. 1. (Norway, Sep. 13, 1917.)

Phillips. Tubular condensers. 12,845. Aug. 8.

Preville. Apparatus for raising acids, etc. 12,894. Aug. 8.

Thompson. Crucibles. 12,383. July 30.

Windram. Separating crystals from mother liquor. 13,137. Aug. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

9893 (1917). Ionides. Furnaces. (117,923.) Aug. 21.

11,039 (1917). Wilton, and Chemical Engineering and Wilton's Patent Furnace Co. Apparatus for treating gases with liquids. (117,843.) Aug. 14.

11,512 (1917). Wright. Art of drying materials. (117,704.) Aug. 8.

11,593 (1917). Rowlands. Apparatus for separating dust or powder from gases or air. (117,957.) Aug. 21.

16,423 (1917). Duodo. Evaporating and distilling apparatus. (111,480.) Aug. 8.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Aktiebol. Ingeniörsfirma Egnell. 12,483 and 12,588. See XXIII.

Anderson. Apparatus for producing oil fuel. 12,706. Aug. 3.

Anderson, Brady, and Deacon. Furnaces for distilling coal, etc. 13,221. Aug. 14.

Barrow, Scott, and Cadbury Bros. Suction gas producers. 12,759. Aug. 6.

Barton and Oddy. Purifying and decolorising hydrocarbons, etc. 12,992. Aug. 10.

Beccari. Oven for making charcoal and gas. 13,163. Aug. 13.

Beccari. Continuous action oven or pyre for making charcoal. 13,162. Aug. 13.

Bone. Treatment of fuels to improve their calorific value. 12,399. July 30.

Chapman Engineering Co. Gas-producers. 13,072. Aug. 12. (U.S., Apr. 20.)

Davidson and Liversedge. Gas-washers. 12,334. July 29.

Everett. Apparatus for treating carbonaceous materials. 12,875. Aug. 8.

Galecki. Apparatus for making solid combustible from vegetable earth. 12,829. Aug. 7.

Garrow. Carbonisation of coal, oil, shale, peat, wood, etc. 12,509. July 31.

Grylls. Carbons for electric arc lamps. 12,661 and 12,662. Aug. 2.

Hackford, Smith, and Pearson and Son. Liquid fuel. 13,285. Aug. 15.

Heise. Gas purifiers. 13,017. Aug. 10.

Heise. Gas generators. 13,018, 13,019, and 13,020. Aug. 10.

Helps. Manufacture, utilisation, and combustion of fuel. 13,256. Aug. 15.

Hill-Jones, Ltd., and Hughes. Manufacture of artificial fuel. 13,414. Aug. 17.

Hislop and Simpson. Gas manufacture. 12,955 and 13,404. Aug. 9 and 17.

Leadbeater. Treating peat to obtain carbon for decolorising. 13,111. Aug. 13.

Parsons and West. Oil-gas producer. 13,068. Aug. 12. (U.S., Aug. 16, 1917.)

Pearson. Distillation of shale, etc. 12,590. Aug. 1.

Phillips. Mechanical retorts or heating chambers. 12,846. Aug. 8.

Smith. Operation of water-gas plants. 12,694. Aug. 3.

Soddy. Separating and fractionating constituents of coal gas by means of charcoal, and improving absorptive power of charcoal for gases. 13,117. Aug. 13.

Tweedale. Manufacture of gas. 12,543. Aug. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

16,709 (1916). Helps. Utilisation and combustion of fuel. (117,637.) Aug. 8.

8139 (1917). Martin. *See* III.

8743 and 17,298 (1917). Turner. Processes of destructive distillation. (117,645.) Aug. 8.

9248 (1917). Ensulko Seito Takushoko Kabushiki Kaisha, Okada, and Miyake. Manufacture of decolorising carbon. (117,828.) Aug. 14.

9701 and 15,495 (1917). Hughes. Fuel from waste materials. (117,921.) Aug. 21.

10,703 (1917). Espenhahn. *See* VII.

10,759 (1917). Shilstone. Decolorising carbons and method of producing same. (116,253.) Aug. 8.

10,974 (1917). Wellington. Apparatus for destructive distillation of carbonaceous materials. (117,929.) Aug. 21.

11,745 (1917). De Dampierre. Manufacture of volatile oils such as petrol. (109,796.) Aug. 21.

12,625 (1917). Solari. Fuel for use in explosion engines. (109,802.) Aug. 8.

13,041 (1917). Turner. Gas-producer plant. (117,721.) Aug. 8.

16,272 (1917). Dyson. Liquid fuel. (118,021.) Aug. 21.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Barton and Oddy. 12,992. *See* II.

Perruche, and Gros et Bouchardy. Production of nitro compounds. 12,454. July 31. (Fr., Sep. 24, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

8139 (1917). Martin. Producing oils from sharp, middle, creosote, or similar oils. (117,914.) Aug. 21.

10,786 (1917). Dutt and Hamer. Purification of commercial benzol and toluol from thiophene and other similar compounds. (117,683.) Aug. 8.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATION ACCEPTED.

201 (1917). Oman. Preparation of azo colouring matters from ligninesulphonic acid or its salts. (103,822.) Aug. 8.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Albrecht. 13,251. *See* XXII.

Budde, and Hendon Paper Works Co. Means for separating cellulose from straw, etc. 12,392. July 30.

Courtaulds, Ltd., and Criggal. Squirting-nozzles for making strips, etc., from viscose, etc. 12,513. July 31.

Craig, and Spence and Sons. Treatment of textile fibres and fabrics, etc., to render them less inflammable. 12,442 and 12,683. July 31 and Aug. 3.

Grant. Waterproofing paper, etc. 13,165. Aug. 13.

Grolea and Waylor. 12,456. *See* XIII.

Harrison. Treatment of cotton yarns and fabrics. 12,436. July 31.

Partington. Pulp for making paper, etc. 12,930. Aug. 9.

Spicer, and Spicer and Sons. Treatment of parchmentised or vulcanised fibre. 12,663. Aug. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

201 (1917). Oman. *See* IV.

5769 and 14,675 (1917). Gillard and Heslam. Treatment of textile fabrics, wood, leather, etc. (117,640.) Aug. 8.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Harrison. 12,436. *See* V.

Hindle. Printing woven fabrics. 13,381. Aug. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

5769 and 14,675 (1917). Gillard and Heslam. *See* V.

12,509 (1917). Calico Printers' Assoc., and Fourneaux. Production of aniline black on vegetable textile fibres. (117,987.) Aug. 21.

12,510 (1917) and 3287 (1918). Calico Printers' Assoc., and Ashton. Mordanting vegetable fabrics and fibres. (117,715.) Aug. 8.

15,361 (1917) and 6685 (1918). Rydings. Applying starch or other adhesive to cops. (118,014.) Aug. 21.

1413 (1918). McComb and McComb. *See* XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Ashcroft. Dehydration of metal salts. 12,345. July 29.

Bithell. Apparatus for making hydrochloric, nitric, and sulphuric acids, etc. 12,728. Aug. 6.

Chance and Hunt, and Glidden. Manufacture of arsenic chloride. 12,965. Aug. 9.

Cox and Matheson. Treatment of alunite. 12,575. Aug. 1.

Distillates, Ltd., and Jarman. Separation of potassium and sodium salts. 12,646. Aug. 2.

Dixon and Harvey. 12,711. *See* XI.

Drake and Gorham. 12,320. *See* I.

Electrolytic Zinc Co. Treatment of zinc solutions preparatory to recovering zinc by electrodeposition. 13,368 and 13,369. Aug. 16. (Australia, Aug. 17, 1917.)

Harger, and Lever Bros. Manufacture of hydrogen, nitrogen, and carbon dioxide. 12,565. Aug. 1.

Hodgkinson. 12,881. *See* XXII.

Hodgkinson and others. 13,294. *See* XX.

Maxted and Smith. Removal of ammonia from high-pressure gases. 12,684. Aug. 3.

Maxted and Smith. Burner for oxidation of ammonia. 13,037. Aug. 12.

Preville. 12,894. *See* I.

Silberrad. Manufacture of salts. 12,757. Aug. 6.

Soc. Gros et Bouchardy. Production of nitrogen dioxide. 12,453. July 31. (Fr., Aug. 20, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

12,946 (1915). Devaucelle. Manufacture of cyanides and ammonia. Aug. 21.

5063 (1917). Howorth (Norsk Hydro-Elektrisk Kvaestofaktieselskab). Treatment of nitrate of ammonia. (117,823.) Aug. 14.

9347 (1917). Freeth. Manufacture of sulphuric acid from nitre cake. (117,649.) Aug. 8.

10,703 (1917). Espenhahn. Recovery of cyanogen-bearing compounds from coal gas, etc. (109,254.) Aug. 21.

11,224 (1917). Levin. Manufacture of metallo-pyrophosphoric acids or their salts associated with boron compounds or containing boron, and application of the products to tanning. (117,693.) Aug. 8.

11,256 (1917). James, Vint, and Alexander. Apparatus for separating nitrogen and oxygen from liquid air. (117,937.) Aug. 21.

12,887 (1917). Stafford Coal and Iron Co., and Richmond. Recovery of potassium salts from blast furnace flue dust or the like. (117,991.) Aug. 21.

16,013 (1917). Tschirner. Manufacture of potassium compounds from glauconite, etc. (117,870.) Aug. 14.

16,157 (1917). Scholes. Manufacture of potassium compounds. (117,755.) Aug. 8.

3528 (1918). Mineral Products Corporation. Purification of alumina. (118,063.) Aug. 21.

9672 (1918). Dehn (Henshaw). Obtaining alkaline earth fluorides and soluble potassium salts. (117,901.) Aug. 14.

VIII.—GLASS: CERAMICS.

APPLICATIONS.

Brooke and Twynam. Refraction bricks or blocks. 12,811. Aug. 7.

Dressler Tunnel Ovens, Ltd., and Rushton. Ovens. 12,896 and 12,897. Aug. 8.

Forster. Feeding molten glass from glass tanks or furnaces. 12,438. July 31.

Hailwood. Highly refractory compositions for use in building and repairing acid-lined metallurgical furnaces, etc. 12,744. Aug. 6.

Soc. Anon. des Prod. Refractaires de l'Ouest. Manufacture of silica bricks. 12,788. Aug. 6. (Fr., Aug. 6, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

13,780 (1917). Webb. *See* XI.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Carter, Ratcliffe, and Wright. Impregnation of porous or permeable substances with liquid or plastic materials. 12,457. July 31.

Jorgensen. Preventing or removing crust formation in rotary kilns. 12,986. Aug. 10. (Sweden, Feb. 28, 1917.)

Mulligan. Non-porous cement. 12,478. July 31.

Pedersen. Process for making wood lastingly soft and pliable. 13,022. Aug. 10.

Powell. Treatment of timber. 13,214. Aug. 14.

Hodgkinson. Production of azides. 12,881. Aug. 8.

Perruche, and Gros et Bouchardy. 12,454. *See* III.

COMPLETE SPECIFICATION ACCEPTED.

18,034 (1916). Creischere and Creischer. Machine for making pellets from pulverulent or granular explosive materials. (117,904.) Aug. 21.

XXIII.—ANALYSIS.

APPLICATIONS.

Aktiebolaget Ingeniörsfirma Egnell. Gas-analysing apparatus. 12,483 and 12,588. July 31 and Aug. 1. (Ger., July 31 and Aug. 1, 1917.)

Davis and Davis. Quantitative estimation of vapours in gases. 13,323. Aug. 16.

I.—GENERAL ; PLANT ; MACHINERY.

Evaporator for acid liquids. E. Hart, J. Ind. Eng. Chem., 1918, 10, 555.

Closed glass tubes, 4 ft. long and 3 in. diam., are arranged horizontally side by side on iron supports covered with asbestos; two or more series of these tubes are placed in steps one higher than the other, and each tube is provided with three 1 in. openings for the introduction of liquid and the escape of steam. The upper series of tubes discharge into the lower and the latter into a collecting channel for the concentrated liquid. The whole system is heated by the gases from a furnace, the liquid being warmed in the first set of tubes and then boiled and evaporated in the second set.

— W. P. S.

PATENTS.

Classifying granular materials; Process and apparatus for —. R. E. Trottier, Puteaux, France. Eng. Pat. 104,499, Jan. 3, 1917. (Appl. No. 148 of 1917.) Under Int. Conv., Feb. 29, 1916.

In the process claimed, separation is effected not only according to the "equivalence" (i.e., the density and volume) of the particles but also according to their shape. The materials to be separated are introduced into the upper part of the chamber, 6, which is fed with water through the pipe, 10. Any very light bodies remain in suspension and are carried away with the overflow water

through the conduit, 13. The remaining particles fall through the comparatively still water in the upper part of the vessel, 6, and slide down the inclined plates, 2, and 11. The rounded particles of the greatest "equivalence" are able to descend through the upward current of water and pass into the discharge, 7. The rounded particles of less "equivalence" are deviated to the discharge, 9, and the lightest ones to the outlet, 14. All flat particles slide down the plate, 11, and pass into the channel, 5, the inner wall, 4, of which is adjustable. They are turned edgewise by the ascending current of water and slide down the inclined wall, 3, into the discharge, 9.—W. H. C.

Sorting or separating solid substances; Apparatus for —. R. E. Trottier, Puteaux, France. Eng. Pat. 117,274, Dec. 22, 1916. (Appl. No. 18,409 of 1916.)

A SIEVE or equivalent device operating in air or any suitable liquid has a jerking motion imparted to it by being drawn backwards by the action of a cam and pulled suddenly forwards against a block by a spring.—W. H. C.

Separating dust from ores, coal and the like; Apparatus for —. R. Laudien, Ludwigsdorf, Prussia. Eng. Pat. 113,780, Dec. 22, 1917. (Appl. No. 19,005 of 1917.) Under Int. Conv., Feb. 26, 1917.

A CYLINDRICAL separating chamber is surrounded by a receiving chamber, both terminating at the lower end in conical receivers for the dust-free material and the dust respectively. Material to be treated is fed from a hopper on to a "thrower plate" in the inner chamber and meets a current of air produced by a fan situated in a flue connecting the inner and outer chambers. The sectional area at the "thrower plate" where the dust separation takes place, and also that of the return airway from the outer to the inner chamber, is made about equal to that of the fan channel.—C. A. K.

Volatilised solvents; Recovery by condensation of —. P. Persch, Cöln-Bransfeld, Germany. Eng. Pat. 116,590, July 28, 1917. (Appl. No. 10,865 of 1917.)

The mixture of volatilised solvent and air is sucked at a relatively low temperature by a fan into a heater, where it is heated to the boiling point of the solvent to be condensed. The mixture of vapour and air is immediately forced into a cooling chamber where the solvent is condensed and withdrawn through a separator to remove any water. The process is specially applicable to the manufacture of seamless rubber goods, and the whole apparatus may be enclosed and the air replaced by a non-oxidising gas such as nitrogen.—J. H. P.

Grinding mills, disintegrators, mixers, or the like. British Dyes, Ltd., J. Turner, and T. P. K. Crossland, Huddersfield. Eng. Pat. 116,958, Aug. 1, 1917. (Appl. No. 11,059 of 1917.)

A CLOSED, slightly conical, grinding cylinder with balls or rollers resting loosely on its bottom, and rotating on a horizontal axis, is provided with a controlled side outlet near the larger end. One end of a curved pipe is attached to the outlet, the other end terminating in a cone which is coaxial with the grinding cylinder and enters dust-tight into a closed receiver. The pipe is rotated with the cylinder. On opening the slide controlling the outlet, the ground material is discharged automatically through the curved pipe as the cylinder rotates, without emission of dust.—W. H. C.

Grinding or crushing machines. D. J. G. Miller, Bootle, and R. A. Lloyd, Liverpool. Eng. Pat. 117,281, May 26, 1917. (Appl. No. 7589 of 1917.)

A STATIONARY grinding ring forms the peripheral wall of a chamber the bottom of which consists of a revolving plate. Grinding rollers are supported above and revolve with the bottom plate; the rollers are mounted on arms which pass through the bottom plate and are pivoted below so that the rollers are free to move a limited distance towards and away from the grinding ring. Scrapers and brushes are provided to stir and lift the material.—W. H. C.

Shaft-furnaces; Method of and apparatus for charging —. P. Wüth, Luxembourg-Hollerich, Luxembourg. Eng. Pat. 117,024, Dec. 8, 1917. (Appl. No. 18,239 of 1917.)

To economise motive power in charging a shaft furnace, the cars for transporting the charging buckets horizontally are provided with automatic couplings, so that when a car from which a full bucket is suspended is coupled with a car carrying an empty bucket, the two hoisting shafts are also

coupled. The full bucket is then lifted and the empty bucket lowered so that the weights are partly counterbalanced. The cars are then uncoupled and the full bucket transported to the charging point and the empty bucket refilled.

—W. F. F.

Chemical reactions between gases and/or vapours; Method of and means for bringing about — by means of catalysts. C. S. Roy, and T. Morson and Son, Ltd., London. Eng. Pat. 117,103, June 2, 1917. (Appl. No. 7941 of 1917.)

Air or other gas is injected through a nozzle provided with a needle valve into the constricted neck of a mixing chamber. A second gas, or a liquid to be vaporised, fed through a sight tube in a valved pipe, is drawn into the mixing chamber by the injector action of the air jet. If the pressure rises above a predetermined amount, a spring-controlled piston is actuated and operates interconnected valves in the air and vapour supply pipes to control the flow. The mixture is passed, through a preheater if desired, to a casing containing the catalytic substance. The latter is arranged in horizontal tubes and is contained partly in shallow trays in each tube and partly resting in the tube itself. At the beginning of the reaction the catalyst is arranged in two portions, one at each end of the tube, and as the reaction proceeds, the two portions are brought together and then spread out by moving and jerking the trays, the latter being connected to a common rod operated from outside the casing. Excessive rise of temperature is thus prevented. If metallic gauze is used as a catalyst, a number of separate coils are inserted in each tube. The temperature of the catalyst may be varied and controlled by means of heating burners in the base of the casing, and by steam circulated through the casing. The gases pass from the reaction chamber through tubes containing spiral baffle-plates to a purifying tower through which liquid trickles down and thence to an absorbing chamber provided with inclined baffles over which the absorbing liquid flows.—W. F. F.

Air or gases; Centrifugal apparatus for the extraction and collection of dust from —. J. C. Wood, Garforth, Yorks. Eng. Pat. 117,173, Aug. 30, 1917. (Appl. No. 12,475 of 1917.)

Air containing dust is passed into the top of an inner concentric tube in a vertical cylindrical casing. The tube has longitudinal radial ribs extending inwards from the walls, and does not extend to the bottom of the casing, the air passing out under the lower end and upwards through the annular space, which is provided with radial partitions. The apparatus is rotated on its vertical axis, and the dust, which is separated centrifugally, falls to the bottom and is collected.—W. F. F.

Dust collector. U. Wedge, Ardmore, Pa., Assignor to The Process Engineering Co., Philadelphia. Pa. U.S. Pat. 1,267,023, May 21, 1918. Date of appl., Sept. 14, 1916.

A CHAMBER is provided with a series of superposed horizontal passages for the flow of the dust-laden gas and with a series of vertical passages through which the deposited dust falls. The vertical passages communicate with the horizontal passages only at the top.—W. H. C.

Separating matter from a fluid containing the same; Device for —. U. Wedge, Ardmore, Pa., Assignor to The Process Engineering Co., Philadelphia, Pa. U.S. Pat. 1,267,024, May 21, 1918. Date of appl., Oct. 26, 1916.

THE APPARATUS consists of a series of superposed tiers of inclined shelves between which the dust-

laden fluid is passed. The superposed tiers of shelves are arranged in pairs, the shelves of each pair being inclined in opposite directions towards a common vertical discharge shoot. The dust is deposited on the shelves, and slides by gravity towards the common shoot, into which it passes through constricted openings.—W. H. C.

Suspended solids in gases; Process of removing —. S. Peacock, Philadelphia, Pa., Assignor to Haslup and Peacock, Inc., New York. U.S. Pat. 1,268,486, June 4, 1918. Date of appl., Jan. 26, 1916.

THE GAS is treated with a spray of a liquid which will dissolve the solid matter. Any undissolved portions of the latter are circulated by, and subjected to a grinding action in, opposing streams of the solvent while fresh streams of gases are submitted to its action.—W. H. C.

Covering or jointing of pipes and the like; Material for the —. V. H. Majerius, Wyke, and J. M. Errington and A. Hammond, Bradford. Eng. Pat. 117,323, Aug. 2, 1917. (Appl. No. 11,110 of 1917.)

THE PACKING consists of a metallic soap used either alone or mixed with a suitable filling material such as asbestos, china clay, or the like. The metallic base of the soap is preferably chosen so that it forms an insoluble body with the acid or other corrosive material which the jointing has to resist.—W. H. C.

Drying liquid materials; Method of —. O. Carr, New York. Eng. Pat. 117,469, Apr. 13, 1917. (Appl. No. 5263 of 1917.)

IN A METHOD of drying liquid by spraying it into a large volume of heated air, the air passes through a drying chamber, a settling chamber, and a concentrating chamber in succession. The liquid is sprayed into the concentrating chamber and the concentrated liquid is collected and sprayed into the drying chamber, where the final evaporation takes place. The dried material separates from the air partly in the drying chamber and partly in the intermediate settling chamber and any particles still remaining in suspension are collected and retained by the liquid spray in the concentrating chamber.

Solidifying or concentrating liquid or semi-solid materials on a revolving cylinder; Apparatus for —. J. W. Leitch, Huddersfield. Eng. Pat. 117,560, Nov. 17, 1917. (Appl. No. 16,976 of 1917.)

A GROOVED roller revolves in the molten material, e.g., phenylenediamine, and feeds it on to a revolving drum through which a cooling medium passes. An adjustable scraper removes the solidified material and is situated above a receiving hopper at the bottom of which revolves a worm conveyor. The latter works in close fit within a tubular extension of the hopper, which passes out through the wall of the chamber enclosing the apparatus. The chamber may be evacuated if desired.—J. H. P.

Drying and the like; Apparatus for —. A. Tegoli, San Francisco, Cal. U.S. Pat. 1,268,797, June 4, 1918. Date of appl., June 20, 1916.

THE APPARATUS comprises a blower and a treating chamber provided with coils and connected by flow and return ducts with a series of drying chambers which are also connected together. The latter are provided with interchangeable drawers with apertures in the bottoms.—W. H. C.

Separation and settlement of solids and semi-solids from chemical and like manufacturing liquids. W. Clifford, Wolverhampton, and Jones and Attwood, Ltd., Amblescote, Staffs. Eng. Pat. 117,472, May 24, 1917. (Appl. No. 7467 of 1917.)

THE liquid is fed into a bucket in the centre of the settling tank at the top and overflows from the bucket into a relatively large body of liquid inside a guard chamber, open at the bottom, which is adapted to direct the relatively slow moving and large volume downwards in the centre of the body of liquid in the tank, thereby preventing disturbance of the settled solids at the bottom of the tank.

—J. H. P.

Settling tanks for clarifying liquids. Simon-Carves, Ltd., and S. Hunter, Manchester. Eng. Pat. 117,576, Jan. 30, 1918. (Appl. No. 1734 of 1918.)

A SETTLING tank is provided with a conical outlet on which are arranged three steam inlets. To remove sediment which has become more or less solid on prolonged stoppage and will not flow through the exit, steam is introduced through the steam inlets. A steam ejector or the like may also be provided to draw water from the upper part of the tank and force it into the sediment after it has passed the outlet valve.—J. H. P.

Settling tanks for clarifying liquids. Simon-Carves, Ltd., and S. Hunter, Manchester. Eng. Pat. 117,586, Mar. 21, 1918. (Appl. No. 4993 of 1918.) Addition to Eng. Pat. 117,576, Jan. 30, 1918 (see preceding abstract).

WATER under pressure is used instead of steam as described in the former patent.—J. H. P.

Spraying and atomising liquids; Apparatus for —. E. Slater, Greenfield, Yorks. Eng. Pat. 117,481, July 13, 1917. (Appl. No. 10,147 of 1917.)

IS an apparatus for forcing liquid to spraying nozzles, an ejector is connected with the liquid container and with the compressed air container. When the air pressure is normal the ejector is closed by a valve and compressed air passes to the liquid container and forces liquid to the spraying nozzles. If the air pressure falls, the valve is opened by a spring and the compressed air actuates the ejector, which draws in air from the space above the liquid in its container and thus stops the supply of liquid to the spraying nozzles.—J. H. P.

Steam-generator; Slag-heated —. U. Wedge, Ardmore, Pa., Assignor to Furnace Patent Co., Philadelphia, Pa. U.S. Pat. 1,267,022, May 21, 1918. Date of appl., July 16, 1914. Renewed Apr. 27, 1916.

MOLTEN slag is delivered into the upper part of a chamber partly filled with water and falls on to a baffle-plate whence it passes into the water in the form of spray and generates steam. The first chamber is connected with a second which has the form of a tubular heater or condenser. The steam and water spaces of the first chamber are connected with the steam and water spaces of one section of the heater, the other being supplied with water from a separate source.—W. H. C.

Mixing machine. W. F. Morse, Assignor to S. R. Parry, Rochester, N.Y. U.S. Pat. 1,267,578, May 28, 1918. Date of appl., Mar. 19, 1917.

A CONTAINER for the material to be mixed is clamped on to a turntable which rotates on antifriction

rollers mounted in pockets around the inside of the wall of a hollow base. Paddles carried by a rod supported in a bracket fixed to the base project into, and pass between, paddles fixed to the inner wall of the container.—J. H. P.

Agitator. Agitating means. N. D. Nielsen, Elyria, Ohio. U.S. Pats. (A) 1,268,601 and (B) 1,268,602, June 4, 1918. Dates of appl., Sept. 4, 1917, and Jan. 9, 1918.

(A) A TANK is constructed with its bottom dished inwards, and a horizontal shaft projects through the side wall and carries a propeller in the angle formed by the side walls and bottom. A stream of liquid is thus directed against the inclined bottom and then deflected against the opposite side walls which are inclined to one another in such a way that the liquid is divided into two streams moving in opposite directions back to the propeller. (B) In a modification of the apparatus described in (A), the bottom of the tank is dished outwards and the propeller is provided with substantially straight radial blades, so that the liquid streams are directed radially in a vertical plane. The liquid is deflected by the side walls and bottom on to the walls opposite the propeller, and then deflected back to the propeller.—W. F. F.

Refrigerating composition. F. G. Keyes, Boston, Mass. U.S. Pat. 1,267,772, May 28, 1918. Date of appl., Aug. 7, 1917.

THE volatile refrigerant, *e.g.*, ammonia, is absorbed in an aqueous solution that has a lower vapour pressure than water, *e.g.*, a mixture of 60% of ammonium nitrate, 25% of glycerin, and 15% of water.—W. H. C.

Separating liquids from solids; Process of and apparatus for —. A. M. Nicholas, Bismuth, N.S.W. U.S. Pats. 1,268,273 and 1,268,274, June 4, 1918. Date of appl., Nov. 24, 1916.

A SHALLOW cylinder open at one end is rotated about its horizontal axis. The interior of the cylinder is covered with filtering material on a suitable perforated support spaced away from the wall, and the space between the two is divided into separate compartments by partitions placed parallel to the axis of the cylinder. As the cylinder rotates these compartments are successively connected with a source of vacuum and with a supply of fluid under pressure. The mixture of liquid and solid is fed on the lowest part of the interior which is in communication with the vacuum and the liquid portion is sucked through. As the cylinder rotates the spaces come successively into the position opposite the supply of compressed air or other fluid, and the solids are blown off into a discharge shoot.

—W. H. C.

Aerating device. J. P. Ruth, jun., Denver, Colo. U.S. Pat. 1,268,630, June 4, 1918. Date of appl., May 31, 1917.

LIQUID to be aerated is contained in a tank provided with a central vertical pipe having an enlargement at the bottom with radial passages which communicate with the atmosphere through the central pipe. Another set of radial passages in the enlargement communicates with a short central depending pipe opening into the liquid near the bottom of the tank. The central pipe carries a pulley at the top, and when rotated liquid and air are circulated through the passages in the enlargement at the bottom.—W. F. F.

Still or retort. H. MacRae, Wilmington, N.C. U.S. Pat. 1,268,742, June 4, 1918. Date of appl., Mar. 28, 1918.

A VERTICAL cylindrical retort or still having a central tube is divided into compartments by horizontal partitions provided with openings and means for closing the same. The lowest compartment serves as a cooler for the residue from the upper compartments, which are each provided with a separate internal heating coil and with separate offtake pipes for the distillate.—W. H. C.

Treating certain mineral and chemical products: Apparatus for —. C. J. Leyes, Jersey City, N.J. U.S. Pat. 1,270,307, June 25, 1918. Date of appl., Feb. 20, 1917.

A SERIES of inclined conveyor tubes pass through a furnace chamber and are connected at their upper ends with a common feed hopper and at their lower ends with a common receiver. The tubes, hopper, and receiver are supported by a frame so that the whole can be tilted in a vertical plane independently of the furnace.—W. H. C.

Fire-extinguishing composition having a low freezing-point. G. E. Ferguson, New York, Assignor to Pyrene Manufacturing Co. U.S. Pats. (A) 1,270,392, (B) 1,270,394, (C) 1,270,395, (D) 1,270,396, and (E) 1,270,397, June 25, 1918. Dates of appl., (A) Aug. 12, (B) to (E) Oct. 20, 1914.

FIRE-EXTINGUISHING compositions of low freezing-point are composed of: (A) carbon tetrachloride, trichloromethane, and pentachloroethane; (B) a non-inflammable solvent and acetophenone dissolved therein, the solution having a freezing-point substantially lower than that of the solvent; (C) a stable fire-extinguishing solvent, *e.g.*, carbon tetrachloride, with oil of peppermint dissolved therein; (D) a non-inflammable solvent, *e.g.*, carbon tetrachloride with a camphor substitution product dissolved therein, the composition having a lower freezing-point than the fire-extinguishing component; (E) a carbon and chlorine compound, *e.g.*, carbon tetrachloride, with an organic acid, *e.g.*, propionic acid, dissolved therein.—A. de W.

Composition having a low freezing-point. G. E. Ferguson, New York, Assignor to Pyrene Manufacturing Co. U.S. Pat. 1,270,393, June 25, 1918. Date of appl., Oct. 20, 1914.

A SOLUTION comprising carbon tetrachloride and anisole dissolved therein.—A. de W.

Kneading and mixing of plastic substances: Jacketed troughs for machines for — and for like purposes. J. E. Pointon, and Perkins Engineers, Ltd., Peterborough. Eng. Pat. 117,005, Oct. 24, 1917. (Appl. No. 15,462 of 1917.)

Furnaces for heating air. J. Garner and R. H. Posnett, Runcorn. Eng. Pat. 117,165, Aug. 8, 1917. (Appl. No. 11,377 of 1917.)

Furnace. C. Zulver, London, Assignor to L. E. Smith, South Shields. U.S. Pats. 1,270,679 and 1,270,680, June 25, 1918. Date of appl., June 25, 1917.

SEE Eng. Pats. 106,704 and 106,703 of 1916; this J., 1917, 857.

Use of solid fuel for large scale power production. Eng. Pat. 117,920. See IIa.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Air from a mine fire; Analyses of —. A. G. Blakely and H. H. Geist. J. Ind. Eng. Chem., 1918, 10, 552–553.

FIRE broke out in an anthracite coal mine on November 18, 1916, and barriers were erected for the purpose of cutting off all supply of air and smothering the fire. Pipes were extended through the barriers and samples of the gases obtained at intervals from the fire zone. The quantity of oxygen present decreased gradually from 18.00% on December 1, 1916, to 4.80% on July 26, 1917; during this period the carbon dioxide increased, but not regularly, from 0.99 to 4.47%, whilst the methane increased from 2.40 to 10.9%. Carbon monoxide increased from 0.008% on December 1 to a maximum of 0.01% on December 26, then decreased to 0.001% on February 22, after which date none could be detected in the gases.—W. P. S.

Gas producers from which slag is tapped off: Comparison of — with those of the water seal type. H. Markgraf. Stahl u. Eisen, 1918, 38, 703–707.

Two producers working with liquid slag have given complete satisfaction for 4 years and another, capable of gasifying 100 tons per 24 hours, is now in course of erection. The producer is charged with dry coke of large size, together with open-hearth or other fusible slag, and blown with air only. A gas practically free from hydrogen is produced which, since it yields little or no moisture on combustion, is well suited to the heating of open-hearth furnaces. The sulphur in the gas varies from 0.126 to 0.468%, compared with a variation from 0.49 to 2.0% in gas from the Würth producer. The slag added with the charge readily dissolves the residue from the coke which is thus prevented from interfering with the continuous working of the producer. The addition of excess of a highly phosphoric slag to the coke charged into the producer yields a highly phosphoric pig iron of low melting point. The efficiency of this producer is 23% less than that of the Würth producer, since the slag additions have to be melted, but compensation for this is found in the fact that no heat is used up in the production of water-gas. The gas is very free from dust. Coke very high in ash, useless for the blast furnace, can be used in this producer, with or without slag additions. The life of the producer is from 9 months to a year. The gas produced contains 24.3% CO, and small quantities of hydrogen and methane, the residue being practically all nitrogen. The construction is similar to that of an ordinary producer, there being in addition slag holes below the air tuyères.—F. C. Th.

Ammonium sulphate; "Direct process" of making — in gasworks. 54th Annual Report on Alkali Works (Year 1917), by the Chief Inspector, 32–47.

ATTENTION in 1917 was mainly directed to the yield of ammonia from retorts under varying seasonal conditions, with a close watch on the loss of ammonia in the spent liquors from the still. Loss of ammonia at the bubbler has been observed, due to the removal of the tarry scum from the surface of the liquor in the effluent tank. Investigations on the poor yield by the "direct process" show that improvement must now be attained in the carbonising house, rather than in the bubbler, as the process is capable of effecting a recovery of approximately 95% of the ammonia leaving the retort. Chemical processes for the production of ammonia from hydrogen and nitrogen are making rapid progress, but the recovery of ammonia as a

by-product is capable of extended application, and important changes in gasworks practice are indicated. The use of steam in vertical retorts will materially increase the yield of ammonia and an increased use of an economical heat-giving gas is to be anticipated.—C. A. K.

Oil shales; Destructive distillation of — J. C. Morrell and G. Egloff. Chem. and Met. Eng., 1918, 19, 90—96.

EXPERIMENTAL distillation of an oil shale from the Green River formation gave as products per ton of shale: oil, 20.3 galls.; permanent gases, 19.47 cub. ft.; ammonium sulphate, 25.4 lb. Evolution of ammonia was first noted at 365° C., and increased at an unrecorded temperature above 400° C. The distillate was collected in 100 c.c. fractions; the sp. gr. of the oil portion in the first fraction was higher than in the second or third, with subsequent increase again in later fractions. The ammonia content of the aqueous distillate increased to a maximum. Benzene, toluene, and xylene were present in small amounts in the oil distillate, but difficulty in working up the oil into a motor fuel will be experienced owing to the presence of sulphur, nitrogen, unsaturated hydrocarbons of the terpene type, and phenolic compounds. The higher boiling fractions are lubricating oils of similar properties to those obtained from California and Russian petroleum, and are probably highly naphthenic in character. A shale oil industry will require high technical skill and large capital and competition with petroleum wells in the near future is questionable.—C. A. K.

Lubricating oils; Dubrisay's method of testing [viscosity of] — P. Nicolardot and P. J. Masson. Ann. Falsif., 1918, 11, 77—79.

THE authors consider that the results given by the Dubrisay viscometer (this J., 1917, 1123) are materially affected by the density and surface tension of the oils tested, and that at temperatures other than atmospheric the thermal conditions are unsatisfactory. Tests made on different oils at various temperatures show that while a constant relationship exists between the results given by the Ostwald viscometer and the Barbey ixomètre, the relationship between the results given by the Barbey and the Dubrisay instruments varies with different oils.—T. St.

Analysis of ammoniacal liquors. See VII.

Manufacture of amyl acetate and similar solvents from petroleum pentane. Brooks and others. See XX.

PATENTS.

Coal-washing apparatus. L. Llewellyn, Assignor to Pittsburgh Coal Washer Co., Pittsburgh, Pa. U.S. Pat. 1,267,565, May 28, 1918. Date of appl., Jan. 5, 1918.

A WASHING tank is provided with a vertical transverse screen terminating below the top, and the coal is received on a perforated platform at one side of the screen and slightly inclined downwards towards its upper end. A similar delivery platform oppositely inclined is provided on the other side of the screen. A horizontal reciprocating shaft extends transversely through the tank below the platforms and carries three plungers of different sizes, one in each compartment below the platforms, and one moving centrally through the screen. A circulation of liquid through the perforated platforms is thus obtained. The receiving platform ter-

minates short of the central screen and the washed out material is discharged into the tank through the space between them. This space may be closed by a gate.—W. F. F.

Alcohol; Solid — and process of producing same. A. Strobl, Assignor to S. Sternau and Co., New York. U.S. Pat. 1,266,080, May 14, 1918. Date of appl., Feb. 11, 1915.

CLAIM is made to products consisting of alcohol, metallic soaps, and free fatty acid, and in particular to products containing alcohol, sodium stearate, and stearic acid. For example, alcohol at 140°—160° F. (60°—71° C.) may be treated with 2—3% of stearic acid and the latter subsequently nearly neutralised by addition of sodium hydroxide.

—J. U. L.

Solid fuel; Process of burning — O. B. Evans, Lansdowne, Pa., Assignor to The United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,267,646, May 28, 1918. Date of appl., Jan. 3, 1916.

THE fuel is fed into the top of a vertical cylindrical furnace which is constricted near the bottom. The air blast is regulated so that the ash is fused above the constriction and a combustible mixture of clinker and carbon passes downwards. Below the constriction an annular space is left between the wall of the furnace and the mixture of clinker and carbon moving downwards, and air for burning out the carbon from the clinker is injected into this space.—W. F. F.

Coke-oven. F. Peiter, Cleveland, Ohio. U.S. Pat. 1,267,332, May 21, 1918. Date of appl., Sept. 11, 1916.

THE combustion flues of a coke oven are arranged in groups of four, and in series in each group. Air for combustion is preheated by passing through a regenerator, and delivered to the top of the first flue of each group. Combustible gas is supplied to the top of the first and third flues, baffles are arranged in the second and third flues, and the hot gases from the fourth flue are led to the regenerator.—W. F. F.

Power production; Use of solid fuel for large scale — Merz and McLellan, and A. C. Michie, Newcastle-on-Tyne, and E. G. Weeks, Monk-seaton. Eng. Pat. 117,290, July 6, 1917. (Appl. No. 9817 of 1917.)

Coal is fed continuously into a retort, A, and the coke residue continuously discharged on to the grate, B¹, of a boiler, B. High-pressure steam from the boiler passes through a high-pressure superheater,

B², to a turbine, C, from which partially expanded "bleed" steam is taken at the point, C¹, and fed through a low-pressure superheater, D, combined with the superheater, B², in the boiler furnace, to

the retort, A, for the low temperature distillation of the coal. The exhaust steam from the turbine passes to a condenser, F, and the condensed water is pumped from the well, F¹, through the retort gas condenser, G, to cool the latter, and then through the usual feed-water heaters back to the boiler, B. The retort gases pass by the pipe, J, through the water-cooled condenser, G, and pipe, K¹, to a cooler, K, and then to a stripping plant, L, to recover light oils and other by-products. The gas may then be used for any power purposes, e.g., for heating the boiler, B, as shown, or in other steam generators or internal combustion engines.

—W. F. F.

Gas producers; Vaporising apparatus of —. Le Gaz Pauvre Economique, Nantes, France. Eng. Pat. 112,282, Dec. 28, 1917. (Appl. No. 19,166 of 1917.) Under Int. Conv., July 19, 1915.

THE base, 5, of the producer is surrounded by an annular water vessel, 3, formed by two members, 1, 2, the member, 1, having a conical seating on the

member, 2. The water is evaporated at a rate corresponding to the temperature of the fire, and the steam is superheated and the fire temperature lowered by passing the steam through the annular space, 4, to the producer.—W. F. F.

Coal gas; Manufacture and treatment of —. G. Helps, Nuneaton. Eng. Pat. 117,308. (Appl. Nos. 10,224, July 14, and 12,043, Aug. 22, 1917.)

ALL the gas retorts in a bed are charged simultaneously, and maintained at a pressure above the external pressure in the furnace to prevent admission of inert gases. The gases from several retort beds are led to a common receiver at a temperature sufficiently low to prevent interaction between them. The discharge main from the receiver is provided with one or more nozzles facing upstream, through which air, producer-gas, or water-gas is injected to dilute the coal gas to any desired calorific value.—W. F. F.

Gas generators or the like; Apparatus for feeding fuel to —. G. H. Bentley and E. G. Appleby, London. Eng. Pat. 117,348, Sept. 20, 1917. (Appl. No. 13,553 of 1917.)

A ROTARY feeding drum above the generator is operated by a reciprocating rod through a pawl and ratchet wheel, and the fuel falls on to an adjustable distributing cone in the mouth of the retort. By means of an additional ratchet wheel and reverse pawl, and cams, the direction of rotation of the feeding drum is reversed at intervals in order to maintain a level surface of the fuel in the generator. To facilitate access to the distributing cone this is suspended from a balanced lever pivoted on a detachable frame secured to a frame supporting the feeding drum.—W. F. F.

Gas-producer. J. W. Hornsey, Summit, N.J., Assignor to General Reduction Gas and By-Products Co. U.S. Pat. 1,267,410, May 28, 1918. Date of appl., July 3, 1914. Renewed Aug. 17, 1917.

FOR the continuous manufacture of producer gas, a horizontal rotating cylinder with a refractory lining is provided internally with sets of lifting blades or pockets, each set being out of alignment with adjacent sets. The material is admitted at one end of the cylinder and its longitudinal movement is obstructed by circumferential rings at intervals. A gas outlet is provided at the charging end of the cylinder, for gas and gaseous by-products, and an outlet at the other end for gas free from tar. Means are provided for directing the flow of gas towards either outlet as desired.

—W. F. F.

Gas; Manufacture of —. J. M. Rusby and O. B. Evans, Assignors to The United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,268,628, June 4, 1918. Date of appl., Oct. 11, 1913.

THE charge of coal or the like in a vertical retort is divided horizontally by layers of porous refractory material, and the gas is delivered through a central perforated vertical pipe. The gas is distilled at a pressure sufficient to force it through the refractory layers and also through the coal layers from the hot circumference to the cooler centre.

—W. F. F.

Natural-gas substitute [water-gas]; Process of and apparatus for making —. C. S. Palmer, Pittsburgh, Pa. U.S. Pat. 1,268,763, June 4, 1918. Date of appl., Oct. 5, 1917.

FUEL is charged into a retort formed of a metal in the same periodic group as iron but having a greater atomic weight and not readily oxidised, the thickness of the walls being not greater than 1.5 in. The retort is relatively narrow and is strongly heated externally without an internal air blast. Steam is injected to produce water-gas.

—W. F. F.

Desulphurisation of gases and other fluids containing sulphuretted hydrogen. H. W. Hemingway, London. Eng. Pat. 117,387, Nov. 21, 1917. (Appl. No. 17,165 of 1917.)

IN the process for desulphurising coal and other gases, or ammoniacal sulphide liquors, with ferrous carbonate, which is described in Eng. Pat. 12,093 of 1901 (this J., 1902, 906), the ferrous carbonate is recovered for use. Coal gas is passed through scrubbers and the ammoniacal liquor then treated with ferrous carbonate. The liquor is run off to a still or returned to the scrubbers, and the precipitated ferrous sulphide is converted into sulphate by any known method. The ammoniacal liquor is added to the ferrous sulphate and the precipitate converted into ferrous carbonate by absorption of carbon dioxide. The ammoniacal liquor is transferred to a still and the cycle may then be repeated.

—W. F. F.

Gas-washer. H. A. Dreffeln, Chicago, Ill. U.S. Pat. 1,268,100, June 4, 1918. Date of appl., May 3, 1913.

TWO concentric pipes, tapering slightly towards the bottom, are mounted one within the other on a vertical axis. The two surfaces bounding the annular space are constructed with complementary helical corrugations and the distance between them may be varied by moving the inner pipe vertically by a screwed vertical rod. The outer pipe is

mounted in a casing, and gas admitted to the upper part of the casing must pass downwards through the tortuous passage between the pipes. Means are provided to supply jets of water or steam to the corrugated surfaces.—W. F. F.

Gas process. F. P. Peterson, Tulsa, Okla., Assignor to Consolidated Liquid Gas Co., Chicago, Ill. U.S. Pat. 1,266,621, May 21, 1918. Date of appl., Jan. 5, 1914. Renewed Jan. 26, 1918.

CRUDE natural gas is compressed and then passed through a cooler. The condensed liquid is passed back through the cooler and the most volatile constituents removed by allowing them to vaporise and expand at a lower pressure, whereby the gas and liquid are cooled. The process may be used to separate several liquefiable constituents by liquefying them in the inverse order of their volatility and treating each condensed fraction as above. The volatile portions removed are returned to the unliquefied gas for further treatment.

—W. F. F.

Hydrocarbons; Treatment of liquid — for the transformation thereof. C. E. and N. C. Cassal, and B. H. Gerrans, London. Eng. Pat. 117,087, June 29, 1916. (Appl. No. 9178 of 1916.)

A LIQUID hydrocarbon, such as petroleum oil, is passed through a horizontal tube filled with fragments of graphite or alumina and heated to 700° C. The resulting product contains benzene and toluene.

—W. F. F.

Crude oil; Process of and apparatus for preparing — for distillation. J. O. Jensen, New York. U.S. Pat. 1,268,721, June 4, 1918. Date of appl., Feb. 24, 1917.

A CURRENT of crude oil is heated to above 400° F. (above 200° C.) and the water and low-boiling fractions are removed. The oil then passes into a tank in which it is cooled, by means of cold oil circulating through a number of ducts within the tank, to a temperature above the boiling point of water but below the flashing point of the oil. From the tank the oil is conveyed into the still.

—L. A. C.

Coke, coal, and other material; Machines for cutting, crushing, or breaking —. A. G. Sims, Reading. Eng. Pat. 117,585, Mar. 11, 1918. (Appl. No. 4266 of 1918.)

Gas generators or the like; Automatic removal of ashes from —. G. H. Bentley and E. G. Appleby, London. Eng. Pat. 117,534, Sept. 20, 1917. (Appl. No. 13,554 of 1917.)

Gasifying liquid hydrocarbons; Apparatus for —. A. W. Southey, London. Eng. Pat. 116,970, Aug. 23, 1917. (Appl. No. 12,108 of 1917.)

Fuel blocks or briquettes; Manufacture of —. E. R. Sutcliffe, Leigh. Assignor to Pure Coal Briquettes, Ltd., Cardiff. U.S. Pat. 1,267,711, May 28, 1918. Date of appl., Mar. 27, 1915.

III.—TAR AND TAR PRODUCTS.

Viscous tar, etc.; Determining specific gravity of — at different temperatures. A. R. Myhill. Gas J., 1918, 143, 254.

A THIN glass tube about 2 ft. in length and $\frac{3}{8}$ in. internal diameter, sealed at one end, is weighed with a thermometer inside and after removing the thermometer, placed in a vertical position in a glass water-jacket of about 2 in. diameter and 2 ft. in height, containing water at or near the boiling point. A small portion of the tar, previously heated to about 100° C. by immersing the vessel containing it in boiling water, is then poured into the tube, any adhering to the sides being removed. The level of the tar is marked with a file and its temperature taken. The tube is again weighed with the thermometer inside, and the weight of the tar determined. The volume of the tar is then obtained by cleaning out

the tube and running in water from a burette, the water as it is run in being warmed up to the temperature of the tar at the time of making the file mark, by again immersing the tube in the water-jacket. By repeating the readings at two or three different temperatures, say 20° to 30° apart, a curve can be constructed for converting the volume of the tar at any temperature to that at a standard temperature.—L. A. C.

Analysis of ammoniacal liquors. See VII.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Dyestuffs; Manufacture of — and processes of dyeing therewith. N. Malcolmson and F. W. V. Fitzgerald, London. Eng. Pat. 117,095, Apr. 4, 1917. (Appl. No. 4856 of 1917.)

WOOLLEN yarn or fabric is dyed brown to black by the use of a soluble or insoluble lead compound, such as litharge, in conjunction with a mordant composed of sodium or calcium hydroxide, or mixed with sodium carbonate and calcium oxide. When calcium hydroxide is used, a small quantity of ammonium chloride is added to prevent the formation of insoluble calcium carbonate, and sodium chloride may be added to retard the formation of the colour. A soluble lead salt may be combined with nitrate, sulphate, or other salt of copper or iron, by first rendering the copper or iron salt anhydrous, and then replacing the water of crystallisation by a saturated solution of the lead salt, this being used in conjunction with a mechanical mixture of sodium carbonate and calcium oxide. The mixture containing copper produces a khaki and that containing iron a brown shade on wool. Sulphur may be added to the foregoing mixtures, either mechanically or by dissolving the sulphur in heated paraffin, and adding the lead, copper, or iron salt to the dissolved sulphur, the dyestuff being then suitable for dyeing cotton yarn or fabric a deep greyish black.—B. N.

Anthracene [vat] dyes and process of making them. H. Wolff and F. Kacer, Mannheim, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,266,896, May 21, 1918. Date of appl., Dec. 1, 1913.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Lignin; Researches on —. I. Lignosulphonic acids. M. Hönig and J. Spitzer. Monatsh. Chem., 1918, 39, 1—14.

By the careful evaporation of sulphite-cellulose waste liquor it is possible to obtain a solution of "lignosulphonic acid" which by conversion into the calcium or barium salt and subsequent fractional precipitation from the aqueous solution by alcohol, can be separated into several fractions of different composition. The barium salt obtained in this way can be separated into fractions of the composition $C_{13}H_{10}O_{18}S_2Ba$, containing four methoxyl groups, $C_{10}H_{14}O_{16}S_2Ba$, containing one methoxyl group, and $C_{14}H_{16}O_{18}S_2Ba$, containing three methoxyl groups, the last formula referring to the portion which remains unprecipitated. The salts thus obtained are amorphous brown solids whilst the corresponding free acids are soluble in water, ethyl alcohol, or acetic acid and liberate carbon dioxide from carbonates.—D. F. T.

PATENTS.

Paper; Apparatus for colouring —. J. Galloway and A. Stratton, Portobello, Scotland. Eng. Pat. 117,428, Apr. 8, 1918. (Appl. No. 5958 of 1918.)

AN overhead tank containing dye liquor is provided with a pipe delivering the dye through a horizontal, perforated, spray pipe, arranged parallel to a calender roll, on to the outer surface of the paper on the roll. A "doctor" or distributing box, having a felt strip engaging the paper, collects the surplus dye, and the latter is passed to a receiver from which it is pumped to the overhead tank.—B. N.

Porous fabrics [paper-board]; Saturation of — [with asphalt]. E. J. Cady, Chicago, Ill. U.S. Pat. 1,268,430, June 4, 1918. Date of appl., Apr. 2, 1917.

ONE surface of a travelling length of paper-board is subjected to the weight of a body of asphalt solution, while the opposite surface is maintained under reduced air pressure and out of contact with the solution.—W. E. F. P.

Cellulose film; Composite —. J. E. Brandenberger, Thion-les-Vosges, Assignor to Soc. La Cellophane, Paris. U.S. Pat. 1,266,766, May 21, 1918. Date of appl., May 26, 1914.

SEE Fr. Pat. 458,638 of 1913; this J., 1913, 1063. The outer films may be of nitrocellulose, and small particles of solid material may be incorporated with the plastic material in the intermediate layer.

Paper machines; Fourdrinier —. A. J. Davies, Kenogami, Quebec. Eng. Pat. 107,579, May 25, 1917. (Appl. No. 7569 of 1917.)

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Thiosulphuric, sulphurous, trithionic, and sulphuric acids; Estimation of mixtures of — O. Billetter and B. Wavre. Helvetica Chim. Acta, 1918, 1, 174—180.

THE solution containing the acids is warmed with bromine water, whereby the acids are converted entirely into sulphuric acid, which is estimated as barium sulphate. The sum of the sulphite and thiosulphate is determined by titration with standard iodine solution. If no trithionate is present the sulphite may then be estimated by titration with standard sodium disulphide, when the change

$\text{Na}_2\text{S}_3 + \text{Na}_2\text{SO}_3 = \text{Na}_2\text{S} + \text{Na}_2\text{S}_2\text{O}_3$ takes place. This estimation is carried out in the presence of ammonium chloride at the boiling point, the end of the reaction being indicated by the persistence of the yellow colour of the standard solution. If trithionate is present alone, the reaction is $\text{Na}_2\text{S} + \text{Na}_2\text{S}_3\text{O}_6 = 2\text{Na}_2\text{S}_2\text{O}_3$; the estimation is carried out by adding sodium sulphide to the solution and boiling for a few minutes, an excess of sodium acetate and some acetic acid is then added and the solution again boiled to decompose the excess sulphide; after cooling, the thiosulphate produced is titrated with standard iodine. Should both sulphite and trithionate be present, the sodium disulphide titration is carried out as described above, the end point being indicated both by the yellow colour and the formation of a turbidity due to sulphur, and then the trithionate titration proceeded with as above described. The method gives good results.—J. F. S.

Hydrocyanic acid; Decomposition of solutions of — W. Lewcock. Pharm. J., 1918, 101, 50—51.

ADDITION of sodium carbonate to a 30% solution of sodium cyanide causes, in time, the formation of a brown deposit, whereas caustic soda has not the same action. The brown decomposition product appears to be formed by the action of the alkali on free hydrocyanic acid produced by the hydrolysis of the cyanide, whilst the presence of caustic soda suppresses the hydrolysis. The decomposition of dilute solutions of hydrocyanic acid on storage may be attributed to the action of small quantities of basic substances principally derived from the glass vessels, possibly also from the use of hard water in the preparation of the solutions. Addition of bases or salts with alkaline reaction greatly accelerated the decomposition of hydrocyanic acid solutions. Substances such as alcohol, glycerin, and mannitol did not prevent the rapid decomposition of the hydrocyanic acid, but sulphuric acid, tartaric acid, and even carbon dioxide had a protective action depending on the concentration. An 8% solution of hydrocyanic acid in distilled water showed a yellow coloration in 2 days but in presence of 1% of sulphuric acid, calculated on the weight of hydrocyanic acid, the solution remained colourless for 23 days. It is calculated that the addition of 10% of sulphuric acid on the weight of hydrocyanic acid would preserve the solution indefinitely. (See also J. Chem. Soc., 1918, i., 382.)—J. F. B.

Acetic acid; Determination of — by distillation with phosphoric acid. W. F. Munn. J. Ind. Eng. Chem., 1918, 10, 550—552.

FIVE grms. of the sample is placed in a round-bottomed flask attached to a condenser by means of a three-bulb still-head which is made in one piece with the condenser tube. The receiver consists of a conical suction flask containing a known excess of standardised barium hydroxide solution. Dilute phosphoric acid solution (40 c.c. of 85% phosphoric acid solution and 20 c.c. of water) is added to the sample in the distillation flask, a gentle current of air is drawn through the apparatus, the inlet tube for the air being provided with a soda-lime tube, and the contents of the flask are boiled. Dilute phosphoric acid is then admitted to the flask through a tapped funnel at the same rate at which the liquid distils. At the end of the distillation, which usually requires about 90 mins., the contents of the receiver are titrated with N/10 hydrochloric acid, using phenolphthalein as indicator. N/1 hydrochloric acid is then added to dissolve any barium carbonate present, and the excess of acid is titrated

with $N/1$ sodium hydroxide solution using methyl orange as an external indicator. The latter titration gives the correction to be applied for carbonate. —W. P. S.

Nitric oxide and oxygen; Velocity of reaction between —. M. Bodenstein. Deuts. Bunsen-Ges., Apr., 1918. Z. Elektrochem., 1918, 24, 183—201.

OVER the temperature range 0° — 90° C. the reaction between nitric oxide and oxygen proceeds according to the equation: $dx/dt = kC_{O_2}C_{NO}$, that is the reaction is of the third order. The velocity falls with increase in temperature and is not affected by the presence of nitrogen peroxide or water vapour. Sulphur dioxide is also without influence on the reaction, and hence, conversely, the oxidation of sulphur dioxide cannot be catalysed by oxides of nitrogen, and in the sulphuric acid chamber nitrogen peroxide acts not in the gas phase but only after condensation to $HSNO_2$. The controversy between Lunge and Raschig (this J., 1904, 934, 1213; 1905, 131, 923; 1906, 533; 1907, 965) is considered and Lunge's view of the mechanism of the oxidation of nitric oxide is confirmed. Raschig's experimental methods are shown to be faulty for mixtures in which less than 50% of the nitric oxide has been converted into nitrogen peroxide. In the case of such mixtures the nitrogen peroxide and an equivalent quantity of nitric oxide would dissolve as N_2O_3 in the absorption medium, the equilibrium $NO + NO_2 \rightleftharpoons N_2O_3$ being attained practically instantaneously, and any remaining nitric oxide would be evolved. Hence in such circumstances the fact that the N : O ratio in the products absorbed is 1 : 1, as found by Raschig, affords no support for his view that nitric oxide is oxidised rapidly to N_2O_3 , and the latter then slowly oxidised to NO_2 . (See also J. Chem. Soc., Sept., 1918.)—J. F. S.

Nitric oxide; Velocity of oxidation of —. E. Briner and E. Fridöri. Helvetica Chim. Acta, 1918, 1, 181—185.

THE velocity of oxidation of nitric oxide in mixtures of air and nitric oxide such as are obtained in the manufacture of nitric acid from the atmosphere, takes place with a measurable velocity and conforms to the equation for a reaction of the third order. Lowering of the temperature by 10° over the interval 0° — 60° C. increases the velocity by 10—20%.—J. F. S.

Gas; Ionisation of — during chemical reaction. [Interaction of nitric oxide with oxygen and with chlorine.] A. Pinkus. Helvetica Chim. Acta, 1918, 1, 141—145.

THERE is no ionisation of the reacting gases when oxygen and nitric oxide are allowed to react under a pressure of $\frac{1}{4}$ — $\frac{1}{2}$ atm., nor is there any ionisation when chlorine reacts with nitric oxide, provided that the chlorine is not in excess. If, however, the chlorine is in excess, there is a marked ionisation. (See also J. Chem. Soc., Sept., 1918.)—J. F. S.

Ammonia and hydrochloric acid; Estimation of — by weighing as ammonium chloride. A. Villiers. Bull. Soc. Chim., 1918, 23, 306—308.

THE author reaffirms the accuracy of his method (compare Bull. Soc. Chim., 1900, 23, 253) for the estimation of ammonia or hydrochloric acid by weighing as ammonium chloride. Ammonium chloride did not lose weight when heated for 3 days and 3 nights at 105° C.; the small, gradually diminishing losses which have been observed by other workers were probably due to the slow elimination of the last traces of moisture.—W. G.

Ammoniacal liquors; Analysis of —. 54th Annual Report on Alkali Works (Year 1917), by the Chief Inspector, 22—31.

THE difficulty in the complete analysis of ammoniacal liquors is again noted and revision of certain methods (this J., 1910, 943) is necessary. In the estimation of thiocyanate the use of lead carbonate to remove sulphide leads to unreliable results unless precautions are taken to exclude air during the operation, and lead carbonate is regarded as an unsuitable agent, particularly if cyanides be present. Boiling is preferred with minimum exposure of the solution to air. 60—70 c.c. of distilled water is boiled to expel dissolved oxygen and 50 c.c. of liquor run into the boiling water, the boiling being continued to expel ammonium cyanide and sulphide. 10 c.c. of a saturated solution of ammonium iron alum is added, and the solution separated by decantation and filtration. Cuprous thiocyanate is then precipitated by adding sodium bisulphite and an excess of copper sulphate solution, and after standing for 30 mins. the solution is filtered and the precipitate washed, digested with 25 c.c. of a 4% solution of sodium hydroxide at 30° — 40° C., acidified with nitric acid, and titrated with $N/10$ silver nitrate solution, using a solution of iron alum as indicator. A sharper end-point is obtained by adding an excess of silver nitrate and titrating back with ammonium thiocyanate. Cyanide in liquors of high strength is most conveniently determined by the "polysulphide" method, in which cyanide is converted into thiocyanate by the action of ammonium polysulphide and titrated with silver nitrate. The pre-existing thiocyanate and chloride in the liquor are determined by a blank experiment. Attempts to estimate polysulphide in liquors by a simple method have only met with partial success. The liquor is mixed with an excess of ammonium cyanide solution of known strength in a stoppered vessel and the thiocyanate formed is determined. An alternative method is to determine the excess of cyanide by distillation. Both these methods are, however, subject to interference from dissolved oxygen.—C. A. K.

Bicarbonates and carbonates, or alkali carbonates and hydroxides; Method of analysing mixtures of —. J. Clarens. Ann. Chim. Analyt., 1918, 23, 148—152.

THE method depends on the determination of the quantity of carbon dioxide liberated when the carbonate mixture is titrated, the operation being carried out in a flask provided with a mercury manometer.—W. P. S.

Lime and magnesia; Latent heats of fusion of —. E. W. Washburn. Trans. Amer. Ceram. Soc., 1917, 19, 195—200.

THE author has calculated the latent heat of fusion of lime and magnesia from the freezing point-solubility formula for solutions. The value for lime is 28,000 ($\pm 20\%$) calories per grm.-mol. or 490 calories per grm., and that of magnesia 28,000 ($\pm 15\%$) calories per grm.-mol. or 700 calories per grm. Similar values were obtained for various silicate minerals. Hence, the low fusibility of these materials is due, in considerable degree, to their latent heat of fusion.—A. B. S.

Alumina; Preparation of — in the aluminium industry with special reference to rotary kilns. W. von Escher. Chem.-Zeit., 1918, 42, 353—355.

GREAT difficulty is experienced in obtaining calcined alumina suitable for the production of aluminium and free from such impurities as iron, silica, and titanium oxide. Most of the methods used for purifying the alumina are based

on the solution of the aluminium as aluminate, the other constituents of the ore remaining undissolved. The ore is washed to remove sand, crushed to the size of hazel nuts, and calcined at 450°C . Calcining at a much higher temperature reduces the yield of alumina and makes the subsequent grinding more difficult. A rotary kiln is used, connected with a rotary cooler. The calcined material is ground until a sample leaves only 15% residue on a 180-mesh sieve; the finer the material the greater is the yield of alumina. The ground material is stored in bins, at least a week's supply being kept in stock. It may be treated by any of the five following methods. *Bayer's wet process* (Ger. Pats. 43,977 and 65,604; see also this J., 1888, 625, 748; 1893, 263, 353, 925). The ground calcined material is thoroughly mixed with 40–45% soda-lye in the proportion of 1 mol. Al_2O_3 to 1.8 mols. Na_2O . The formation of sodium aluminosilicates is prevented by the addition of quicklime to the crude ore before grinding it. The mixture of calcined ore and lye is heated under pressure for 5 hrs. in a wrought iron autoclave fitted with a mechanical stirrer to convert the alumina into soluble sodium aluminate, a yield of 80% being obtained. The "red lye" thus produced is run into large tanks fitted with stirring mechanism and means for indirect heating, in which it is diluted with wash-water to 25°B . (sp. gr. 1.21). It is then filtered and the residue washed until free from alkali. The use of great pressure in the filter-presses causes the finer particles to pass through. The solution which runs from the filters is re-filtered in separate filters. The residue may be used for purifying coal-gas or as iron-ore. The filtrate—which contains 90–160 grms. Al_2O_3 and 100–110 grms. Na_2O per litre—is pumped into tanks 20–30 ft. high and 10–20 ft. diameter in which it is subjected to constant agitation for 5–7 days to precipitate aluminium hydroxide; the addition of aluminium hydroxide facilitates the precipitation. The well-stirred liquid should contain up to 6 mols. Na_2O to each 1 mol. Al_2O_3 , i.e. about 30 grms. Al_2O_3 remains in each litre of solution. The aluminium hydroxide is filter-pressed, the filtrate evaporated to one-third of its volume and used for treating further quantities of material in the autoclave. The wash-water, of sp. gr. exceeding 1.075 (10°B), is also evaporated, but that of lower density is used for diluting the "red lye." The press-cakes, which consist of friable granular aluminium hydroxide showing a loss on ignition of 45–50%, are afterwards calcined. *Dry process (treatment with soda)* (Ger. Pats. 93, 1650, 19,784, 25,777, and 70,175). This process is not suitable for silicious bauxites unless they have previously been washed. A high iron-content is less injurious than in Bayer's process. The ground, calcined bauxite is mixed with sodium carbonate (1.2–1.5 mols. Na_2O for each 1 mol. Al_2O_3) and a little coal and is then passed through a damping mixer into a rotary kiln in which it is heated until the mass slinters, and all the carbon dioxide has been expelled. The sintered mass is extracted as rapidly as possible with water above 80°C ., about 2.5 cub. m. of liquid being used for each 1000 kilos. of product. Caustic soda is added to bring the Al_2O_3 : Na_2O ratio to 1:1.8; if the extraction is unduly prolonged aluminium hydroxide will be precipitated and lost. The product is filtered, and the filtrate (sp. gr. 1.26–1.32, 30° – 35°B), at a temperature of 80°C ., is run into tall cylindrical "carbonators" in which the aluminium hydroxide is precipitated by carbon dioxide. The wash-water is used for extracting a further quantity of slintered material. In order to obtain the aluminium hydroxide in a granular form, attention must be paid to the concentration of the solutions. The aluminium hydroxide is calcined. The filtrate and wash-water are evaporated *in vacuo* in order to recover the sodium carbonate. *Peniakoff's pro-*

cess (Ger. Pats. 80,063, 93,952, and 247,762; see also this J., 1891, 947; 1896, 808; 1910, 1451). The ground, calcined bauxite is mixed with sodium sulphate and coal, moistened, and heated in a rotary kiln to 1400°C . or until the mass slinters. Sulphur dioxide and carbon dioxide are expelled. The proportions of the various ingredients have an important influence on the yield. The formation of sulphides is prevented by passing a current of air through the kiln. The sintered mass is treated as in the soda process; the gases from the kiln are treated by Hargreaves' process in order to convert the sulphur dioxide into sodium sulphate. *Process of Chem. Fabr. Griesheim-Elektron* (Ger. Pat. 232,563; this J., 1911, 621). The clay or bauxite is boiled with sulphuric acid and the solution is allowed to crystallise. Aluminium sulphate separates out, whilst iron sulphate remains in solution. Any traces of iron in the crystals may be separated by dissolving them in hot sulphuric acid and recrystallising. *Serpck's process* (Patents owned by Soc. Gén. des Nitrures; see this J., 1906–1917). A mixture of bauxite and coal is heated in a current of producer gas in a rotary kiln, with an electrically heated zone, to between 1400° and 1850°C . until the alkalis, alkaline-earths, and silica compounds are volatilised and aluminium nitride is formed. On treating the nitride with water, ammonia is formed and recovered as sulphate and this important by-product reduces the cost of the alumina. This process was not used commercially before the war and little is known about it. In comparing the foregoing processes, attention must be paid to the composition of the raw bauxite. A material rich in iron but low in silica is preferably treated by a dry process, but silicious bauxites should be purified by Bayer's process. Very hard bauxites, such as those in Hungary, are best treated by heating with soda to a slintering temperature. The relative costs of using caustic soda, sodium carbonate, and sodium sulphate must also be considered. Bayer's process has been the most extensively used and appears to require less power and labour than the others.—A. B. S.

Arsenious oxide; Preparation and testing of pure — R. M. Chapin. J. Ind. Eng. Chem., 1918, 10, 522–525.

To 2 litres of boiling water is added 150 grms. of powdered commercial arsenious oxide mixed with water, the whole is boiled for about 90 mins., or until the volume has been reduced to 1600 c.c., then allowed to settle, and the clear liquid filtered. If the liquid is not clear, it is heated to boiling with 2 grms. of calcium oxide, and then filtered. The filtrate is concentrated until 4 or 5 grms. of arsenious oxide has separated, and then filtered rapidly while boiling. A portion (equal to 1 gm. of dry substance) of the precipitate is tested for antimony by dissolving it in 10 c.c. of a mixture of equal vols. of ammonia (sp. gr. 0.9) and water, adding 10 c.c. of hydrogen sulphide solution, heating to boiling, and allowing to cool; antimony, if present, separates out as sulphide. Should the test for antimony be positive, successive crops of crystals must be tested until a negative test results: the antimony is practically all adsorbed by solid arsenious oxide. The antimony-free solution is then mixed with rather more than its own volume of concentrated hydrochloric acid, concentrated to saturation, filtered hot, and the filtrate cooled. The crystals formed are collected and sublimed.

—W. P. S.

Ceric oxychloride, produced by the electrolysis of cerous chloride. H. Arnold. Z. Elektrochem., 1918, 24, 137–138.

A dark brown amorphous deposit is produced on the cooler parts of the anode in the electrolysis of

fused cerous chloride. This powder is strongly hygroscopic and somewhat like ferric chloride, and consists of a mixture of ammonium chloride, ceric oxychloride (CeOCl_2), and water. Attempts to obtain the pure oxychloride failed. The oxychloride is only produced so long as the melted cerous chloride contains water. (See also J. Chem. Soc., Sept., 1918.)—J. F. S.

Nitrogen chloride: Convenient method of preparation of —. H. Rai. Chem. News, 1918, 117, 253.

NITROGEN chloride can readily be prepared by the action of a solution of bleaching powder on a saturated solution of ammonium chloride, at about 0°C ., without the use of hydrochloric acid or a solvent such as benzene. The apparatus must be absolutely free from grease and direct sunlight should be entirely excluded. (See also J. Chem. Soc., Sept., 1918.)—C. S.

PATENTS.

Sulphuric acid: Method of and apparatus for making —. L. A. Thiele, Columbus, Ohio. U.S. Pat. 1,267,012, May 21, 1918. Date of appl., Feb. 12, 1917.

A GLOVER tower is connected with an acid chamber by a number of pipes which enter the chamber tangentially and which are of different lengths and sectional areas, the smallest pipe having the greatest length and the largest pipe having the shortest length. A number of outlet conduits are arranged concentrically in the bottom of the chamber "on a diameter approximately half the diameter of the chamber."—L. A. C.

Catalytic substances; Preparation of — from natural ores containing iron oxide which contains water of hydration. H. Fritzweiler, Stolberg, B. C. Stuer, and Chem. Fabr. Rhenania, Aachen, Germany. Eng. Pat. 109,056, Aug. 22, 1917. (Appl. No. 12,072 of 1917.) Under Int. Conv., July 27, 1916.

THE crude ore, e.g., bog iron ore, bauxite, or the like, is finely powdered and compressed, with or without preliminary heating and without any binding substance. Disintegration of the catalyst in use is thereby prevented.—W. F. F.

Magnesium from compounds and mixtures of magnesium and calcium carbonate; Separation of —. H. W. C. Annable, Egham, Surrey. Eng. Pat. 117,483, July 13, 1917. (Appl. No. 10,202 of 1917.)

A MIXTURE of calcium and magnesium carbonates suspended in water is boiled in an autoclave under pressure (preferably about 4 atmos.) with just sufficient calcium chloride (or barium or strontium chloride) to convert the magnesium carbonate into magnesium chloride. The product is filtered and the magnesium precipitated from the filtrate by the addition of milk of lime, the calcium chloride produced being used for the treatment of fresh material. By passing carbon dioxide through a suspension of the precipitated magnesium oxide in water, a hydrated magnesium carbonate may be obtained, a different compound being produced according to whether the gas is passed into a cold or boiling solution. In treating mixtures in which the carbonates occur together as complex molecules (e.g., dolomite), it is necessary first to calcine the material in a current of air or steam, and precipitate the carbonates by passing carbon dioxide through a suspension of the product in water.

—L. A. C.

Carbon dioxide and solid sodium sulphite; Process of making —. H. Howard, Brookline, Mass., Assignor to General Chemical Co. U.S. Pat. 1,266,595, May 21, 1918. Date of appl., Nov. 22, 1915.

SODIUM bisulphite solution is introduced beneath the surface of a column of liquid containing sodium carbonate in suspension, the amount of liquid being insufficient to dissolve the sodium carbonate. Normal sodium sulphite and carbon dioxide are formed, the carbon dioxide being purified from sulphur dioxide in its passage through the liquor. (See also U.S. Pat. 1,164,649; this J., 1916, 254.)

—L. A. C.

Lead arsenate; Manufacture of —. I. P. Lihme, Lakewood, Assignor to The Grasselli Chemical Co., Cleveland, Ohio. U.S. Pat. 1,267,428, May 28, 1918. Date of appl., July 25, 1916.

LEAD oxide and arsenic acid in the proportion of their combining weights are caused to react in the presence of an amount of an acid-halogen derivative of silicon (hydrofluosilicic acid) less than 1% of the arsenic acid.—L. A. C.

Aluminium chloride; Process of making —. G. H. King and G. I. Roberts, Port Arthur, Tex., Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,268,015, May 28, 1918. Date of appl., June 15, 1917.

A PREHEATED suspension of finely divided alumina and carbon in chlorine is passed through a heated reaction chamber, and the aluminium chloride produced is condensed.—W. E. F. P.

Potassium sulphate and alumina; Method of recovering — from alunite. H. F. Chappell, Assignor to Mineral Products Corporation, New York. U.S. Pat. 1,268,433, June 4, 1918. Date of appl., July 23, 1913.

Her, calcined alunite is brought into contact with an aqueous solvent, and the undissolved alumina is separated from the hot solution of potassium sulphate produced. The latter is then cooled to effect deposition of potassium sulphate, and the mother liquor is used as solvent for a further quantity of calcined alunite.—W. E. F. P.

Potassium sulphate; Process of treating potassium-bearing silicates to obtain —. G. Sterling, Salt Lake City, Utah. U.S. Pat. 1,268,508, June 4, 1918. Date of appl., Sept. 17, 1917.

A FINELY-DIVIDED mixture of the silicate (3 parts), limestone (2 parts), and sodium sulphate (1 part) is heated to just below the temperature of vitrification, and stirred meanwhile, whereby potassium sulphate is produced and sublimed.—W. E. F. P.

Potassium and phosphorus compounds; Process of producing —. E. W. Hasiup, Bronxville, N.Y., and B. A. Peacock, Philadelphia, Pa. U.S. Pat. 1,270,515, June 25, 1918. Date of appl., Oct. 29, 1917.

A MIXTURE of finely-divided potassium-bearing silicate and phosphate rocks is treated with sulphuric acid in a closed, heat-insulated vessel until the mixture attains a temperature above 150° C. and a substantial portion of the silicate is decomposed. The mass is then treated with water and the liquid neutralised, to precipitate alumina and produce a neutral solution of the desired compounds.

—W. E. F. P.

Alumina; Treatment of insoluble —. H. F. Chappell, Assignor to Mineral Products Corporation, New York. U.S. Pat. 1,270,266, June 25, 1918. Date of appl., Mar. 1, 1916.

THE alkali-insoluble alumina of calcined alunite is converted into water-soluble compounds by mixing 100 parts with 210 parts of sodium carbonate and 110 parts of calcium oxide, and calcining the mixture at about 900° C.—W. E. F. P.

Brine [containing calcium and magnesium chlorides]; Method of treating —. E. O. Barstow, Assignor to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,270,589, June 25, 1918. Date of appl., May 12, 1917.

BRINE containing both calcium and magnesium chlorides is treated with excess of lime, and the precipitate, consisting of magnesium and calcium hydroxides, is separated, leaving substantially pure calcium chloride solution. The precipitate, in the form of a sludge, is then caused to react with a further quantity of the brine, whereby the calcium hydroxide is converted into magnesium hydroxide. The resultant liquor is then treated as before.—L. A. C.

Air or other gaseous mixtures; Process for separating the constituents of —. Ges. für Linde's Eismaschinen A.-G., Hölbriggelskreuth, Germany. Eng. Pat. 109,789, July 12, 1917. (Appl. No. 10,114 of 1917.) Under Int. Conv., Sept. 18, 1916. Addition to Eng. Pat. 21,735, Jan. 29, 1914.

AS an improvement of the process described in the chief patent (this J., 1915, 871) for separating the constituents of air or other gaseous mixtures containing, besides argon, two other gases which condense with difficulty, one of which boils more easily and the other less easily than argon, the rectifying column is cooled to about the boiling point of the more easily boiling liquefied gas under the pressure, above atmospheric pressure, prevailing in the column. For example, in the case of air, liquid nitrogen may be used as the cooling agent, being caused to evaporate under the pressure in the cooler. Liquid air or oxygen may also be used as the cooling agent, in which case, either the pressure is lowered by suction to attain the necessary temperature, or the pressure in the rectifying column is raised to that at which pure nitrogen liquefies at the temperature prevailing in the cooler.

—L. A. C.

Nitrogen; Production of — from the air. C. Andreucci, Rome. Eng. Pat. 117,333, Aug. 21, 1917. (Appl. No. 12,179 of 1917.)

ATMOSPHERIC air and hydrogen in theoretical proportions are exploded in an internal combustion engine; the exhaust gases consist of nitrogen and water vapour, from which the nitrogen is recovered.

—C. A. K.

Bromine; Process of producing —. R. Datta, Calcutta. U.S. Pat. 1,267,638, May 28, 1918. Date of appl., Aug. 17, 1916.

THE process consists in oxidising nitrosyl bromides and separating bromine from the products.

—W. E. F. P.

Oxides of nitrogen; Process of producing — and apparatus therefor. C. Rossi, Legnano, Italy. U.S. Pat. 1,266,717, May 21, 1918. Date of appl., Oct. 22, 1913.

SEE Fr. Pat. 463,821 of 1913; this J., 1914, 421.

Nitrogen compounds; Manufacture of metal —. R. Greulich, Ludwigshafen, Germany, and H. Lickfett, Rjukan, Norway, Assignors to Gebr. Glinini, Ludwigshafen. U.S. Pat. 1,268,240, June 4, 1918. Date of appl., Nov. 28, 1913.

SEE Fr. Pat. 463,232 of 1913; this J., 1911, 421.

Alkali perborates; Electrolytic process of making —. O. Liebknecht, Frankfurt, Germany, Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,268,369, June 4, 1918. Date of appl., Oct. 23, 1915.

SEE Eng. Pat. 14,292 of 1915; this J., 1916, 839.

Desulphurisation of gases and other fluids containing sulphuretted hydrogen. Eng. Pat. 117,387. See 11A.

Production of ammonium chloride during the working of blast furnaces. Eng. Pat. 102,146. See X.

VIII.—GLASS; CERAMICS.

Glass-tank furnace operation. R. L. Frink, Trans. Amer. Ceram. Soc., 1917, 19, 331—338.

THE production of seedy glass of low quality and erratic colour was traced to alterations to the checkerwork and to the partial collapse of a side flue, which had diminished the flow of air to the furnace. On re-setting the checkers and increasing the height of the chimney, good glass was produced. When the damper is lowered to "cut" the scum, the furnace temperature is also lowered, stiff, coloured, and seedy glass being produced. The correct procedure is to open both chimney- and air-dampers, and, if necessary, to supply more gas, so as to increase the temperature and so effect combination between the various constituents of the glass-batch. If the oil or gas used as fuel is allowed to impinge on the batch, glass, or port blocks before combustion is complete, carbon will be deposited and absorbed by the molten glass, with consequent discoloration. This can be avoided by mixing the air and gas thoroughly, previous to their combustion. It is important to maintain the checkerwork at a sufficiently high temperature, with proper regulation of the burner, pressure, air, and dampers; the top checker may be at 2200° F. (1200° C.), the bottom one at 1500° F. (815° C.), the flue at 900° F. (480° C.), and the chimney at 700°—800° F. (370°—430° C.).—A. B. S.

Glass; Formation and removal of bubbles in molten — R. M. Howe. Trans. Amer. Ceram. Soc., 1917, 19, 201–208.

THE removal of bubbles from glass depends on the frictional resistance of the glass and on the size of the bubbles, in accordance with the equation: $x = Ar^2/K$ where x = the rate of removal, A is a constant, r = the radius of the bubbles, and K is a constant. As K can never be made negligibly small, it is impossible to remove all the small bubbles by raising the temperature of the glass. The most effective means of removing small bubbles is to introduce larger ones into the glass, e.g., by dropping a potato into the molten glass; the small bubbles merge into the large ones and so are carried to the surface. The large bubbles are under a lower pressure than the smaller ones, so that the latter penetrate readily into them.—A. B. S.

Kaolins; Use of sulphuric acid in the sedimentation of — H. J. Schurecht. Trans. Amer. Ceram. Soc., 1917, 19, 130–145.

KAOLINS are purified by agitating them with a very dilute solution of sodium hydroxide, decanting the fluid with the clay in suspension, and adding just enough sulphuric acid to neutralise the alkali previously added and to facilitate the deposition of the kaolin. The treatment sometimes increases the plasticity of the kaolins, but this may be prevented by adding less acid. The formation of a black scum or discoloration is due to the use of an excess of sulphuric acid. The most suitable amount of acid must be ascertained by trial, as it differs with each clay. Usually it is desirable to employ rather less acid than is equivalent to the soda used.

—A. B. S.

Clays; Relation of salt to clay in the purification of — H. G. Schurecht. Trans. Amer. Ceram. Soc., 1917, 19, 460–478.

CLAYS may be purified by mixing them with very dilute solutions of certain electrolytes which cause the clay particles to remain in suspension whilst the coarser impurities settle out. If no electrolyte is added, some of the clay is carried down by the coarser particles. The lower the viscosity the greater the purification effected, but in the absence of electrolytes the proportion of clay kept in suspension is very low. To maintain a minimum viscosity in clay slips, it is more important to keep constant the ratio of electrolyte to clay than that of electrolyte to water. The author confirms Bleining's statement (this J., 1915, 906) that sodium silicate and sodium hydroxide are more effective than sodium carbonate; they also have a larger range of action. Viscosity tests show that 50–58% more clay can be separated from the crude material when the above-mentioned electrolytes are added than when plain water is used.—A. B. S.

Clays; Burning properties of some American refractory — H. G. Schurecht. Trans. Amer. Ceram. Soc., 1917, 19, 248–253.

TEST-PIECES of four clays were fired at the rate of 20° C. per hour and the pieces drawn from the kiln at intervals between 1210° C. and 1410° C. The porosities and volume-shrinkages were determined; also the temperature at which the burned pieces (each 7 in. × 1 in. × 1 in. and supported on fireclay knife edges 6 in. apart) broke under a load of 3 lb. applied transversely. It was found that the load-carrying capacity of refractory clays can be increased by burning them to higher temperatures, though vitrifiable clays are not improved so much as those of more open texture. The shrinkage in use is reduced by burning the ware at as high a temperature as possible.—A. B. S.

Refractory clays; Relation between the fusion point and composition of — R. J. Montgomery and C. E. Fulton. Trans. Amer. Ceram. Soc., 1917, 19, 303–311.

ON plotting the ratio of alumina to alumina plus silica of 57 clays as abscissae and their softening points as ordinates, the authors found that the points all lie below the eutectic curve found by Sosman (this J., 1917, 136) for mixtures of pure alumina and silica. The vertical distance between such points and the curve depends primarily on the percentage of fluxes present in the clays. The maximum activity of the fluxes present is shown in a clay containing about 14% of alumina (based on alumina plus silica=100). With high silica, beyond the eutectic point, the activity of the fluxes diminishes rapidly.—A. B. S.

Tiles; Effect of variation of pressure in forming dust-pressed — F. K. Pence. Trans. Amer. Ceram. Soc., 1917, 19, 94–101.

THE chief defects in dust-pressed tiles are due to unequal distribution of the pressure, to insufficient pressure, or, rarely, to excessive pressure. Tiles with high porosity and shrinkage have not been pressed sufficiently. Tiles which have been subjected to excessive pressure have a low porosity and low shrinkage. The use of excessive pressure in manufacture may cause vitrified tiles to blister or swell and glazed tiles to craze. The effect of pressure on the shrinkage of the tiles is important. The linear shrinkage and porosity curves correspond fairly closely. The minimum pressure likely to prove satisfactory under commercial conditions is 1000 lb. per sq. in.; 1800 to 2000 lb. per sq. in. is recommended as a satisfactory working mean.

—A. B. S.

Tiles; Effect of variation in pressure and moisture upon the forming of dust-pressed — F. W. Walker, jun., and E. G. Kerr. Trans. Amer. Ceram. Soc., 1917, 19, 409–427.

THE effect of a variable percentage of moisture and different pressures in making tiles of constant body-composition and fired at a uniform temperature was investigated. The pressure was applied by means of a large hand-press, the personal factor being eliminated by standardising the drop of the plunger and working the press only under the influence of gravity. Variations in pressure were secured by altering the area of the tiles. The plunger was first allowed to enter the box very slowly so as to compress the dust just sufficiently to eliminate most of the air. It was then raised to a constant height and allowed to drop under its own weight and momentum, two to ten blows being given. The tiles were burned at Mayer cone 10. Each blow after the second caused a constant decrease in the porosity of the tile, if the pressure remained the same. When the pressure per sq. in. was low, there was a considerable variation in porosity for any slight change in pressure, but with high pressures this variation was of less importance than a constancy of moisture content in the tiles. The effect of a variation in the moisture content was important in all cases. Representing the total pressure applied by K , it was found that at pressures below 0.05 K per sq. in. an increase in moisture content caused a decrease in porosity, but at higher pressures caused an increase in porosity. The practical limit of pressure for any moisture content is 0.2 K . The shrinkage increased with increase of pressure for all dusts up to 0.25 K ; beyond this the shrinkage decreased. The shrinkage at any given pressure above 0.05 K decreased with a decrease in the moisture-content.—A. B. S.

Tunnel kiln; Heat balance of a continuous — C. B. Harrop. Trans. Amer. Ceram. Soc., 1917, 19, 216—247.

The kiln investigated is of the moving-car type, 197 ft. long, 4 ft. 4 in. wide, and 8 ft. high from the top of the rails to the centre of the crown. It is heated by four hand-fired furnaces with horizontal grates, two on each side of the kiln and 108 ft. from the inlet end. The grate area of each furnace is 16½ in. by 39 in. The ash-pits are depressed and kept full of water. The waste gases pass out of the kiln, at a point 18½ ft. from the inlet end, to two vertical flues—one in each side wall of the tunnel—and down into the main flue which runs transversely underneath the kiln, and leads to a chimney, 126 ft. high by 5 ft. 6 in. diameter inside, at the base, and 5 ft. 6 in. by 15 in. at the top. Each car normally carries about 900 firebricks, weighing nearly 3 tons when burned, but, during the test, refractory ware of various sizes was burned along with the bricks and the average load was only 2.58 tons. The kiln holds 36 cars: 17 heating up, 4 in the high fire zone, and 15 cooling. The firebricks are burned to cone 14. One car is removed every two hours, another car of fresh bricks then enters the kiln, and all the remaining cars are advanced one car-length. The furnaces are usually fired immediately after moving the cars, but occasionally at shorter intervals. The grates are cleaned twice each 24 hours. The test covered a period of only six hours. The following results—expressed as percentages of the heat in the fuel supplied—were obtained:—3.27% in unconsumed combustible, 23.30% leaving kiln in dry combustion gases and dry excess air, 0.33% leaving kiln in the moisture which came in with the excess of air and air required for combustion, 1.79% leaving kiln in moisture evaporated from ash-pits, 3.67% leaving kiln in vaporised mechanical and hygroscopic water in combustion gases, 4.22% consumed in dehydration of clay and leaving in vaporised chemical water in combustion gases, 2.52% leaving kiln in unconsumed combustible matter in combustion gases, 17.07% leaving kiln in burned ware and clay in car structure, 0.20% leaving kiln in ironwork of car structure, 45.00% radiation and convection loss. The average excess of air in the flue gases was 352%, and by reducing it to 100% about 13.3% of the fuel would apparently be saved. If the greater part of this excess of air comes through the combustion-zone of the kiln, a reduction in its amount would lower the chimney-temperature, which is scarcely permissible. If, on the contrary, the greater part of the excess of air enters at the inlet end of the kiln, a reduction of the amount of air would result in a higher chimney-temperature, but would show no saving in fuel. About 203% of air leaked through the inlet end of the kiln. The total fuel consumption was 11.15% of the weight of the goods burned, or 725 lb. per thousand bricks.—A. B. S.

Porcelain bodies; Temperature-porosity-volume changes in — G. A. Loomis. Trans. Amer. Ceram. Soc., 1917, 19, 636—641.

The author recommends that temperature-porosity and temperature-shrinkage graphs of chemical and other hard porcelain bodies in commercial use should be plotted, so that their behaviour in burning may be accurately studied and loss in manufacture prevented. The maturing-temperature, the temperature at which over-firing begins, and the permissible range of temperature can be ascertained from these graphs. A body which remains constant in volume during a long temperature-interval, whilst the porosity remains at a minimum, is certain to be superior to a body with a shorter range.—A. B. S.

Bone-ash [in pottery]; Apatite, a substitute for — N. B. Davis. Trans. Amer. Ceram. Soc., 1917, 19, 125—129.

PRELIMINARY tests indicate that natural apatite of great purity may be used as a substitute for bone-ash in the manufacture of china ware. Commercial precipitated calcium phosphate is unsatisfactory on account of the impurities present, but this objection does not appear to apply to selected pieces of the mineral phosphate.—A. B. S.

Marquardt porcelain and magnesium aluminate; Production of special refractories, viz., — F. H. Riddle. Trans. Amer. Ceram. Soc., 1917, 19, 397—408.

A CONTINUATION of an investigation on the manufacture of porcelain tubes for pyrometers (Howat, this J., 1917, 715). The materials are blunged with water to form a slip, which is passed through a 120-mesh sieve and then filter-pressed. For making pressed tubes, a solution of 0.16 part of gum tragacanth per 100 parts of dry body is added and the mass is thoroughly pugged in a pill-mixer for about 20 mins. It is afterwards forced through a small hydraulic pipe-press. The collars and closed ends must be fixed on afterwards. For casting, sufficient water is added to the filter-press cakes to make 60% of the dry weight and, after thorough blunging, sufficient of a solution of 3½% sodium silicate and 10% sodium carbonate is added to thin the slip so that 200 c.c. will run through a Kleininger viscometer in 2 mins. (Technical Paper 51, U.S. Bureau Standards; see also this J., 1917, 875). The plaster moulds are cast around a cold-drawn steel rod with a rounded end, in which a hole $\frac{1}{8}$ in. diameter and $\frac{3}{4}$ in. deep is drilled. A steel pin, about 3 in. long is fitted loosely into the hole, and when withdrawn provides an air-vent at the end of the mould. When using the mould this air-vent is plugged with a small piece of wire which projects about $\frac{1}{2}$ in. into the mould and is kept in place by soft clay. The mould is filled with the slip, which is allowed to stand for 1—4 mins. (according to the diameter and thickness of the tube); afterwards the wire is drawn out whilst the mould is turned round and the surplus slip is poured out. If the wire is drawn too soon, the vent will be blocked with slip; if it is left in after the slip is poured out, the tube will collapse. The tubes remain in the moulds for 24 hrs.; they are then withdrawn and laid close together on sheets of plate glass and dried for 24 hrs. The tubes are suspended by their flanged heads in tall saggars, each 14 in. x 3 in. and containing only one row of tubes, and burned at cone 1. They are then sprayed with a glaze-mixture corresponding to $\text{CaO}, \text{Al}_2\text{O}_3, 4\text{SiO}_2$ and re-burned at cone 17 in 5 or 6 hrs., rapidity of heating being important. During the burning, the tubes must swing freely and be heated uniformly or they will warp. If two rows of tubes are burned in a sagger they will warp. The tubes produced were similar in character to the German tubes, but the latter are rather thicker and sag slightly less when pieces 8 in. long are placed on supports 7 in. apart and are heated to cone 22.

Magnesium aluminate (spinel, $\text{MgO}, \text{Al}_2\text{O}_3$) is the most stable compound of the system lime-alumina-magnesia. Its fusion point is 2135° C., as compared with 1816° C. for Al_2SiO_5 , 1387° C. for $5\text{CaO}, \text{Al}_2\text{O}_3$, 1587° C. for $\text{CaO}, \text{Al}_2\text{O}_3$, 1725° C. for $3\text{CaO}, 5\text{Al}_2\text{O}_3$. It may be prepared by grinding a mixture of 45.2% of flocculent magnesium carbonate or Californian magnesite with 54.8% of calcined alumina in a ball-mill, tempering the product with water, making it into balls of about 1½ in. diameter, and calcining these at cone 22—30. The calcined

material is ground dry to three sizes (40F, 20F and 20—40). The material is non-plastic and cannot be cast satisfactorily. If made into a paste with water, it can be shaped by means of a "jolley" in moulds coated with oil in which fine graphite is suspended. The ware should be removed from the moulds as soon as possible, dried, and burned. At cone 17, the material forms a cream-white, porous, biscuit ware, but at cone 35 it vitrifies to a dense, translucent body, not easily attacked by molten slag or iron, sensitive to exceedingly rapid cooling, but withstanding ordinary usage. It should be useful for furnace linings, crucibles, tubes, combustion-boats, and similar products.

—A. B. S.

Silica bricks; Volume-changes of some commercial — on heating. D. W. Ross. Trans. Amer. Ceram. Soc., 1917, 19, 83—93. (See also this J., 1917, 718.)

Silica bricks which have not been heated sufficiently during manufacture increase both in porosity and "outside volume" when reheated to 1400° C., 1450° C., or 1500° C., the increase in porosity being roughly proportional to the increase in the volume of the solid material. With material which has attained equilibrium at 1450° C. there is very little change on reheating at 1500° C., and there may even be a slight decrease in the outside volume, due to an increase in the density of the solid material. By comparing the percentage increase in volume which occurs on a single reheating to each of three higher temperatures or on repeated heatings at a single temperature, an idea can be obtained as to how far each test-piece was from equilibrium at the reheating temperature. The amount of skin surface or surface of the original brick on the test-pieces did not affect the results. Test-pieces of less than 150 c.c. volume tend to give inaccurate results and still larger pieces are preferable. Increase in pore-space is usually caused by and is proportional to an increase in the volume of the solid material. The influence of small cracks on the increase in volume is usually negligible. An effect of minor importance is the fluxing and consequent shrinkage of some particles which tend to counteract any increase of pore-space. The extremes of porosity in the original bricks were 22.64% and 31.96% respectively. A volume-expansion of 1.45% at 1400° C., 1.38% at 1450° C., and 5.66% at 1500° C. may be expected when commercial (American) silica bricks are reheated at these temperatures. When such bricks are built into a furnace, a somewhat greater expansion may be anticipated. The specific gravity of a silica brick also affords an easy and accurate means of determining the degree to which it has been burned, raw silica having sp. gr. 2.59—2.66 and silica completely inverted to tridymite and cristobalite sp. gr. 2.27 and 2.33 respectively.—A. B. S.

Grog in fireclay bodies; Effect of size of —. F. A. Kirkpatrick. Trans. Amer. Ceram. Soc., 1917, 19, 268—290.

Grog was made by crushing high-grade firebricks (made from a mixture containing 50% flint fireclay) in a wet-pan and then screening it through sieves so as to obtain the following sizes: (a) 4—8 mesh, (b) 8—12 mesh, (c) 12—20 mesh, (d) 20—40 mesh, (e) 40—80 mesh, (f) 80-mesh—dust. The various fractions were mixed with clay in different proportions and the mixture was wetted and pugged. Test-pieces were made by hand-moulding, drying in air for at least 3 days, then at 65° C. for one day, and finally at 100° C. for 2 days. Some of the test-pieces were burned at cones 10, 12, and 14. *Tests using grog particles of one size.*—The body with grog of size *f* vitrified more rapidly than the others.

The 80-mesh formed a dividing line between the coarse or slowly vitrifying and the fine or rapidly vitrifying grog sizes. Some fine grog was necessary for development of high strength by vitrification. From sizes *a* to *e*, the strength increased with the porosity, probably due to drying cracks; the size of these cracks decreased with the coarser grog. From sizes *a* to *c*, the strength increased with the increase of porosity; it also increased with the surface factor of the grog. Size *e* gave the most porous bodies. Specimens containing the larger sizes of grog gave the best quenching tests. *Tests using grog of various sizes.*—The strength of raw bodies varied as the surface-factor in the mixtures containing grog sizes *a*, *b*, and *c*, and *b*, *c*, and *d*, respectively, but not in those containing grog sizes *c*, *d*, and *e*, and *d*, *e*, and *f*. The strength varied directly with the porosity in the first three mixtures mentioned, but inversely as the porosity in the fourth mixture. Mixtures of grog of different sizes gave denser bodies than single sizes of grog, provided the smaller grog-particles packed well into the voids between the larger ones. Grog of size *e* fits into the voids between either size *c* or *d*, and a mixture containing 25—66.7% of size *d*, 0—25% of size *c*, and 33.3—66.7% of size *f* approached the theoretical ratio and gave the strongest (unburned) product, though most of the particles in size *e* were too large. Mixtures of equal parts of sizes *a*, *b*, and *c*, and of equal parts of sizes *d* and *e*, and size *f* alone gave the densest, but not the strongest bodies. If a mechanical analysis of the grog mixtures is made, that one will give the strongest test-pieces which yields a graph the lower part of which is parabolic and the upper part is a straight line. In the burned state, the surface-factor affords an accurate means of judging the strength of the material, but the porosity is often misleading. The strength increased with a higher burning temperature. Mixtures containing grog sizes *b*, *c*, and *d* gave the best quenching tests. Grog for glass-pots and similar bodies should not contain too much fine material or that of intermediate sizes, as this is a source of low strength and cracking during drying. The best bodies for this purpose have compositions corresponding closely to the parabola previously mentioned, and have a modulus of rupture of 275—300 lb. per sq. in. in the dried state and 3500—4400 lb. per sq. in. in the burned state. For saggers having walls and bottoms 1 in. in thickness, a mixture of 1 part of grog of size *a*, 3 parts of size *b*, and 1 part of size *c* is recommended where resistance to repeated heating and cooling is desired more than strength, whilst a mixture of two parts of size *c* and 1 part of size *d*, or the use of size *c* alone, will give greater strength at some sacrifice of durability. Both very large and very fine grog are alike undesirable in saggers.—A. B. S.

Firebricks; Modified load-test for —. J. B. Shaw. Trans. Amer. Ceram. Soc., 1917, 19, 498—506.

In order to classify high-grade firebricks more closely than is possible when a constant load is applied, the author applies the pressure by means of a spring so that the load diminishes when the brick begins to yield or is crushed. It is suggested that a test under diminishing pressure bears a closer resemblance to furnace conditions than a test with a constant load.—A. B. S.

Lead glazes; Cost of raw —. H. F. Staley and L. C. Hewitt. Trans. Amer. Ceram. Soc., 1917, 19, 659—673.

A SERIES of 108 glazes was composed of the following ingredients: white lead at 3½d. per lb., felspar,

whiting, clay, and flint each at $\frac{1}{2}$ d. per lb. Replacement of lead oxide by felspar did not affect the texture, but made the glazes more refractory. Increasing the lime and reducing the lead oxide and felspar in equal proportions made the glazes more refractory and tended to make them matt. An increase in the clay content made the glazes more refractory and dull. An increase in flint usually made the glazes more fusible and glossy. Increasing the temperature increased the number of bright glazes, especially those rich in lead oxide. For use at cones 05–3, the cheapest bright glazes cost 1-4d. –2-25d. per lb. The cheapest silky matt glazes cost 1-65d. –2-25d., and the cheapest watery matt glazes 1-65d. –2-25d. per lb. In the discussion, it was pointed out that the cost of the glaze materials is so small a part of the total cost of the ware, that the production of a minimum amount of defective ware, rather than the cost of the glaze, should have the chief consideration.—A. B. S.

Lead glazes; Physical and chemical properties of lead compounds and their use in raw —. F. A. Morgan. Trans. Amer. Ceram. Soc., 1917, 19, 442–448.

LITHARGE and red lead may be substituted for white lead (usually with a saving in cost) if the necessary adjustment is made in the viscosity of the glaze and the same equivalent of PbO is used. The "fumed oxides" are equal in purity to white lead and though they have a higher sp. gr. they will remain in suspension longer on account of their great fineness. When dry, the oxide glazes are harder and so produce less dust than those containing white lead.—A. B. S.

Lead glazes; Study of three-component normative systems in raw —. W. G. Whitford. Trans. Amer. Ceram. Soc., 1917, 19, 312–320.

The compositions of various raw glazes were represented in triangular diagrams with the following end-members:—Anorthite series: orthoclase (potash felspar), anorthite (made from whiting and kaolin), and lead metasilicate (made from white lead and flint). Wollastonite series: orthoclase, wollastonite (made from whiting and flint), and lead metasilicate. Zinc silicate series: orthoclase, zinc metasilicate (made from zinc oxide and flint), and lead metasilicate. The glazes were applied to white, biscuit wall-tiles and burned at cones 05, 02, 1, and 3 respectively for from 12 to 16 hrs. When the end-members are properly chosen, the normative system of glaze calculation and blending (this J., 1912, 1128) gives series of glazes whose physical properties vary in a regular manner. The glazes in the anorthite series are more refractory than the others and contain a larger proportion of matt glazes. Mattness is a function of temperature and composition; it is determined by the anorthite content and bears no relation to the oxygen ratio. Most of the glazes of the wollastonite series were bright, the division between these and the dull glazes being fixed at each temperature by the wollastonite content. Most of those in the zinc silicate series were bright glazes and stoneware enamels, but a few matt and some truly crystalline glazes were produced.—A. B. S.

Fritted glazes; Control of fusibility in —. H. F. Staley and R. J. Rieky. Trans. Amer. Ceram. Soc., 1917, 19, 642–652.

WITHIN fairly large limits, equal melted weights of potassium, sodium, calcium, magnesium, zinc, lead, and boron oxides have about the same effect on the fusibility of glazes. Two-thirds of a pound of flint increases the refractoriness of a frit rather more

than 1 lb. of felspar. Enamels high in felspar are better in every way than those high in flint. Enamels rich in lime are pink in colour.—A. B. S.

Matt glazes; Effect of porosity of the body and moisture content of the glaze in the application of —. F. S. Hunt. Trans. Amer. Ceram. Soc., 1917, 19, 428–441.

THREE representative raw lead matt glazes, with different moisture contents, were applied to tiles of a constant composition, but with porosities varying from 14 to 31%. It was found that the weight of glaze per unit area determines the texture of the glaze surface. The best matt effects were produced when the burned glaze had a weight of 0.100 to 0.135 grain per sq. cm. of tile area.—A. B. S.

Glazes; Crawling of matt —. C. F. Binns and M. E. Saunders. Trans. Amer. Ceram. Soc., 1917, 19, 597–600.

THE factors which chiefly affect the tendency of matt glazes to crawl are the burning of the body and the grinding of the glaze. The glaze fell off some short-fired pieces in large flakes, even when mucilage had been added to the glaze-slip. With over-ground material, the addition of mucilage is useful, especially when all the clay in the glaze is calcined. The best results were obtained with a glaze made from calcined clay, ground for half an hour, mixed with mucilage, and applied to a well-fired body which had previously been soaked to saturation.—A. B. S.

Bristol glazes compounded on the eutectic basis; Practical application of —. A. S. Watts. Trans. Amer. Ceram. Soc., 1917, 19, 301–302.

THREE glazes were selected from the eutectic area mentioned in a previous paper (see this J., 1917, 716), having the following compositions:—

		A	B	C
Felspar	...	60.87	57.07	50.10
Whiting	...	6.25	5.86	9.01
Zinc oxide	...	7.76	10.69	9.73
China clay	...	7.06	8.15	9.07
Ball clay	...	7.06	8.15	9.07
Flint	...	11.00	10.08	13.02

They were mixed with water to form a slip weighing 22 oz. per pint. When properly ground and mixed, these glazes are satisfactory between cones 3 and 14 on a large variety of clays. In no case was crawling or crazing noted. At cones 3, 4, and 5, these glazes produce fine smooth enamels, suitable for novelty pottery and cooking ware; at cone 10 they are opaque enough for use on buff-burning clay, and at cones 12 to 14 are useful for electrical porcelain.—A. B. S.

Terra-cotta; Pinholing and peeling on —. H. Wilson. Trans. Amer. Ceram. Soc., 1917, 19, 209–215.

"PINHOLES" are caused by small tongues of under-slip which rise through the glaze and leave a clean hole with a distinct projection. They are not merely small blisters or holes in the glaze. Pinholes are produced when a second coating of under-slip or a coating of glaze is sprayed on to dry terra-cotta, when no barium salt is added to a body containing soluble salts, when an excess of barium carbonate is added to the clay, and when the dry ware is brushed over with a 10% solution of barium chloride or fluoride previous to slip-coating and glazing. In the case of all glazed ware, pinholing is worse in glazes which flow least in firing. Pin-

holes are not prevented by rubbing the dried and glazed surface, by avoiding the use of oil, or by brushing away all dust before coating the ware. They are not caused by particles of plaster from the mould or by the slip- or glaze-coatings being too dry before a further coating is applied. They are partially prevented by removing the surface of the ware with sand-paper, by firing the underslip with no glaze covering, and by adding 2% of a mixture of barium carbonate and fluoride. They are wholly prevented or remedied by re-spraying the burned pieces with glaze and reburning or, preferably, by adding 2% "gum arabic sorts" to the underslip and 3% to the glaze.—A. B. S.

Magnesia-alumina-silica mixtures; A deformation study of —. A. S. Watts. Trans. Amer. Ceram. Soc., 1917, 19, 453—456.

THE most fusible mixture of magnesium carbonate, china clay, and flint contained 20% MgO, 20% Al_2O_3 , and 60% SiO_2 , and had a deformation temperature of cone 12. The deformation was very rapid. Mixtures containing less than 40% SiO_2 curled forward at cone 8, but this was not true deformation. Mixtures containing 35% MgO or more shrank considerably at cone 10.—A. B. S.

Baryta-alumina-silica mixtures; A deformation study of —. A. S. Watts. Trans. Amer. Ceram. Soc., 1917, 19, 457—459.

THE most fusible mixtures of barium carbonate, china clay, and flint contained 35% BaO, 10% Al_2O_3 , 55% SiO_2 , and 40% BaO, 10% Al_2O_3 , 50% SiO_2 respectively. They both deformed completely at cone 6. Five other mixtures deformed at cone 7, ten at cone 8, seven at cone 9, and four at cone 10. No mixture of barium carbonate and flint deformed at or below cone 10. The ternary mixtures containing 10% Al_2O_3 fused to clear glasses; those with only 5% Al_2O_3 were opaque.—A. B. S.

[Crystalline glasses.] *Investigation of the ternary system willemite-tephroite-soda glass.* H. C. Arnold. Trans. Amer. Ceram. Soc., 1917, 19, 674—695.

WILLEMITE ($2\text{ZnO} \cdot \text{SiO}_2$), tephroite ($2\text{MnO} \cdot \text{SiO}_2$), and soda glass ($\text{Na}_2\text{O} \cdot 2\text{SiO}_2$) were prepared synthetically, and mixtures of these in various proportions were heated to 1175° C. in 3½ hrs., the results being plotted on a triangular diagram. The most promising specimens were re-melted at cone 12 in 24 hrs. and cooled for 62 hrs. Long acicular crystals of willemite grow most readily in a mixture of equal parts of willemite and soda glass. A larger proportion of willemite produces crystals which are too small to be satisfactory. Crystallisation is less definite in the presence of manganese than in that of zinc. Three compounds of manganese are produced: hausmannite, Mn_3O_4 , is first formed, its development being greatly increased on prolonged heating at a temperature corresponding to moderate viscosity of the glaze. If the mass is free to attack silicious material, rhodonite (manganese trisilicate) is formed, but otherwise tephroite (manganese orthosilicate). Evidence of immiscible liquids was found in various parts of the field. The material with the lowest melting point (772° C.) is opposite the glass-willemite eutectic and close to the glass-tephroite eutectic in the triangular diagram.—A. B. S.

Chrome-tin colours at cone 9. R. H. Minton. Trans. Amer. Ceram. Soc., 1917, 19, 378—396.

To develop a pink colour underglaze at cone 9, the glaze must contain tin oxide. The composition of

the glaze appears to be more important than that of the stain. Re-firing weakens the colour and may destroy it. Strontium chromate and barium chromate produce stronger colours than any other chromate used, with chromic oxide as the next best. Zinc chromate also produces a strong colour. Lead chromate does not yield dark reds and causes milkiness. Potassium bichromate is the best source of chromic oxide for clear reds. Calcium fluoride is superior to calcium carbonate or sulphate. Milkiness appears to be the result of incomplete reaction between the chromic oxide and the lime (depending on the source of each) and on insufficient time. Unwashed stains are preferable for the stronger colours.—A. B. S.

Overglaze colours at cone 6—7. H. Wilson. Trans. Amer. Ceram. Soc., 1917, 19, 653—658.

To glaze a large number of pieces of ornamented terra-cotta in two colours, the raised work being white on a coloured background, the whole of the pieces were first sprayed with white glaze slip containing gum arabic, and a coloured overglaze stain was then applied with a fine air brush. Any stain which had fallen where it was not required was removed (when dry) with a stiff brush, the gum in the glaze making it sufficiently hard to resist this treatment. A final coat of a dilute solution of gum arabic was applied in some cases to prevent the overglaze from "dusting." The pieces were then fired in the usual way at cone 6—7. For yellow backgrounds, a mixture of a commercial yellow stain, powdered rutile, and uranium sulphate or nitrate, ground with water, was used; for pink or rose backgrounds, a mixture of tin oxide, whitening, potassium bichromate, and flint; and for brown backgrounds a mixture of this or a chrome-green stain with the yellow mixture mentioned above. For violet backgrounds, a mixture of china clay, zinc oxide, flint, sodium nitrate, and cobalt oxide was used, and for green backgrounds, a mixture of cobalt oxide and uranium nitrate stains.

—A. B. S.

Enamels; American clays for floating —. J. B. Shaw. Trans. Amer. Ceram. Soc., 1917, 19, 339—360.

A TENNESSEE and a Florida ball clay were each found to be satisfactory substitutes for the Valendar (German) clay commonly used for keeping the non-plastic ingredients of an enamel slip in suspension and for making the slip of suitable consistency. For measuring the viscosity of the slips a viscometer was used which has two outlets 3/32 in. and 5/32 in. diameter respectively. The viscosity is found by dividing the volume of slip flowing through one outlet by that which flows simultaneously through the other, and so avoids referring the viscosity to water as unity. Enamel slips of high viscosity and low sp. gr. give the best results. By keeping the consistency of the slip (*i.e.*, the viscosity divided by the sp. gr.) constant, more uniform results are obtained in enamelling. The quantity of flocculating agent (aluminium or magnesium sulphate) present in the slip is unimportant so long as sufficient is added to flocculate the clay; 0.5% of magnesium sulphate, as ordinarily used in commercial practice, was found to be better than stannic chloride (0.5%) or borax (3%). The use of a flocculating agent prevents the enamel from flowing down the sides of the ware in an undesirable manner, even when the slips have a low sp. gr. The maximum viscosity obtained was 6.5, but a value as low as 4.5 is permissible if the volume-weight of the slip is about 150 grms. per 100 c.c.

—A. B. S.

Enamel surfaces under the microscope. E. P. Poste. Trans. Amer. Ceram. Soc., 1917, 19, 146—159.

In continuation of previous work on the resistance of enamels to acids (this J., 1917, 879), various pieces of enamelled ware (including pieces fired above and below the usual temperature) were examined under a microscope with a magnification of 75 diameters. The results showed that marked variations in the physical condition of the enamel are brought about by different heat-treatments. Similar variations were observed in samples of commercial enamelled ware. In under-burned pieces, the enamel consists chiefly of a glassy matrix containing fine bubbles and particles of unfused material. In normally burned enamels, the unfused matter is absent and the bubbles run together forming larger ones. In over-burned enamels, the bubbles continue to combine until they produce surface-pitting visible to the naked eye. Enamels which had been treated with warm hydrochloric acid for several hours were also examined. The acid tends to soften the enamel, to dissolve some of the constituents, and to leave behind a fine white powder which can be rubbed off when the surface is dry. The paper is illustrated with 14 photomicrographs.—A. B. S.

Latent heats of fusion of lime and magnesia. Washburn. See VII.

Instrument for measuring plasticity. Emley. See IX.

PATENTS.

Glass furnace; Electric —. J. O. Erskine, Steubenville, Ohio. U.S. Pat. 1,267,317, May 21, 1918. Date of appl., Nov. 21, 1917.

Two electrodes are partially immersed in the glass-producing materials and an electric current is passed so as to melt the materials and produce glass continuously. The charge forms the sole resistance for generating the heat by which melting is accomplished. The melting and working chambers of the furnace may each be provided with a separate set of partially immersed electrodes.—A. B. S.

Sheet glass; Method of and apparatus for drawing —. T. H. Chadwick, Arnold, Pa. U.S. Pat. 1,267,849, May 28, 1918. Date of appl., Nov. 23, 1916.

A continuous sheet of glass is drawn from the molten "metal" by means of a gripping device and elevator. The edges of the sheet are cooled by an air-blast and the glass is then cut into individual sheets by a travelling oxy-acetylene flame, the severed sheets being moved at a more rapid rate than the continuous one.—A. B. S.

Kilns for earthenware, tiles, and other articles. W. Bennett, Stoke-on-Trent. Eng. Pat. 117,147. July 16, 1917. (Appl. No. 10,257 of 1917.)

A GAS-FIRED kiln or oven in which the flame is equally distributed over the kiln bottom and through the walls is constructed with a gas flue, *a*, extending longitudinally at one side of the kiln, and connected with a series of transverse conduits, *b*, which lead to a combustion chamber, *c*, placed midway in the kiln and extending the whole length of the latter. Parallel to the transverse gas con-

duits and alternating with them are air passages. The products of combustion from the chamber, *c*,

pass up around the sides of the kiln through flues, *f*, to the chimney. Means of regulating the gas and air are provided.—A. B. S.

Tunnel kilns [for pottery]; Continuous —. G. H. Benjamin, New York. Eng. Pat. 117,383, Nov. 12, 1917. (Appl. No. 16,592 of 1917.)

The kiln is heated by a series of internal horizontal flues or combustion chambers placed end to end and built up in sections to allow them to expand or contract without injury. Air and gas are supplied to these chambers under pressure. The products of combustion are withdrawn and used in an external air-heater, to heat the air required for the combustion of the gas used as fuel and also for supplying a current of air to the interior of the oven. The circulation of the air is effected by means of an external pump.—A. B. S.

Glaze used in the manufacture of pottery and like articles. W. P. and W. H. Edwards and W. Mollart, Stoke-on-Trent. Eng. Pat. 117,047, Feb. 13, 1918. (Appl. No. 2579 of 1918.)

CALCINED shells are ground to a very fine powder, mixed with water, and added to ordinary potter's glaze in the proportion of 2 oz. to 1 cwt. of glaze. The mixture is agitated for about 5 mins., when it thickens, but may be diluted with water to a convenient consistence. It is claimed that the use of the powder produces a better distribution of the glaze and reduces the amount of glaze material (particularly lead compounds) used.—A. B. S.

Platinizing earthenware, pottery, and the like. F. J. Kettel, Beckenham, Kent, A. Gasch and T. A. Dean, London. Eng. Pat. 117,432, May 13, 1918. (Appl. No. 8003 of 1918.)

The article is covered with a solution or emulsion of platinum chloride, phenylhydrazine, and glycerol, heated sufficiently (e.g., to 850°—900° C.) to reduce the platinum to the metallic state, and then allowed to cool gradually. The solution or emulsion is prepared by dissolving 3 grms. of platinum chloride in the least possible quantity of water, adding 12 c.c. of glycerol, and heating the mixture to 100° C., at which temperature it is maintained for about 1½ hrs. The phenylhydrazine is then added, drop by drop, stirring after each addition, and after settling, the clear liquid is decanted.

Refractory furnace lining and process of making. S. B. Newberry, Cleveland, Ohio. U.S. Pat. 1,267,686, May 28, 1918. Date of appl., June 25, 1917.

LIMESTONE or magnesian limestone is ground and mixed with 2–10% of oxides of the aluminium-iron group, capable of forming fusible compounds with lime and substantially free from silica. The mixture is calcined to form a dense clinker.—A. B. S.

Aluminous abrasives. T. B. Allen, Toronto, Canada, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pats. (A) 1,268,532 and (B) 1,268,533, June 4, 1918. Dates of appl., (A) Nov. 11, 1916; (B) Aug. 7, 1917.

(A) An aluminous ore containing 15% or more of iron oxide and silica is heated to fusion in a reducing atmosphere and is then allowed to cool and crystallise. (B) A crystalline fused aluminous abrasive material containing more than 60% of crystalline alumina and more than 10% of silica, iron oxide, and titanium oxide, the major portion of the crystals being less than 0.01 mm. in diameter.—A. B. S.

IX.—BUILDING MATERIALS.

Paving bricks from blast-furnace slag. J. B. Shaw. Trans. Amer. Ceram. Soc., 1917, 19, 507–522.

THE author claims that the possibility of using American slags for the manufacture of paving bricks has been conclusively proved. The characteristics of the bricks depend more on the manner in which the slag is cooled than on its composition. The following process is recommended: The slag from the furnace is poured into a tilting frit-furnace and any additional materials (such as 10–20% of silica or iron oxide) required to bring it to a desired composition are then added. The mixture is brought to a quiet fusion, and run into moulds. The moulds with their contents are immediately placed in an annealing furnace at the softening temperature of the bricks, and are maintained at this temperature until the bricks are uniform throughout; or the bricks are buried in sand. The rate and mode of annealing are of great importance and determine whether tough, good bricks or brittle ones are produced.—A. B. S.

Gypsum: Measurement of the time of set of calcined — W. E. Emley. Trans. Amer. Ceram. Soc., 1917, 19, 573–584.

THE normal consistency of the plaster is first determined, using the Southard instrument as recommended by the American Society for Testing Materials. From this is ascertained the amount of water to be added to 300 grms. of the sample. This quantity of water is placed in a casserole and 300 grms. of the sample placed in it, without splashing, in less than 2 secs. The plaster is allowed to soak quietly for 58 secs., the mixture is stirred vigorously for 1 min., and is then poured into a mould made of hard rubber and dipped in melted paraffin. At 1-minute intervals it is tested with a standard Vicat needle. The time which elapses between the adding of the sample to the water and that when the needle no longer penetrates to the bottom of the mass is recorded as the time of final set. The mould can be cleaned readily, if it is first heated very gently. No method has been found for determining the time of initial set, but as this does not appreciably affect the ultimate properties of the plaster, it is unimportant.—A. B. S.

Plasticity [of wall-plasters]; Instrument for measuring — W. E. Emley. Trans. Amer. Ceram. Soc., 1917, 19, 523–533.

As the plasticity of a wall-plaster is usually judged by means of a trowel held at an angle of 10°–15° to the wall, an instrument was devised in which the trowel is replaced by a cone mounted point downwards, the side of which makes an angle of 10° with the horizontal, and the wall is represented by a disc of plaster of Paris of known absorption mounted on a vertical shaft, below and concentric with the axis of the cone; the shaft is threaded and runs through a fixed nut. The material of which the plasticity is to be measured is placed on the disc and the latter is forced upwards against the cone with a spiral motion at a constant speed (this being more convenient than moving the "trowel" over the disc). The pressure exerted is analogous to that component of the force exerted by the trowel which acts normally to the wall; the tangential force of the turning movement of the disc over the face of the cone brings into play that component of the force which is parallel to the wall. The cone is so mounted that either of these forces is able to cause motion independently of the other, this motion being transmitted through a system of levers to one of two bars suspended like pendulums. When a constant force moves the cone, the bars swing out until in equilibrium with the force of gravity acting on them; both the cone and bars then become stationary and the force acting on the cone is directly proportional to the size of the angle through which the bars have moved. The machine is run at a constant speed for a definite time—say 3 mins. A tangential force of (say) 2 grms. per sq. cm. is arbitrarily assumed as the starting point and a boundary ordinate erected through this point, the other being at a point representing 3 mins. later. The position of the first ordinate depends on the consistency of the paste under examination, but the average value of the tangential force between the two ordinates (which is the plasticity-figure) is independent of the consistency. The plasticity-figure for limes lies between 5 and 20. The ratio of the tangential to the vertical force with clays is so much greater than with limes that the machine would have to be modified to make it suitable for use with clays.—A. B. S.

Volume changes of some commercial silica bricks on heating. Ross. See VIII.

PATENTS.

Concrete and the like. W. J. Stewart, London. Eng. Pat. 117,504, July 25, 1917. (Appl. No. 10,690 of 1917.)

AN aggregate of low specific gravity is made by moulding clay into spheres of various sizes (e.g. $\frac{1}{4}$ in., $\frac{1}{2}$ in., and $\frac{3}{4}$ in. diameter), burning these at a suitable temperature, and glazing them. Before the fused glaze has become hard, the spheres are caused to pick up sand so as to give them a rough surface. If a vitreous clay (such as that used for making blue bricks) is employed, the glazing and sanding are unnecessary. The aggregate thus prepared may be made into concrete by arranging it in a mould in a series of layers of different sizes and then filling the mould with the cement matrix from below upwards.—A. B. S.

Binder for roads, etc., and process for making same. E. A. Paterson, Thorold, Canada. U.S. Pat. 1,266,618, May 21, 1918. Date of appl., Jan. 5, 1916.

A BINDER for stony agglomerates is made by treating a solution of an alkali silicate (sodium silicate)

with a soluble haloid salt of an alkaline-earth (calcium chloride) and with an acid capable of combining with the alkali-metal base of the silicate to form a salt which, in solution, is inert to organic substances, and is gradually removed by weathering. Part of the silicic acid is liberated in the free state and part forms insoluble calcium silicate. —A. B. S.

Fibrous composition and process of making the same. G. A. Henderson, St. Albans, W. Va. U.S. Pat. 1,270,732, June 25, 1918. Date of appl. July 30, 1917.

VEGETABLE material (such as hard wood) consisting of fibres of exactly uniform thickness but of irregular lengths and breadths, is passed through an open-ended vat containing a hot binding and preservative agent so as to expand the pores of the fibres, vaporise the moisture in them, and fill the pores with a predetermined amount of preservative. The steam produced is withdrawn from the vat and the material is compressed into shape. —A. B. S.

Timber; Kilns and chambers for drying —. M. Halkes, Dunston, Lincoln, Eng. Pat. 117,040, Jan. 11, 1918. (Appl. No. 702 of 1918.)

Saturation of porous fabrics [paper-board] with asphalt. U.S. Pat. 1,268,430. See V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast-furnaces; Hot blast for —. O. Simmersbach. Stahl u. Eisen, 1918, 38, 697–703.

In the Cowper hot-blast stove the combustible gases are distributed uniformly over the whole of the brickwork from the centre to the walls and pass through all the channels with a uniform velocity, usually about 1 metre per sec. With low velocities the gas passes straight up the openings and gives up a relatively small part of its heat, but as the velocity is increased the gas passes up spirally with much better results. The proportion of heat given up by the hot gases to the walls is equal to Cw , where C is a constant and w is the velocity with which the gases pass up the stove. This relationship holds only so long as the critical velocity of 2 metres per sec. is surpassed. With a velocity of 2–3 metres per sec., the transfer of heat is as great in 1 hour as in 3 hours with a velocity of 1 metre per sec. By increasing the height of the stove from 25 to 40 metres, the temperature of the hot blast is raised from 823° to 946° C., while the efficiency is raised from 51 to 66%. The replacement of the usual hexagonal brick with a circular aperture by an octagonal one which, when packed in the stove gives rectangular channels between the bricks as well as the circular ones within each brick, has resulted in a marked improvement. The time required to heat the stove is reduced to one-third and the increase in efficiency is 11%, while the temperature of the gas as it leaves the stove is reduced from 400° C. to 250° C.—F. C. Th.

Sulphur in iron and steel; Standard apparatus for the determination of — by the evolution method. H. B. Pulsifer, J. Ind. Eng. Chem., 1918, 10, 545–550.

The apparatus consists of a 500 c.c. conical flask provided with a side tube and a glass stopper through which passes the stem of a tapped 60 c.c.

funnel and the inlet and outlet tubes of a small spiral condenser arranged in the flask just below the stopper. The neck of the funnel carries a short length of glass tube forming a hollow ground-in stopper. Concentrated hydrochloric acid is used for the decomposition, and a current of hydrogen or carbon dioxide is used to remove the liberated hydrogen sulphide, the latter being collected in ammoniacal cadmium chloride solution and determined iodometrically. The condenser in the upper part of the flask maintains the hydrochloric acid at a maximum strength.—W. P. S.

Steel; Rapid determination of carbon in — by the barium carbonate titration method. J. R. Cain and L. C. Maxwell. J. Ind. Eng. Chem., 1918, 10, 520–522.

The method (see this J., 1911, 696, 966) may be simplified and rendered more rapid if carried out as follows. The furnace is heated at 1063° C. and 2 grms. of the sample is placed in the boat, filled with alundum sand, which has been in the hot furnace and then cooled to about 400° C.; the boat is immediately replaced in the furnace, and left for 1 min. with no oxygen passing. Oxygen is then admitted at the rate of 10 to 15 litres per minute, the outlet being constricted so that the rate of flow of gas at this end of the tube does not exceed 225 c.c. per minute. A roll of copper gauze is placed in the front end of the tube and heated at 200° to 260° C. Barium hydroxide solution in a Meyer absorption tube is used to absorb the carbon dioxide, and the barium carbonate formed is collected in a Buchner funnel, washed, and titrated. There should be vivid incandescence while the sample is burning and complete combustion of a 2-grm. sample is usually attained in 2 mins. Closed glass tubes may be inserted in the front end of the combustion tube to reduce the dead space. —W. P. S.

Steels; Effect of annealing on the electrical resistance of hardened carbon —. I. P. Parkhurst. J. Ind. Eng. Chem., 1918, 10, 515–518.

The total change in resistance increases with the carbon content of the steel; the change is rapid at the beginning of the annealing and becomes slower as the resistance decreases. Since the resistance of a steel changes with the hardness, resistance measurements are a fair indication of the varying rates at which hardened steels are softened by annealing at constant temperature. The larger part of the change occurs within a few minutes, but the change is not complete in 113 hrs. —W. P. S.

Electric furnace for annealing and forging of steel; Development of an —. W. S. Scott. Assoc. Iron and Steel Elect. Eng., Apr. 20, 1918. Chem. and Met. Eng., 1918, 19, 86–89.

EXPERIMENTS with resistor beds of granular graphite, coke, charcoal, and combinations of these showed that all were unsuitable for an electric forging furnace. Ashes or slag from commercially obtainable carbon cause clinkering of the bed with a rapid increase in resistance, and the great temperature difference in different parts of the resistor due to the electrical characteristics of carbon exceed the safe limits of refractory materials. Silicon carbide proved suitable when properly bonded, as the decomposition temperature is above 4000° F. (2200° C.) and blocks can be made of high tensile strength. With increase in temperature its conductivity increases rapidly, as it has a large negative temperature resistance coefficient. In a furnace with a radiating surface of

81 sq. ft., two resistor blocks, $9 \times 4\frac{1}{2} \times 2\frac{1}{2}$ in., were used, embedded in a refractory lining of crucible clay and graphite. Electrode chimneys or wells packed with granular graphite connected the resistors to external terminal connections. A forging temperature of 1800°F. (980°C.) was attained in two hours and the power at full load was 10 kilowatts (300 amp. at 33 volts), though for high-speed steel a preheating chamber is advisable. A uniform temperature together with a neutral atmosphere is obtained in all parts of the heating chamber, with complete control of the rate of heating, thereby eliminating many of the difficulties in reheating high-class steels.—C. A. K.

Gold precipitation from aurocyanide solution by charcoal. A. W. Allen. Met. and Chem. Eng., 1918, 18, 642–644.

PRECIPITATION by lump charcoal has never become a commercial proposition owing to the excessive quantity of charcoal necessary, but the Moore-Edmands process makes use of charcoal slime and effects a great improvement in this direction. A special form of extractor is used consisting of a small vacuum filter through which solution and charcoal pulp are pumped; fresh solution is added concurrently with the formation and maintenance of the charcoal cake. The extractors are worked in series, so that one containing nearly exhausted charcoal receives the richest solution. When finally exhausted the charcoal is washed, dried, and incinerated in braziers and the ash is smelted to recover the gold. Charcoals from different woods show widely differing precipitating powers, and the fineness of grinding is also an important factor. The principal drawback appears to be the amount of material to be smelted, though the actual operation entails no special difficulties. Edmands (this J., 1918, 183 A) gives the percentage of gold in the calcined ash as from 10 to 14%, and Walton (Rept. Dept. Mines, W. Australia, 1916) states that 1 ton of charcoal will precipitate 770 oz. of gold with production of about 6 cwts. of ash. Various theories have been brought forward to account for the action, e.g., occluded oxygen, electro-deposition, carbon monoxide, but it is thought that simple adsorption of aurocyanide (KAu(CN)_2) has the most evidence in support.—C. A. K.

Plating and refining baths; Rôle of complex salts as electrolytes in —. R. S. Dean and M. Y. Chang. Chem. and Met. Eng., 1918, 19, 83–85.

It has long been known that smoother and more adherent deposits of a metal are produced during electroplating from complex salts than from simple salts at equivalent concentrations, and experiments made on simple salts favour the theory previously proposed by Bancroft (J. Phys. Chem., 1905, 9, 290; see also this J., 1904, 1098) that the crystalline character of a deposit decreases with decreasing concentration of the ion being discharged, i.e., with increasing potential difference between the deposit and the bath. Whether this conclusion can be extended to solutions containing so little silver ion as the complex cyanides cannot be definitely stated. Experimenting on well agitated suspensions of silver oxide, chromate, chloride, thiocyanate, and sulphide, concentrations of the silver ion comparable with that of the cyanide solution were maintained. A deposit was obtained from the oxide suspension, but not from the less soluble salts. The deposition of silver from complex cyanide solutions is due to the discharge of potassium ion, and is secondary. The necessary conditions under which a complex solution will give an amorphous or a smooth deposit are that another metal with a lower solution-tension than

the one being deposited is present, and that a sufficiently complex salt is present that the concentration of the ion being deposited will be so low that its discharge voltage will be above that of the secondary metal.—C. A. K.

Copper minerals in partly oxidised ores; Determination of —. F. Cremer. Met. and Chem. Eng., 1918, 18, 644–646.

It is customary to determine the copper content of an ore in two forms, e.g., sulphide copper and "oxide" copper. The usual method for the determination of oxide copper by extraction with a 5% solution of sulphuric acid, when tried on an oxidised ore containing about 20% enprite and 10% chrysocolla resulted in some metallic copper from the cuprite being left undissolved, so that this, together with all native copper, would appear as sulphide copper. Again, few samples were found which did not contain metallic iron and by deposition of copper the error would be further increased. Phosphoric acid in a solution of ammonium chloride is suggested as a reagent; satisfactory results are obtained if the sample is finely ground before treatment. One gram of the sample is boiled gently with 20 c.c. of a 15% solution of phosphoric acid and an equal volume of a 20% solution of ammonium chloride. When cooled somewhat a small amount of freshly burnt lime and 25 c.c. of concentrated ammonia solution are added, and the flask is well shaken. After filtering, the ammoniacal copper solution is titrated in the ordinary way with cyanide solution. A second extraction is advisable in the case of high-grade oxide ores (say 30%).—C. A. K.

Aluminium and aluminium alloys; Chemistry of —. J. G. A. Rhodin. Faraday Soc., July 23, 1918. [Advance proof.] 12 pages.

The specific gravity of copper-zinc-aluminium alloys containing copper and zinc in equal amounts increases as the aluminium content is reduced. An alloy with 96.2% Al has sp. gr. 2.767 and one with 76.9% Al, 3.101. At about 76% Al a point of inflection occurs, the increase of density being then somewhat more rapid; an alloy with 62.6% Al has sp. gr. 3.519. Above 90% Al the sp. gr. falls rapidly. Porosity of the samples or the presence of heavy constituents, such as nitrides, may result in abnormal densities. The specific gravity is markedly influenced by the oxide which the metal can retain in solution. Virgin aluminium or its copper or copper-zinc alloy may normally contain $1\frac{1}{2}\%$ or so of oxide calculated as Al_2O_3 . "Burnt" samples may, as a result of repeated remeltings, contain 9% or more. The following method is given for determining the metallic aluminium directly:—The metal is treated with 10% sodium hydroxide solution and filtered, the undissolved residue containing the oxide present. A part of the filtrate is evaporated with strong hydrochloric acid to dryness, all free acid being removed by heating on a water-bath for at least 1 hour more. The residue is redissolved, sodium carbonate and barium chloride solutions are added, the precipitate is filtered off, washed, and redissolved in hydrochloric acid. The solution is heated to remove all carbon dioxide, and aluminium hydroxide precipitated with ammonia in the presence of ammonium chloride at 90°C. The precipitate is washed with a 5% ammonium nitrate solution, again dissolved in hydrochloric acid, the solution evaporated to dryness, and the residue kept at 100°C. for 2 hours. After removing the silica, the aluminium hydroxide is re-precipitated, filtered off, and washed. The residue insoluble in 10%

sodium hydroxide is dissolved in the minimum quantity of nitric acid, and the copper precipitated with hydrogen sulphide. The filtrate is concentrated, oxidised with bromine, and iron and aluminium hydroxides precipitated. The iron is determined by fusion with potassium bisulphate, reduction with zinc, and titration with permanganate. It is believed that when burnt in air, e.g., by heating the powdered metal in an open crucible, aluminium is converted into Al_2O_3 , which is soluble in the unoxidised metal. The existence of an oxide lower than Al_2O_3 is strongly suggested by the fact that an energetic "thermit" reaction can be induced between alumina and the metal, a grey powder being formed which is insoluble in a 10% sodium hydroxide solution and slowly soluble in nitric acid. The existence of an oxide Al_2O is unconfirmed, the substance having this composition being believed to be a solution of Al_2O_3 in aluminium. The specific heat of commercial aluminium of 98.6% purity between 20° C. and 100° C. is 0.2081, of an alloy of 90% Al with 10% Cu or Zn 0.1918, and of 80% Al and 20% Zn 0.1844.—F. C. Th.

Chromium; Passivity of —. A. H. W. Aten. Proc. K. Akad. Wetensch. Amsterdam, 1918, 20, 1119–1134.

When electrolytic chromium in contact with a solution of chromous sulphate is anodically polarised by the passage of a sufficiently strong current, the metal assumes the potential which is characteristic of the passive condition. When the current is stopped, the metal becomes active and its potential is more negative than before polarisation. The activity of the metal after anodic polarisation increases with the strength of the polarising current. Chromium, prepared by Goldschmidt's process, which has been activated by treatment with molten zinc chloride or a mixture of sodium and potassium chlorides, does not readily assume the passive condition when subjected to anodic polarisation in a solution of potassium chloride. The resistance to passivation is greater when the strength of the polarising current is slowly increased, than when this is increased rapidly. If the metal has been previously subjected to anodic polarisation, its resisting power is reduced. If the chromium has been made passive by anodic polarisation, the active condition is restored at once when the solution in contact with the metal is heated. The activity remains on cooling, even when the polarising current is continued, provided that the strength of the current is not too great. (See also J. Chem. Soc., Sept., 1918.)—H. M. D.

[Aluminium and chromium] carbides. O. Ruff. Z. Elektrochem., 1918, 24, 157–162.

ALUMINIUM carbide (Al_4C_3) sublimes at temperatures up to 2200° C. without melting and with some decomposition. The melting point of aluminium carbide lies higher than this. At 2200° C. aluminium carbide is in equilibrium with graphite, molten aluminium saturated with graphite, and vapour. The corresponding equilibrium mixture of chromium carbide, chromium, and graphite boils at 2270° C., the vapour consisting entirely of chromium. Between 2250° and 2050° C. the melt consists of Cr_3C_2 . Other carbides shown to be formed are Cr_2C_2 and Cr_3C_2 .—J. F. S.

"Stellite" [cobalt-chromium alloy]. L. Guillet and H. Godfroid. Rev. Mét., 1918, 15, 339–346.

"STELLITE" (this J., 1915, 1058) is a complex alloy of carbon, cobalt, chromium, tungsten, and, at times, molybdenum, etc., used for tools. The Brinell hardness in the cold is 495, which falls to 332 at 800° C. A good high-speed steel had a hard-

ness of 652 at ordinary temperatures, which had fallen to 112 at 800° C. Reheating "stellite" to temperatures up to 800° C. does not affect the hardness after cooling again. The microstructure in the cast condition shows the typical dendritic pattern which is not modified by reheating the material to 1150° C. and quenching it. When heated for 6 hours at 1000° C., the dendritic structure is obliterated. The following analyses illustrate the variations which are found in the composition of the alloy:—

Fe	C	Si	Mn	S	P	Co	V	Cr	W	Mo
10.06	1.79	0.78	0.72	—	—	34.6	1.0	26.4	12.7	9.4
—	1.48	0.17	—	0.01	traces	55.6	—	33.6	9.2	—

In the lathe tools made of "stellite" act at least as well as most of the high-speed steels on the market, at any rate on the softer materials; it is, however, somewhat uneven and the results obtained are not uniform.—F. C. Th.

Sulphide precipitation of group 2a metals. J. Shibko. Chem. News, 1918, 117, 253.

In the analysis of a brass or bronze the amount of copper found, even when the tin and the lead had been previously removed, was always slightly higher with ammonium sulphide as precipitant than with hydrogen sulphide, the solution being kept slightly acid. The error is due to small quantities of zinc brought down with the copper. A 60:40 brass, after removal of tin and lead, gave with hydrogen sulphide, Cu 59.86, Zn 0.0, with ammonium sulphide, Cu 60.12, Zn 0.25%. (See also J. Chem. Soc., Sept., 1918.)—C. S.

PATENTS.

Blast furnaces; Production of ammonium chloride during the working of —. A. Riedel, Koessern, Saxony. Eng. Pat. 102,146, Oct. 28, 1916. (Appl. No. 15,385 of 1916.) Under Int. Conv., Nov. 8, 1915.

In the zone of the blast furnace in which ammonia may be produced (500°–900° C.) no water vapour is present to aid this formation, all materials in normal working having been thoroughly dried in the upper part of the furnace. A uniform supply of water vapour is obtained by the introduction of a highly hydrated chloride with the furnace charge. The salt should be one which only parts with its water of crystallisation at a temperature at which ammonia is formed. The chlor-ion possesses the property of protecting ammonia from dissociation at even higher temperatures than water vapour does, and the conversion of fixed nitrogen into free nitrogen is restricted. Of the chlorides available, calcium chloride offers special advantages as the lime produced allows of a diminution of the normal quantity of lime in the blast-furnace charge.

Steel; Manufacture of —. H. A. Greaves and H. Etebells, Sheffield. Eng. Pat. 117,286, June 8, 1917. (Appl. No. 8175 of 1917.)

STEELS containing from 2 to 15% Mn and not more than 0.40% C may be made in the electric furnace

by adding ferromanganese to the liquid bath of metal and oxidising the excess carbon by manganese oxides, by adding previously refined ferromanganese, or by adding manganese ore, together with finely divided carbon, to the slag covering the steel. In plain carbon steels the addition produces metal from which plates with a very smooth surface, suitable for ship plates, may be obtained, and also tough, non-magnetic material for electrical machinery. In alloy steels a substitution of the cheaper manganese for the special elements produces economies and provides new special steels for armour and armour-piercing shells.—F. C. Th.

Zinc-bearing materials; Refining metallic — by the electrolytic process. Electrolytic Zinc Co., Inc., New York, Assignees of C. H. Aldrich and J. K. Bryan, Colgate, Md., U.S.A. Eng. Pat. 168,312, July 12, 1917. (Appl. No. 16,073 of 1917.) Under Int. Conv., July 26, 1916.

ZINC-BEARING minerals are refined electrolytically by the use of an acid electrolyte, containing from 0.1 to 0.5% of free acid, at about 40° C. or lower. The anode slimes are maintained substantially in contact with the anode, by means of a bag or the like surrounding the latter, so as to keep the more electro-negative metals, such as cadmium, from the disintegrated anode in contact with the excess of zinc in the anode, and thus prevent solution of the more electro-negative metal. If cadmium passes into the solution, it may be removed by passing the electrolyte through a number of tanks in series, provided with insoluble anodes, and after removal of the cadmium the electrolyte is returned to the main circuit.—B. N.

Separating metals [lead and zinc] from their ores; Process for —. A. L. J. Queneau, Newcastle-on-Tyne. Eng. Pat. 116,943, July 4, 1917. (Appl. No. 9674 of 1917.)

THE CRUSHED ore containing lead and zinc sulphides is mixed with excess of molten chloride of zinc and sodium (60% $ZnCl_2$ and 40% $NaCl$). Metallic zinc is then added to the hot mass to the extent of one-third by weight of the lead present, and the lead bullion separated and leached with water to remove the chlorides and the zinc sulphide formed. A flotation process allows the latter to be separated in a form which will yield a very high-grade zinc.

—F. C. Th.

Crucible furnaces. H. T. Lancey, Southampton. Eng. Pat. 116,916, July 5, 1917. (Appl. No. 9756 of 1917.)

To facilitate the slagging out of crucible furnaces of the tilting type, the bottom of the furnace is made as a pair of concave doors hinged to the furnace wall or fastened on by cotters. These doors can be opened and slag readily removed. To prevent spilled metal, etc., from corroding the iron, this is covered with a refractory lining of firebrick, etc. Loose trays may be inserted into the furnace above the doors and removed and replaced by new ones when full of slag.—F. C. Th.

Crucible furnaces; Tilting —. J. Gannt, D. Brookfield, and J. Tylor and Sons, Ltd., London. Eng. Pat. 117,054, Sept. 27, 1917. (Appl. No. 5152 of 1918.)

CRUCIBLE furnaces of the pattern described in Eng. Pats. 114,681 and 115,222 (this J., 1918, 308 A, 426 A) are mounted on an axis and tilted by means of a chain or wire rope attached to a winding drum. A balance weight may also be used to facilitate the operation.—C. A. K.

Crucible furnaces for melting metals. T. W. Aitken, Luton. Eng. Pat. 117,180, Sept. 17, 1917. (Appl. No. 13,306 of 1917.)

GREATER protection is afforded to the hearths of crucible furnaces, particularly of the type described in Eng. Pat. 107,468 of 1916 (this J., 1917, 967), by covering the floor of the furnace with a layer of sand, and by the provision of front and back doors above the sand covering, or of a tapping hole at this level.—C. A. K.

Furnace rakes for mechanical roasting furnaces. E. E. Brand, Helsingborg, Sweden. Eng. Pat. 116,974, Sept. 1, 1917. (Appl. No. 12,592 of 1917.)

THE blades of the rakes are inserted directly in longitudinal grooves in the radial arms fixed to a central vertical rotary shaft. The blade, which may be plane, bent, or curved, forms an obtuse angle with the furnace bottom and is also inclined in relation to the longitudinal direction of the supporting arm.—F. C. Th.

Heat treatment of metals; Gas heated and similar furnaces for —. C. R. Inman, Sheffield. Eng. Pat. 117,301, July 12, 1917. (Appl. No. 10,064 of 1917.)

EXTENDING longitudinally below the floor of the furnace is a combustion chamber into which nozzles for the supply of a mixture of gas and air pass. These nozzles are fitted with flanges below the floor of the chamber to prevent access of air and may be removed for inspection or cleaning. The hot gases from the combustion chamber pass up side flues into the furnace and escape through holes in the centre of the arched roof into a clear space above the furnace which they heat up before passing to the chimney. The heating is claimed to be rapid and economical, and since all the openings can be readily closed, the furnace can retain its heat for a long time.—F. C. Th.

Waste metal; Apparatus for recovery of —. G. W. Wardle, Birmingham. Eng. Pat. 117,321, July 31, 1917. (Appl. No. 10,990 of 1917.)

WHEN pouring aluminium or other metal covered with slag or dross, the metal remaining in the latter at the end of pouring may be caused to collect and separate from the impurities by the action of superheated steam at 300° F. (150° C.). The best means for doing this is to pour the dross and metal downwards through a hollow cone formed by superheated steam issuing from a series of holes in the under side of a circular pipe, the holes being directed inwards.—F. C. Th.

Metal; Apparatus for extracting — from ores. J. N. Lewis, Assignor to W. L. Wilson, Detroit, Mich. U.S. Pat. 1,265,459, May 7, 1918. Date of appl., Oct. 28, 1916. Renewed Mar. 8, 1918.

A CONTAINER for the solvent and ore is provided with a combined filtering and precipitating unit, fitted as a removable portion of the wall. Fibrous material forms the filtering medium and this is clamped to a porous container for the precipitating agent.—C. A. K.

Annealing and other furnaces; Means for feeding goods into and removing goods from —. Gibbons Bros., Ltd., and M. van Marle, Lower Gornal, Staffs. Eng. Pat. 116,949. (Appl. Nos. 9924, July 10, 1917, and 2283, Feb. 8, 1918.)

Crucible furnaces and the like; Operating mechanism of tilting —. Alldays and Onions Pneumatic Engineering Co., Ltd., A. Nicholson, and H. Hodkinson, Birmingham. Eng. Pat. 117,212, Nov. 29, 1917. (Appl. No. 17,660 of 1917.)

Distilling ores and metal-bearing products; Apparatus for —. D. B. Jones, Chicago, Assignee of C. H. Fulton, St. Louis, U.S.A. Eng. Pat. 111,835, Aug. 10, 1917. (Appl. No. 11,497 of 1917.) Under Int. Conv., Dec. 7, 1916.

XII.—FATS; OILS; WAXES.

Fatty oils of Sambucus racemosa, L. H. J. Zellner. Monatsh. Chem., 1918, 39, 87–94.

THE European elder, *Sambucus racemosa, L.*, and the North American *Sambucus racemosa, var. arborescens*, although very similar, exhibit distinct but slight differences in nature; this probably accounts for the difference between the characteristics of the oil from the flesh of the red berries of these varieties (Zellner, this J., 1903, 101, and Byers and Hopkins, this J., 1902, 1238, respectively). The oil from the former when kept for 15 years in a stoppered flask undergoes marked alteration with increase in the proportion of free acid and decrease in the iodine value. The elder seeds also yield an oil, of sp. gr. 0.934 at 15° C., $[\alpha]_D^{20} = +1.485$, saponification value 190.8, and iodine value (Hibb), 162.0; in its drying properties and other characteristics this oil resembles linseed oil.—D. F. T.

Cholesterol and the higher fatty acids; Nephelometric values of —. F. A. Csonka. J. Biol. Chem., 1918, 34, 577–582.

THE turbidities produced by the addition of acid to solutions of cholesterol and various soaps differ in intensity and stability. Estimations of fat by nephelometric methods are therefore open to error unless the nature of the fat is known and allowed for in calculating the results. (See also J. Chem. Soc., Sept., 1918.)—H. W. B.

Dubrisay's method of testing [viscosity of] lubricating oils. Nicolardot and Masson. See II.

PATENTS.

Hydrogenation; Process of —. C. Ellis, Montclair, N.J. U.S. Pat. 1,266,782, May 21, 1918. Date of appl., Nov. 23, 1914.

THE material to be hydrogenated, together with hydrogen, is subjected to the action of a catalytic body comprising nickel and silica, both in a non-abrasive, e.g. colloidal, condition, and associated with another metal having catalytic properties, e.g., a metal of the palladium group.—A. de W.

Oils and the like; Method of extracting —. R. Wells, Homer, N.Y., Assignor to Cobwell Corporation, Cleveland, Ohio. U.S. Pat. 1,267,611, May 28, 1918. Date of appl. Mar. 11, 1915. Renewed Oct. 22, 1917.

TO extract oils or the like from a material also containing water, the material, in a relatively thin layer, is immersed in a water-insoluble solvent having a higher boiling point than water. Means are provided for moving an arm underneath the layer of material in order to impart an undulatory

movement thereto without bodily moving the same, whilst simultaneously stirring its upper surface. The temperature of the mass is then raised to the joint boiling point of the solvent and the water and as evaporation of both proceed, more solvent is added. After expelling water from the material in this way, the oil or the like material is extracted by means of a solvent of lower boiling point than water.—A. de W.

Catalysts [for hydrogenation of oils]; Preparation of — J. Dewar, London, and A. Liebmann, Weybridge, Assignors to The Procter and Gamble Co., Cincinnati, Ohio. U.S. Pat. 1,268,692, June 4, 1918. Date of appl., June 2, 1914.

SEE Eng. Pat. 12,981 of 1913; this J., 1914, 797.

Method of determining the viscosity of fluids. Eng. Pat. 117,234. See XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Constituents of — I. Siarensinol from Siamese gum benzoin. A. Zinke and H. Lieb. Monatsh. Chem., 1918, 39, 95–106.

On treatment with hot sodium hydroxide solution Siamese gum benzoin yields the sodium derivative, $C_{30}H_{47}O_2Na$, SH_2O , $[\alpha]_D^{21} = +34.97^\circ$, of siarensinol, from which siarensinol, $C_{30}H_{48}O_2$, $[\alpha]_D^{22} = +27.31^\circ$ (in methyl alcohol) is liberated by hydrochloric acid, this substance being probably identical with the benzoresinol of Lüdy (this J., 1893, 946; compare Reinitzer, this J., 1915, 681). With acetic acid siarensinol yields an additive compound, $C_{30}H_{48}O_4$, $C_2H_4O_2$, crystallising in prisms, m.pt. 288° – 281.5° C., whilst the sodium derivative reacts with benzoyl chloride giving a benzoyl derivative, $C_{37}H_{52}O_4$, crystallising in needles, m.pt. 182° – 183° C., $[\alpha]_D^{20} = +30.0^\circ$ in ethyl alcohol.—D. F. T.

PATENTS.

[Titanium dioxide] pigments; Manufacture of white or light coloured — B. E. D. Kilburn, London. From Det Norske Aktieselskab for Elektrokemisk Industri, Norsk Industri-Hypotekbank, Christiania. Eng. Pat. 110,535, May 8, 1917. (Appl. No. 7214 of 1917.)

A WHITE pigment of high opacity combined with an absence of externally crystalline outline in the composing particles such as is possessed by pulverised titanium dioxide crystals of high refractive index, e.g., rutile, although of internally crystalline structure, is obtained by converting an amorphous titanium oxygen compound, such as titanium dioxide or titanic acid hydrate, into an internally crystalline titanium dioxide by means of heat. A halogen compound may be added to act as a catalyst of the crystallisation process. The progress of the crystallisation on heating may be determined by observing the increasing double refraction of the particles under the microscope between crossed nicols. The titanium pigment may also if desired be associated with barium sulphate and/or calcium sulphate.—A. de W.

Carbon-pigment base and process of making same. D. J. Ogilvy, Cincinnati, Ohio. U.S. Pat. 1,268,142, June 4, 1918. Date of appl., July 21, 1916.

CARBON pigments for printing inks, paints, or the like are obtained by impinging a carbonaceous flame against a cool high "fire test" oily surface until the oil is charged with carbon.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Sulphur in soft rubber compounds; Determination of free — H. S. Upton. J. Ind. Eng. Chem., 1918, 10, 518–520.

Two grms. of the rubber compound is extracted with acetone until all the free sulphur is dissolved, the acetone solution is then evaporated, and the residue dried at 100° C. This residue is boiled for 1 hour with 50 c.c. of 5% alcoholic potassium hydroxide solution, then cooled, and treated with 50 c.c. of ammonium zinc chloride solution (10 grms. of zinc oxide dissolved in hydrochloric acid, neutralised with ammonia, 50 c.c. of ammonia of sp. gr. 0.9 added in excess, and the solution diluted to 1 litre), neutralised with acetic acid, 3 c.c. of the latter is added in excess, the mixture is diluted to 200 c.c., and titrated with N/20 iodine solution; the titration gives the quantity of sulphur which has been converted into thiosulphate. The portion of sulphur converted into sulphide is found by treating the titrated solution with ammonia, then acidifying with hydrochloric acid, and again titrating the mixture with iodine solution. The sum of the two titrations is a measure of the free sulphur originally present. A correction for other reducing substances is found by treating similarly a rubber compound of the same character but containing no free sulphur.—W. P. S.

PATENTS.

Rubber; Compounds for use in lieu of — J. Flint, Rushcutters Bay, N.S.W. Eng. Pat. 105,912, Apr. 10, 1917. (Appl. No. 5012 of 1917.) Under Int. Conv., Mar. 21, 1916.

Recovery by condensation of volatilised solvents. Eng. Pat. 116,590. See I.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin; Influence of neutral salts, bases, and acids on the precipitation of — by alcohol. J. Loeb. J. Biol. Chem., 1918, 34, 489–501. (Compare this J., 1918, 383 A, 384 A.)

GELATIN powder which has been treated with salt solution and, after washing, dissolved in water, is not reprecipitated by alcohol when the salt employed contains univalent anions and cations above M/128 concentration. For salts with divalent cations, the limiting concentration is M/256. The anion is without action. These and similar results are explained by the assumption that salts of gelatin with univalent cations are readily ionised, whilst those with divalent cation are less or not at all ionisable. The anion of the salt behaves as if it did not combine with the gelatin at all.—H. W. B.

PATENTS.

Glue or gelatin; Manufacture of substances capable of precipitating — J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 116,933, June 29, 1917. (Appl. No. 9380 of 1917.)

WATER-SOLUBLE products capable of precipitating gelatin and having valuable tanning properties are prepared by treating with sulphonating agents a naphthylsulphone (dinaphthylsulphone or its derivatives containing at least one naphthalene residue free from hydroxyl) which can be produced from naphthalene by suitable treatment with sulphuric

acid. The products so obtained may be condensed with formaldehyde, when useful tanning substances are produced, or skins treated with formaldehyde may be tanned by the original substances.—F. C. T.

Tanning, and manufacture of agents to be used therein. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 116,934, June 29, 1917. (Appl. No. 9381 of 1917.)

EASILY soluble condensation products capable of tanning leather are obtained by heating together a phenolsulphonic acid and a sulphonated hydrocarbon such as benzenesulphonic acid or "sulphonated rock oil." For example, the product obtained by heating Caucasian "naphtha" with sulphuric acid at 100° C., is mixed with phenolsulphonic acid and heated for 20 hours at 130° C. The product is diluted with water, filtered, and concentrated.—F. C. T.

Tanning. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 116,935, June 29, 1917. (Appl. No. 9382 of 1917.)

HIDES or skins may be tanned by aqueous solutions of sulphonic acids of aromatic hydrocarbons, or sulphonated derivatives of these, not containing hydroxyl groups, e.g., sulphonic acids of anthracene, phenanthrene, etc., and their derivatives. Such sulphonic acids used singly or in mixture can be used for tanning either with or without the addition of natural tanning materials. The dark colour produced by some natural tanning materials can be cleared by the use of sulphonic acids.

—F. C. T.

Hides, skins, and leather; Machines for treating —. J. W. H. Hall, Leeds. Eng. Pat. 117,358, Oct. 9, 1917. (Appl. No. 14,621 of 1917.)

Process of making fertiliser [from leather]. U.S. Pat. 1,268,683. See XVI.

XVI.—SOILS; FERTILISERS.

Protozoa in the soil; Method for the counting of certain —. A. Itano and G. B. Ray. Soil Sci., 1918, 5, 303–310.

A WHIPPLE cell (compare "Microscopy of Drinking Water," 1914, p. 34) was thoroughly cleaned with water and then with xylene. The bottom of it was covered by means of a platinum loop with a thin layer of phenolsulphonaphthalein solution, and when this had dried, the culture, previously diluted with a 4% gelatin solution, adjusted to pH 8, was run in as described by Whipple (*loc. cit.*). The number of protozoa was then counted and from these data the total number of organisms per c.c. of suspension was calculated. The soil culture was prepared by adding 5 grms. of soil to 100 c.c. of a mannitol solution, gently shaking, and allowing to stand at the ordinary temperature for 2 or 3 weeks. The results indicate that the use of a vital stain aids materially in defining the organism. The results are seriously affected when the soil is allowed to settle, but rapid motion is inhibited by the use of the semi-solid diluent. The probable error seems to vary inversely with the size of the organisms and directly with the magnification.

—W. G.

Sulphofication in relation to nitrogen transformations [in soils]. J. W. Ames and T. E. Richmond. Soil Sci., 1918, 3, 311–321.

OXIDATION of free sulphur in soils devoid of bases depresses the activities of nitrifying organisms, and even when calcium carbonate is added in excess of the lime requirement of the soil the yield of nitric nitrogen from casein is considerably decreased by oxidation of added sulphur. The depression increases as the basidity decreases. There is an increase of ammonia as the yield of nitrates decreases when sulphur is oxidised, this being due probably to the deficiency of calcium carbonate necessary for the neutralisation of the sulphuric acid formed. The ammonia formed neutralises the sulphuric acid and remains as ammonium sulphate.

—W. G.

Sulphur: Oxidation of — by micro-organisms in its relation to the availability of phosphates. H. C. McLean. Soil Sci., 1918, 5, 251–290.

THE most economical combination for the production of available phosphoric acid from rock phosphate appears to be 100 parts of soil, 120 parts of sulphur, and 400 parts of rock phosphate, although an appreciable amount of phosphoric acid is rendered available even if the soil is omitted. Of the different "floats" tried, Florida soft rock phosphate gave the best yield of available phosphoric acid. Fineness of grinding is an advantage provided that it is not carried to such an extent as to inhibit biological activities owing to lack of aeration. Micro-organisms are influential in the oxidation of sulphur and the rendering available of the phosphorus in rock phosphate, and as these organisms are apparently mainly aerobic, aeration is of great importance. Of the various catalysts tried, the sulphates of ammonium, calcium, magnesium, and zinc exerted no influence on the process, whilst sodium nitrate, potassium iodide, and copper sulphate exerted a depressing action on the organisms. When present in small amounts (0.4 lb. per ton) in composts, ferrous sulphate and aluminium sulphate or a mixture of the two, exerted a marked stimulating action on sulphur oxidation processes and on the rendering available of the phosphorus. The presence of organic substances such as peat, fresh horse manure, old composted manure, or peptone is not desirable, and calcium carbonate brings about a decrease in available phosphorus when added to a sulphur-rock phosphate-soil compost.—W. G.

Nitrogen in nitrate of soda, ammonium sulphate, dried blood, and farm manures; Twenty years' work on the availability of —. J. G. Lipman and A. W. Blair. Soil Sci., 1918, 5, 291–301.

OVER a period of twenty years in a five-course rotation sodium nitrate at the rate of 320 lb. per acre per annum gave better crop yields than an equivalent amount of either ammonium sulphate or dried blood. During the first ten years the two latter fertilisers gave results about on a par with those from the former, but after that they showed a considerable falling off. The average nitrogen recovery in the crops over the twenty years from each fertiliser was: sodium nitrate, 62.42%; ammonium sulphate, 47.48%; dried blood, 38.69%; cow manure, 32.69%. Cow manure at the rate of 16 tons per acre gave somewhat larger crop yields than sodium nitrate at the rate of 320 lb. per acre, but the increased yields were not sufficient to justify the increase in the cost of nitrogen.—W. G.

Liquid manure; Decomposition and preservation of —. E. Blanck. Landw. Versuchs-Stat., 1918, 91, 253–269, 271–290, 309–343.

Liquid manure (urine) decomposes rapidly when applied to soils, the loss of nitrogen depending on the rate of evaporation of the liquid and on bacterial action. Treatment of the liquid manure with sulphuric acid prevents loss of nitrogen in so far that it fixes, up to a certain limit, the ammonia formed. Formaldehyde preserves the urine, but its use is not recommended, as it interferes with plant growth.—W. P. S.

Dicyanodiamide; Constitution of —. W. J. Hale and F. C. Vibrans. J. Amer. Chem. Soc., 1918, 40, 1046–1063.

From the facts that (1) three-fourths of the nitrogen in dicyanodiamide can be expelled by 20% sodium hypochlorite solution, (2) nitrous acid, acting on a solution of dicyanodiamide in aqueous acetic or phosphoric acid at the boiling point, expels from one to four atoms of nitrogen according to the concentration of the acid, (3) the condensation of dicyanodiamide and acetylacetone by aqueous sodium hydroxide yields 2-imino-1-cyano-4,6-dimethyl-1,2-dihydropyrimidine, $C_8H_{10}N_4$, colourless needles, m.pt. 225° C., the authors are of opinion that the constitution of dicyanodiamide must be represented by the cyanoguanidine structure, $NH_2C(C \equiv N)NHCN$, originally proposed by Bamberger (Ber., 1883, 16, 1074). (See also J. Chem. Soc., 1918, i., 350.)—C. S.

Superphosphate; Use of nitre-cake in the manufacture of —. 54th Annual Report on Alkali Works for 1917 by the Chief Inspector, 19–20.

A SUCCESSFUL process is in use for the manufacture of superphosphate from Tunisian phosphate and nitre-cake. The nitre-cake is ground in an ordinary disintegrator and if ground phosphate is gradually mixed with it during the grinding clogging of the machine is obviated. It has been found necessary to add to the mixing about 10% of hot water more than is present when sulphuric acid of 118° Tw. (sp. gr. 1.59) is used. Comparatively little heating or evolution of gas occurs. Analysis of the product (after two weeks) gave 16.36% of water-soluble phosphate.—C. A. K.

Seeds; Prejudicial effects of treatment with formalin upon the germination of —. L. Kiessling. J. Landw., 1918, 66, 7–51.

It has been customary to treat seed corn with formaldehyde solutions to get rid of bunt in oats and rust in wheat, and this treatment has been observed to influence germination. Culture and germination experiments extending over two years showed that the immersion of seed in a solution containing 0.1 per 1000 of formaldehyde for a quarter of an hour retarded the onset of germination and also the total time of germination, although the number of plants obtained was about the same as from untreated seed. When artificially damaged seeds were submitted to treatment, they appeared to undergo no greater injury than sound seeds. Some of the injurious effects were due to the presence of impurities, such as methyl alcohol, in the solutions used, which are customarily prepared from formalin, and it was proved that it would be better to employ pure solutions prepared from paraformaldehyde. The use of formalin to protect seeds against mildew is not to be recommended, unless a pure solution of formaldehyde is used or part of the formalin is replaced by another fungicide.—J. H. J.

Determination of ammonia in urine, serum, etc. Wiessmann. See XXIII.

PATENTS.

Fertiliser purposes; Process of treating organic matter for —. A. J. Grinberg, New York, and B. Field, Plymouth, Mass. U.S. Pat. 1,268,563, June 4, 1918. Date of appl., Apr. 27, 1917.

ORGANIC matter is treated with acid producing and denitrifying bacteria, with or without the addition of a phosphate compound and a potash compound, and the whole allowed to "work" by growth of bacteria and then dried.—W. G.

Fertiliser; Process of making — [from leather]. D. E. Clark, Lynn, Mass. U.S. Pat. 1,268,683, June 4, 1918. Date of appl., July 18, 1917.

THE fertiliser is produced by treating leather with the liquor known as "dunder."—W. G.

Fertiliser. H. Blumenberg, jun., Oro Grande, Cal., Assignor to Golden State Portland Cement Co., Los Angeles, Cal. U.S. Pat. 1,270,688, June 25, 1918. Date of appl., Mar. 4, 1918.

THE fertiliser consists of calcium carbonate, 2 parts, and calcium sulphate, 1 part.—W. G.

Phosphate manure; New soluble and assimilable — and process for making it. E. Stoppani, Bologna, and V. Volpato, Milan, Italy. U.S. Pat. 1,267,473, May 28, 1918. Date of appl., Oct. 5, 1916.

SEE Fr. Pat. 450,697 of 1916; this J., 1917, 152.

XVII.—SUGARS; STARCHES; GUMS.

Dextrose; Rate of production of colour in alkaline solutions of — and picrate. T. Addis and A. E. Shevsky. J. Biol. Chem., 1918, 35, 43–51.

THE results show that under the conditions described in most methods for the colorimetric estimation of dextrose by picrate and alkali, an increase in the concentration of dextrose does not lead to an exactly proportionate increase in colour. The most satisfactory conditions are found to be a concentration of 10% of sodium carbonate and the heating continued for 45 minutes at 100° C. in the presence of 0.8% of picric acid.—H. W. B.

Starch; Bulrushes as a source of —. L. Koffer. Z. Unters. Nahr. Genussm., 1918, 35, 266–272.

ATTENTION is directed to the high starch content of bulrush roots, the quantity present being about 46% of the dry substance. The powdered root has a characteristic appearance under the microscope and the starch grains are of two sizes, the larger being about 13 μ and the smaller 3.5 μ in diameter.—W. P. S.

Law of action of sucrase [invertase]. Colin and Chaudun. See XVIII.

PATENTS.

Sugar cane; Process for extracting sucrose from —. A. Adams, Kahuku, Hawaii. U.S. Pat. 1,265,582, May 7, 1918. Date of appl., Aug. 25, 1915.

THE cane, after passing through a crusher and shredder, is conveyed to a diffusion cell. The juice

from the shredder passes to a hulling tank and thence through a heater to the cell. The bagasse from the cell is conveyed to a mill and the juice from the latter can be returned to the hulling tank and diffusion cell.—J. H. L.

Bagasse; Method of Treating — for the recovery of its values. M. W. Marsden, Assignor to Sugar Cane By-Products Co., Philadelphia, Pa. U.S. Pat. 1,265,694, May 7, 1918. Date of appl. Nov. 11, 1915.

BAGASSE is reduced to a uniformly divided state and freed from all but about 10% of its natural moisture-content. The pith is then separated from the fibre and ground to a flour, which after being boiled with water and washed, is obtained in the form of a paste. This paste may be employed for the production of glucose.—J. H. L.

Glue or adhesive; Vegetable —. R. W. Tunnell, Philadelphia, Pa. U.S. Pat. 1,266,354, May 14, 1918. Date of appl. Nov. 9, 1917.

AN adhesive is formed from hydrolysed starch and zinc chloride, with or without an excess of caustic alkali; e.g., zinc chloride may be added to a viscid mixture of starch, water, and caustic alkali.

—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Barleys; Institute of Brewing method for the determination of the moisture-content of —. Committee of the Institute of Brewing. J. Inst. Brew., 1918, 24, 234.

The following standard method for determining moisture in barley has been adopted by the Institute. About 10 grms. of the well mixed sample is ground as finely as possible in a coffee mill previously rinsed with the same sample. 4–5 grms. is weighed out in a weighing bottle about 2 ins. in diameter and 1 in. high, provided with a cover, and this is then placed in a boiling water oven for 5 hours, the cover resting on the top of the oven meanwhile. After 5 hours, the vessel is covered, transferred to a desiccator and weighed as soon as cool. The percentage moisture-content is calculated to the nearest first decimal. The oven should contain nothing but barley samples, and these should be placed not on the shelf but on the floor of the oven, and not close to the door. The oven door must not be opened during the drying. The ventilator in the door must remain open and the orifice at the top of the oven kept free. To prevent furring, it is advisable to use distilled water for heating the oven. With each batch of barleys a determination should be made on a stock sample, as control. Careful adherence to the method should ensure agreement to within 0.5%.—J. H. L.

Barley; Determinations of acidity in — by titration in stages. A. Reichard. Z. ges. Brauw., 1918, 41, 57–60, 65–68, 75–77, 83–81, 89–90.

IN continuation of previous work (this J., 1917, 399), aqueous extracts of barley were made, under conditions excluding enzyme action, and titrated with alkali, first in presence of litmus and then in presence of phenolphthalein. The most satisfactory method of preventing enzymic action was found to consist in heating the ground barley with alcohol (cp. Lüers and Adler, this J., 1915, 1158), and evaporating off the latter, after which the material was digested with cold water for at least 3 hours, and titrated. With freshly harvested barley the acidity determined in presence of phenolphthalein was much greater than that determined

in presence of litmus, sometimes twice as great. During storage of the grain the former value gradually diminished and finally coincided with the latter. This diminution of the "phenolphthalein acidity" is attributed to the disappearance of amino-acids (acid towards phenolphthalein but not towards litmus), a change which, according to Schjörning (this J., 1906, 1109) and others, is characteristic of the process of "after-ripening" of barley. The identity of the "litmus acidity" and the "phenolphthalein acidity" might be regarded as a sign that barley is completely matured and ready for malting. In exceptional cases, however, barleys which do not conform with this analytical standard give good results on germination.—J. H. L.

Brewing material; Sudan durra as a —. L. Briant and H. Harman. J. Inst. Brew., 1918, 24, 209–214.

DURRA forms the staple food of the population of the Sudan and is the subject of a growing export trade. At the suggestion of the Imperial Institute, the authors had placed at their disposal 5–6 tons of the material for the purpose of investigating its suitability for brewing purposes. The composition of a sample of durra analysed at the Imperial Institute was as follows:—moisture 8.45%, proteins 13%, fat 3.30%, fibre 1.03%, ash 1.71%, carbohydrates (by difference) 72.45%; nutrient ratio 1:6.1; food units 113.3. With the collaboration of various manufacturers, large-scale experiments were made on the conversion of the material into malt, roasted grain, flaked products, and glucose. The results of the maltings were not promising, for although the product was moderately friable and possessed a fair diastatic power, it yielded only about one-third as much extract as barley malt. By roasting the grain, products were obtained having a satisfactory aroma and flavour, comparing favourably with those of roasted barley. Experimental brews for porter showed that 7 parts of roasted durra may replace 10 parts of roasted barley without interfering with the character of the beer. The malting of the grain before roasting is not recommended. Amber durra malt of fine flavour was prepared, but its yield of extract was very low. Satisfactory flaked products were prepared from durra without difficulty. Their appearance was not so attractive as that of flaked maize or rice, and the flakes, being rather brittle, would probably produce a considerable amount of dust during transport which might interfere with mash-tun drainage. In the flaking process about 15% of meal was produced. This contained about two-thirds of the oil in the durra seed, leaving only about 1.3% in the flakes; it would constitute an excellent cattle food. The whole of the starch in the durra appeared to be rendered available by flaking. The character of the extract was quite satisfactory, closely resembling that from flaked rice: 236 lb. yielded 94.4 lb. of extract, as compared with 100–102 lb. from flaked maize. Replacement of half the flaked maize (15%) by flaked durra, in the preparation of bitter beer or pale ale, led to no considerable defect in the products, and total replacement would have been quite practicable. Flaked durra might prove excellent for direct human consumption. Good brewing sugar, for use in the copper or as priming of the malto-dextrin type was prepared from durra.—J. H. L.

Hop extracts; Colour of — and the influence of the salts of water thereon. H. Krumhaar. Woch. Brau., 1918, 35, 25–27.

BREWERY WORTS made with waters rich in carbonates sometimes assume a reddish tint after

boiling with hops and cooling, and the tint becomes less pronounced in the course of fermentation. From the author's experiments it is concluded that, at the same concentration, calcium and magnesium bicarbonates are equally active in producing this coloration, that the normal carbonates do not produce it, and that it is due to combination of the bicarbonates with certain hop constituents.

—J. H. L.

Hop extracts; Coloration of —. A. Bau. Woch. Brau., 1918, 35, 73–74, 79–83, 90–92. (See preceding abstract.)

EXPERIMENTS in which water containing magnesium bicarbonate was boiled with hop extract, indicated that the reaction to which the colour is due is not instantaneous but requires about an hour's boiling, that the presence of air is necessary for the colour to develop, and that addition of gypsum in amounts corresponding with brewing practice does not prevent the coloration. In equimolecular concentrations calcium bicarbonate produces a less pronounced colour than magnesium bicarbonate; but sodium carbonate is about as active as the latter. Boiling of calcium bicarbonate solutions before addition of hop extract does not entirely prevent the coloration, and in the case of magnesium bicarbonate previous boiling has no effect.—J. H. L.

Beers; Attenuation of low gravity —. E. Schlichting. U.S. Master Brewers' Assoc. Brewers' J., 1918, 54, 249.

DISCUSSING the problem of brewing palatable and stable beer containing not more than 2.75% of alcohol, the author recommends that a product of the following composition should be aimed at:—alcohol, 2.5–2.6% by weight; acidity, 0.12–0.14%; real unfermented extract, 4.3–4.4%; original gravity, about 9.5% Balling; ratio of alcohol to real extract, 1:1.66–1:1.75; apparent degree of attenuation 61–68%; real degree of attenuation 52–54%. It is stated that such a product may be obtained by using 75% of malt and 25% of raw grain, holding the mash for an hour at 38° R. (47.5° C.) and carrying out conversion at 58° R. (72.5° C.), hopping at the usual rate (for lager beer) in proportion to the extract, and fermenting as completely as possible. Great importance is attached to the ratio of alcohol to extract: too high a proportion of the latter renders the beer insipid.—J. H. L.

Beer; Investigation of — for antineuritic and antiscorbutic potency. A. Harden and S. S. Zilva. J. Inst. Brew., 1918, 24, 197–208.

THE history of the subject of deficiency diseases and their prevention and remedy is sketched, and experiments are described, comprising feeding tests with pigeons, guinea-pigs, and monkeys, which indicate that beer and malt are destitute both of the antineuritic and the antiscorbutic substances; i.e., they have neither preventive nor curative action on polyneuritis or scurvy produced by defective diet.—J. H. L.

Oxalic acid in beer [urine, etc.]; Determination of —. A. Bau. Woch. Brau., 1918, 35, 31–33, 40–42, 45–47, 51–53, 57–59, 63–65, 70–71.

THE minute quantities of oxalates present in beers (cp. Will. this J., 1916, 191) may be precipitated by a reagent prepared by mixing 500 c.c. of 50% acetic acid containing 25 grms. of crystallised calcium chloride, with 500 c.c. of saturated sodium acetate solution (cp. Kreis and Paragiola, this J., 1916, 483). 400 c.c. of filtered beer is treated with 80 c.c. of the clear reagent, and left for 38–44 hours

at a temperature below 7° C. The deposited calcium oxalate may be identified microscopically, or determined quantitatively by filtering off, washing thoroughly with cold water, igniting, and estimating the lime by dissolving in N/10 hydrochloric acid and titrating back with N/10 sodium hydroxide in presence of methyl orange. A correction may be made for the oxalate remaining in the mother liquor and the washings, on the basis that the solubility of calcium oxalate in the former is 4.86 mgrms., and in the latter 6.6 mgrms., per litre. The method might be applied to other liquids, e.g., urine, which, like beer, do not contain tartaric acid, this being the only other acid besides oxalic acid precipitated under the prescribed conditions. The results obtained with beers of different types ranged from 8 to 34 mgrms. of calcium oxalate per litre. The oxalates in beer appear to be derived chiefly from the hops and to some extent from the malt; during fermentation the oxalate-content of the wort diminishes.—J. H. L.

Banana must; Alcoholic fermentation of —. R. Perratti and V. Riviera. Staz. Sperim. Agrar. Ital., 1917, 50, 433–450. Bull. Agric. Intell., 1918, 9, 610–612.

EARLIER work on the chemistry and bacteriology of the *Musa sapientum* banana is summarised. To obtain a must which will retain after fermentation the flavour of the fruit, the skins as well as the pulp must be extracted. From such a must the authors isolated four organisms: a *Saccharomyces* predominant in the fermented liquid and designated *Sacch. musae*, a bacterial form abundant in the liquid, a variety of *Oospora lactis*, and a *Mycoderma* form. Particulars of these organisms are given. From an experiment on the fermentation of an extract of skins and pulp, with *Sacch. musae*, it appears possible to produce from the banana, by adding sugar to the must, and perhaps purifying after the primary fermentation, a fermented liquid of good colour, slightly alcoholic, and of attractive qualities amongst which the agreeable aroma of the fruit holds first place.—J. H. L.

Alcohol; Production of — from algae. Kayser. Comptes rend. Acad. d'Agric., 1918, 4, 450–451. Bull. Agric. Intell., 1918, 9, 612–613.

Laminaria digitata, dried to a moisture content of 10%, was heated for $\frac{1}{2}$ –1 hour at 122° C., with water containing 3–6% of sulphuric acid. The cooled liquid, brought to a specific gravity of 0.1%, and sprinkled with brewers' yeast, fermented readily, especially after addition of nitrogenous material, and yielded 6 litres of alcohol per 100 lb. of dry algae. Higher yields might perhaps be obtained under industrial conditions, and the mineral matter in the vinasses might be utilised.—J. H. L.

Cognac kept in wooden barrels; Alteration of the alcohol content of —. A. Behre. Z. Unters. Nahr. Genussm., 1918, 35, 281–283.

ALTHOUGH considerable evaporation took place, the loss amounting to some 30%, when cognac was kept for 18 months in a wooden barrel, the alcoholic strength (40% by vol.) and the total solids remained almost constant: the alcohol-content tended to increase to the extent of about 1% per year.

—W. P. S.

Enzymes; Chemistry of —. H. von Euler. Z. Elektrochem., 1918, 24, 173–177.

THE inversion of sucrose by yeast is accompanied by an increase in the invertase to a maximum and an increase in the enzyme concentration according

to the equation $dx/dt = k(a-x)$, where a is the initial concentration of sucrose and x is the amount inverted after time t . In the hydrolysis of starch by the enzyme of *Mucor mucedo* the velocity of the enzyme formation is constant.—J. P. S.

Sucrase [invertase]; Law of action of —. H. Collin and A. Chaudun. *Comptes rend.*, 1918, 167, 208—210.

THE authors find that only at concentrations of sucrose not exceeding 2% does the inversion of sucrose by invertase obey Wilhelm's law $x = a(1 - e^{-kt})$, where a is the initial concentration of sucrose and x is the quantity of sucrose hydrolysed after time t .—W. G.

PATENTS.

Malt-drum; Rotary —. O. Gaebel, Breslau, Germany. Eng. Pat. 116,966, Aug. 14, 1917. (Appl. No. 11,671 of 1917.)

A rotary malt-drum has within it two screws or helical blades of about the same graduation, one right-handed and the other left-handed. One is mounted on the outside of a central perforated pipe (which serves to admit air), and the other on the inside of a co-axial perforated cylinder or pipe of somewhat smaller diameter than the drum itself. When the drum rotates the contents are mixed owing to the fact that the two screws drive the central and peripheral parts of the charge in opposite directions.—J. H. L.

Alcohol; Manufacture of — from grain in open vats with the employment of saccharifying *Mucors*. Soc. d'Exploit. des Proc. H. Boulard, Paris. Eng. Pat. 102,945, Dec. 7, 1916. (Appl. No. 17,596 of 1916.) Under Int. Conv., Dec. 28, 1915.

COOKED grain mashies are saccharified and fermented in open vats by means of a robust *Mucor* such as *Mucor Boulard* No. 5 (this J., 1914, 497), and a rapidly acting yeast such as Yeast Boulard Nos. 21 to 30. A pure culture of the *Mucor* is first grown in a small cooked grain mash, about one-sixth as large as the main mash, in a closed vat, under conditions which exclude infection. When the mould has developed sufficiently this mash is added to the main mash in an open wooden or iron vat. The yeast is added a few hours later, and within 48 hours both saccharification and fermentation are complete. Foreign organisms which gain access to the vat are not able to develop to a serious extent within this period, the alcohol produced serving to hold them in check. It is stated that the process can be used in this country according to the present laws, whilst processes in which *Mucors* are employed in closed vats are not permitted.—J. H. L.

Beverage; Non-alcoholic —. A. L. Straus, Baltimore, Md. U.S. Pat. 1,265,274, May 7, 1918. Date of appl., Aug. 4, 1917.

A FERMENTED malt liquor is freed from alcohol and treated with some or all of the following:—water, salt, hops, gum arabic, sugar, quassia, a chill-proofing preparation, potassium metabisulphite, and carbon dioxide.—J. H. L.

Beverage; Non-alcoholic — and process of producing the same. A. L. Straus, Assignor to Baltimore Process Co., Baltimore, Md. U.S. Pat. 1,265,275, May 7, 1918. Date of appl., Oct. 15, 1917.

A FERMENTED liquor, prepared from glucose without malt, is freed from alcohol and treated with some or all of the following:—water, salt, sugar, quassia,

hops, a foam-producing material, a preserving material, e.g., potassium metabisulphite, a chill-proofing material, and carbon dioxide.—J. H. L.

Alcoholic liquids [whisky]; Process for ageing —. J. Von Glahn, Brooklyn, N.Y. U.S. Pat. 1,265,838, May 14, 1918. Date of appl., Oct. 9, 1914.

ALCOHOLIC liquids containing fusel oils, e.g., whisky, are matured by storage in contact with charcoal and with finely divided wood which has been previously impregnated with matured alcoholic liquid.

—J. H. L.

Alcoholic liquors and the like; Apparatus for distilling in multiple effect —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 107,600, June 30, 1917. (Appl. No. 9466 of 1917.) Under Int. Conv., Oct. 19, 1914. Addition to Eng. Pat. 107,599 (see Fr. Pat. 478,885; this J., 1916, 1172).

SEE Addition of Oct. 19, 1914, to Fr. Pat. 478,885 of 1914; this J., 1916, 1173.

Solid alcohol and process of producing same. U.S. Pat. 1,266,080. See IIa.

XIXA.—FOODS.

Bread; Use of lime water in the preparation of —. Balland. *Comptes rend.*, 1918, 167, 198—201.

THE quantity of lime water necessary to produce a distinct yellow tinge with the flour is very variable, but is not sufficient completely to neutralise the acidity of the flour, so that panary fermentation is not inhibited. With regard to the quality of the bread, it is often difficult to distinguish between bread made with and without the addition of lime-water. The colour and taste of bread from very brown flour are apparently slightly improved by the use of lime-water.—W. G.

Milk; Colorimetric determination of lactose in —. A. J. P. Pacini and D. W. Russell. *J. Biol. Chem.*, 1918, 34, 505—507.

ONE c.c. of human milk is diluted with water to 100 c.c. About 0.5 gm. of solid picric acid is dissolved in about 10 c.c. of the diluted milk by stirring, and after 5 minutes, the solution is centrifuged for 10 minutes. A portion of the upper liquid is filtered to remove the fat, and 1 c.c. of the filtrate transferred to a long test-tube and heated with 1 c.c. of saturated sodium carbonate solution in boiling water for 20 minutes. After cooling and diluting to 10 c.c., the colour is compared with that obtained by similarly treating 1 c.c. of a standard 0.1% solution of pure lactose in saturated picric acid solution. When cow's milk is being tested, a slightly weaker standard solution of lactose should be employed.—H. W. B.

Milk; Casein of human —. A. W. Bosworth and L. A. Giblin. *J. Biol. Chem.*, 1918, 35, 115—117.

THE casein of human milk has all the properties associated with the casein of cow's and goat's milk. —H. W. B.

Milk as a source of water-soluble vitamins. T. B. Osborne, L. B. Mendel, E. L. Ferry, and A. J. Wakeman. *J. Biol. Chem.*, 1918, 34, 537—551.

MILK contains only a relatively small proportion of water-soluble vitamins. (See also *J. Chem. Soc.*, Sept., 1918.)—H. W. B.

Sour milk; Free lactic acid in —. L. L. Van Slyke and J. C. Baker. *J. Biol. Chem.*, 1918, **35**, 147—178.

SOUR milk contains lactates and free lactic acid, part of which is adsorbed by the caseinogen or casein. The amount of free lactic acid in milk that has soured under ordinary conditions may vary from 13 to 35 c.c. of N/10-acid per 100 c.c. of milk. About 20% of the free lactic acid is adsorbed by the casein. Methods are described for estimating the adsorbed and total free lactic acid in sour milk. (See further, *J. Chem. Soc.*, Sept., 1918.)

—H. W. B.

Nitrogen in liquids poor in nitrogen [e.g., milk]; Micro-Dumas estimation of —. G. Kraemer. *J. prakt. Chem.*, 1918, **97**, 59—60.

THE usual micro-Kjeldahl method for estimating nitrogen in small quantities of a liquid such as milk can be replaced satisfactorily by a micro-Dumas process. A small copper boat of approximately 0.25 c.c. capacity enclosed in a small thin-walled glass dish covered with a glass plate is weighed to the fifth decimal place, first empty and then filled with the milk. The boat is placed in a small vacuum desiccator and kept at 30°—35° C. until the water has evaporated; the boat and its contents are then introduced into the combustion tube and covered with fine copper oxide, preparatory to the combustion. The weighing, drying, and combustion occupy an hour.—D. F. T.

Cream; Pasteurisation of —. C. Larsen, J. M. Fuller, V. R. Jones, H. Gregory, and M. Tolstrup. *South Dakota State Coll. Agric., Bull. No. 171*. Nov. 1916, 529—548. *Bull. Agric. Intell.*, 1918, **9**, 621—622.

IN some European countries the whole of the butter, and in the United States about two-thirds, is made from pasteurised cream. The effect of pasteurising cream at different temperatures was studied, using a coil vat of 150 galls. capacity, operated by a 20 HP return tubular boiler and a 15 HP engine to run the coil. The cream was heated for 25 mins. at 140° F. (60° C.), or for 10 mins. at 160° F. (71° C.), or momentarily to 180° F. (82° C.) followed by immediate cooling. The middle temperature (160° F.) effected the greatest reduction in the total number of organisms; 160° and 180° F. were more effective than 140° F. in killing moulds and non-acid forming organisms. The only appreciable effects of pasteurisation on the composition of the cream were a decrease in moisture-content and a slight decrease in acidity. Microscopical comparison of the cream before and after heating showed a tendency for the higher temperatures (160° and 180° F.) to cause the fat globules to coalesce. Pasteurisation had no important influence on the chemical composition of the butter produced, nor did the high temperatures unfavourably affect the "body" of the product. The butter made from cream pasteurised at 180° F. showed the best keeping qualities.—J. H. L.

Butter; Rancidity of —. E. S. Guthrie. *Dairy Sci., Baltimore*, 1917, **1**, 218—233. *Bull. Agric. Intell.*, 1918, **9**, 622—623.

APART from biological agencies (which were as far as possible excluded in the author's experiments) the purely chemical and enzymic transformations which occur in butter do not affect the iodine value considerably and do not cause rancidity; neither does exposure to high temperatures, light, and air. Truly rancid butter is rarely found, strong flavour

being often erroneously referred to as rancidity. The original paper contains a bibliography of the subject.—J. H. L.

Cascin; Preparation of pure —. L. L. Van Slyke and J. C. Baker. *J. Biol. Chem.*, 1918, **35**, 127—136.

CASEIN is precipitated in a pure form from undiluted milk by the addition of lactic or other acid, the milk being maintained in rapid motion by means of a rapidly revolving mechanical stirrer.—H. W. B.

Cascin; Action of pancreatic enzymes upon —. H. C. Sherman and D. E. Nenn. *J. Amer. Chem. Soc.*, 1918, **40**, 1138—1145.

A COMPARATIVE study of the hydrolysis of casein by various preparations derived from the pancreas. Extraction of high-grade commercial pancreatin with 50% alcohol leaves a residue having about the same proteolytic activity as the original pancreatin. The sac precipitate which settles out of the amylase solution during the dialysis in 50% alcohol, preceding the final precipitation of the amylase preparation (Sherman and Schlesinger, *J. Amer. Chem. Soc.*, 1912, **34**, 1110; 1915, **37**, 1306; this *J.*, 1915, 627), has 15 times the proteolytic activity of the original pancreatin and about 4 times that of the most active commercial trypsin. The final preparation of pancreatic amylase purified as described previously (*loc. cit.*) has proteolytic activity fully equal to that of high-grade trypsin. (See also *J. Chem. Soc.*, Sept., 1918.)—C. S.

Barley; Dietary qualities of —. H. Steenbock, H. E. Kent, and E. G. Gross. *J. Biol. Chem.*, 1918, **35**, 61—74.

BARLEY, when tested by feeding it to rats, was found to contain an abundance of water-soluble vitamins, but was deficient in salts, protein, and fat-soluble vitamins.—H. W. B.

Nutritive factors in plant tissues. I. The protein factor in the seeds of cereals. T. B. Osborne, L. B. Mendel, E. L. Ferry, and A. J. Wakeman. *J. Biol. Chem.*, 1918, **34**, 521—536.

PROTEIN concentrates were prepared from various cereals by treating them with diastase to remove the starch, and rats were fed on diets containing these various protein concentrates as sole sources of protein, with the exception of a small proportion of yeast added in each case to supply the necessary water-soluble vitamins. Normal growth was obtained with the concentrates from rice and barley, but not with those from maize or oats.—H. W. B.

Carbohydrates and fats; Comparative study of the influence of — on the nutritive power of alimentary proteins. F. Maignon. *Comptes rend.*, 1918, **167**, 172—175.

FEEDING experiments with rats, using diets of egg-albumin and fat, or egg-albumin and starch, or a mixture of the three, indicate that the albumin is better utilised with fat than with starch, the minimum of albumin necessary being much lower with the former than with the latter.—W. G.

Ovalbumin; Preparation of — and its refractive indices in solution. A. R. C. Haas. *J. Biol. Chem.*, 1918, **35**, 119—125.

THE crystallisation of ovalbumin from ammonium sulphate solutions only succeeds when the hydrogen ion concentration of the solution lies between 10^{-5}

and 10%. The refractive indices of ovalbumin in various solvents have been found to obey Robertson's law (J. Phys. Chem., 1909, 13, 472).—H. W. B.

Vegetable gums in food products; Detection of —. A. A. Cook and A. G. Woodman. J. Ind. Eng. Chem., 1918, 10, 530—533.

From 50 to 200 grms. of the sample is diluted with water, 5 c.c. of dilute acetic acid and 25 c.c. of 10% tannin solution are added, the mixture is heated for 30 mins., centrifuged, and filtered; the filtrate is again treated with tannin solution (40 to 50 c.c.), heated, centrifuged, and filtered. Casein, proteins, gelatin, fat, etc., are thus removed. The clear filtrate is then mixed with twice its volume of acetone, centrifuged, and the precipitate collected, washed twice with acetone, dissolved in 50 c.c. of warm water, acidified slightly with acetic acid, 10 c.c. of ammonia (sp. gr. 0.9) is added, the mixture centrifuged, and filtered; calcium phosphate from the milk solids (if present) is thus removed. The gums are then precipitated from the filtrate by acidifying the latter with acetic acid and adding alcohol, one volume at a time. If, after the addition of five vols. of alcohol, a precipitate is not obtained gums are absent. The quantity of alcohol required for the precipitation and the character of the precipitate give an indication of the kind of gum present. For example, one volume of agar solution requires 3 to 4 vols. of alcohol, the precipitate is finely-divided and, when air-dried, remains soft and non-coherent; gum arabic requires 2 vols. of alcohol, the precipitate is flocculent and dries to a powder; Indian gum requires 2 to 3 vols. of alcohol and gives a stringy precipitate which dries to a dark-coloured tough film; gum tragacanth gives jelly-like clots with 2 vols. of alcohol, the clots drying to a semi-transparent layer; dextrin requires 3 vols. of alcohol, giving a fine, white sticky precipitate which tends to become hard when dried and kept. Microscopic examination of the tannin precipitate may reveal the characteristic diatoms found in agar if this gum is present, whilst the volatile acidity of Indian gum is of value as a confirmatory test. When pectins are present they may be removed from the gums by treating the ammoniacal solution of the latter (see above) with a few drops of iron-tannin solution before the acetic acid is added. Dextrins are separated from the gums by heating 0.5 gm. of the dried gum for 5 mins. in a water-bath with 50 c.c. of water and 25 c.c. of hydrochloric acid (sp. gr. 1.2). The method described above will detect the presence of 0.1 gm. of gum in 100 grms. of complex food substance.—W. P. S.

Baking powder; Determination of carbon dioxide in —. H. Scheilbach and F. Bodinus. Z. Unters. Nahr. Genussm., 1918, 35, 236—240.

In the method described the carbon dioxide evolved from the baking powder is absorbed in 33% potassium hydroxide solution and the quantity of potassium carbonate formed is determined volumetrically; 5% phosphoric acid solution is used to decompose the carbonate in the baking powder.

J. Tillmans and O. Heublein (*ibid.*, 257—266) find that the above method is untrustworthy.—W. P. S.

Coffee substitutes; Microscopic examination of —. C. Griebel. Z. Unters. Nahr. Genussm., 1918, 35, 223—225, 272—277.

DIAGRAMS are given showing the characteristic features of the seeds of the common corn spurrey (*Spergula arvensis*, L.) and the so-called acacia (*Robinia pseudacacia*, L.), both of which are used

in Germany as coffee substitutes; the former seeds contain numerous conglomerations of starch cells, whilst the latter are free from starch but contain considerable quantities of fat and protefins. The microscopic appearance of the seeds of bird's foot (*Ornithopus sativus*, Brot.) is also described.

—W. P. S.

Coffee substitutes containing lupine seeds. H. Eckenroth. Z. Unters. Nahr. Genussm., 1918, 36, 240—242.

THE BITTER taste of lupine seeds is due to the presence of alkaloids, saponins, etc., and although processes have been suggested for the removal of these substances, they are unreliable. Moreover, roasting does not destroy the bitter substances, and the author is of opinion that lupine seeds should not be used as a coffee substitute. (Compare Gonnerman, this J., 1918, 483 A.)—W. P. S.

Cottonseed meal; Uniform nitrogen determination in —. J. S. McHargue. J. Ind. Eng. Chem., 1918, 10, 533—535.

THE FOLLOWING points should be observed in the determination of nitrogen in cottonseed meal. The sample should be ground finely (40-mesh sieve) in order to obtain a homogeneous mixture of hulls and meal. When mercury is used as catalyst, loss of nitrogen may occur if the boiling is prolonged for more than 2 hrs.; the digestion period, using copper sulphate as catalyst, depends on the amount of sodium sulphate added, 12 grms. being sufficient to complete the decomposition in 2 hrs. Sodium sulphate is as efficient as potassium sulphate in the digestion. Precipitation of the copper as cuprous chloride facilitates the boiling and shortens the time of distillation. Suitable quantities of materials and conditions for the determination are:—cottonseed meal, 0.7 gm.; crystallised copper sulphate, 0.5 gm.; anhydrous sodium sulphate, 12 grms.; sulphuric acid, 25 c.c.; time of digestion, 2 hrs.—W. P. S.

Alfalfa [lucerne] hay; Isolation and identification of stachydrine from —. H. Steenbock. J. Biol. Chem., 1918, 35, 1—13.

STACHYDRINE is present in small amount in the phosphotungstic acid fraction of the aqueous extract of lucerne hay. The presence of stachydrine may vitiate values for histidine and lysine obtained by the Van Slyke method and for lysine obtained by the Kossel method when these values are obtained directly on the feeding material itself.—H. W. B.

Leaf hay; Composition and feeding value of —. F. Honcamp and E. Blanck. Landw. Versuchs.-Stat., 1918, 91, 291—308.

DRIED leaves of the beech, maple, lime, birch, alder, chestnut, etc., form a valuable feeding stuff; they contain from 10 to 23% of protein, 2 to 10% of fat, and 17 to 22% of crude fibre.—W. P. S.

Heather and reindeer moss; Composition and di- F. Honcamp and E. Blanck. Landw. Versuchs.-Landw. Versuchs.-Stat., 1918, 91, 223—251.

HEATHER meal contains about 7% of proteins, 9% of fat, 8% of ash, and 12 to 21% of crude fibre; when prepared from the leaves and flowers only it has a food value approximating that of poor quality hay. Reindeer moss is of little value as a fodder; it contains about 2% of fat and 4% of proteins.

—W. P. S.

Pigweed, Amaranthus retroflexus L.; Proximate analysis of the seed of the common —. E. P. Harding and W. A. Egge. J. Ind. Eng. Chem., 1918, 10, 529—530.

PIGWEEED grows abundantly in the State of Minnesota; analysis of the seeds yielded the following results:—Moisture, 11.28; ash, 4.33; ether extract, 7.03; proteins, 18.57; starch (by diastase) 32.40, (by acid inversion) 39.77; reducing sugars, trace; other sugars, 2.08; crude fibre, 10.59; tannin and undetermined, 6.35%. The seeds might be used as a poultry food and the meal as a cattle food.—W. P. S.

Silver maple (Acer saccharinum); Analysis and composition of the seed of the —. R. J. Anderson. J. Biol. Chem., 1918, 34, 509—513.

THE seed of the silver maple has a high food value. It contains 42% starch, 27.5% protein, 16% sugar, and 5% of ash, consisting chiefly of potassium phosphate. The chief protein is a globulin. The phosphorus in the seed is present chiefly in organic combination.—H. W. B.

Determination of essential oils in non-alcoholic flavouring extracts. Boyles. See XX.

Abnormalities in the formol titration method. Jodidi. See XXIII.

Method for making electrometric titrations of solutions containing protein. Baker and Van Slyke. See XXIII.

PATENTS.

Grain; Method and apparatus for treating — [with ozonised air]. P. J. H. Moore, Chicago, U.S.A. Eng. Pat. 116,952, Apr. 12, 1917. (Appl. No. 10,126 of 1917.)

IN a process of treating unbroken grain, such as wheat, preparatory to storage, the grain is fed continuously into the top of a tall chamber and discharged from the bottom, at such a rate that the chamber remains full, whilst ozonised air contained in an adjoining chamber is injected into the grain chamber through openings at different heights in the common wall. Each opening is situated below an inverted V-shaped trough extending across the grain chamber, and the ozonised air issuing from below these troughs percolates upwards through the descending column of grain and escapes from the top of the chamber. The air is ozonised by silent electric discharge in apparatus comprising readily accessible I-shaped glass plates wound with coils and separated by other insulating glass plates. —J. H. L.

Wheat and other grains; Process of treating —. A. C. Von Hagen, Kansas City, Mo. U.S. Pat. 1,265,700, May 7, 1918. Date of appl., Sept. 1, 1916.

THE grain is treated superficially in presence of moisture insufficient to saturate it, with a substance capable of yielding a halogen in the free state, e.g., calcium hypochlorite, or simultaneously with an alkali, such as calcium hydroxide, to neutralise the free acidity of the grain, and a hypochlorite, to exert a germicidal action.—J. H. L.

Egg food preparations. M. Cutler, London, Eng. Pat. 117,022, Nov. 28, 1917. (Appl. No. 17,597 of 1917.)

WHOLE eggs or the yolks alone, in liquid or powdered form, are mixed with a liquid prepared by boiling

linseed with water; a preservative such as borax may be added.—J. H. L.

Baking powder. A. H. Peter, Assignor to Royal Baking Powder Co., New York. U.S. Pat. 1,265,369, May 7, 1918. Date of appl., Sept. 16, 1916.

CLAIM is made to baking powders containing lactide and acid lactates as acid constituents.—J. H. L.

Curing meats. G. F. Doran, Omaha, Nebr., U.S.A. Eng. Pat. 107,593, June 28, 1917. (Appl. No. 9298 of 1917.) Under Int. Conv., Apr. 29, 1916.

SEE U.S. Pat. 1,212,614 of 1917; this J., 1917, 401.

Preserving fruits and other organic substances; Method of —. H. C. M. Franks, Brooklyn, N.Y., Assignor to Franks & Co., Inc. Reissue 14,489, June 25, 1918, of U.S. Pat. 1,232,271, July 3, 1917. Date of appl., Mar. 18, 1918.

SEE this J., 1917, 938.

XIXB.—WATER PURIFICATION; SANITATION.

Lime-sulphur solutions; Composition of —. O. B. Winter. J. Ind. Eng. Chem., 1910, 10, 538—545.

THE presence of hydrogen sulphide, calcium hydrosulphide, calcium hydroxyhydrosulphide, and the corresponding salts of other metals may be detected by titrating an aliquot portion of the sample with iodine until the yellow colour has disappeared and then repeating the titration using sodium nitroprusside to determine the end-point; after the polysulphide has been decomposed the blue colour of the nitroprusside remains as long as any sulphide sulphur is present. Ordinary lime-sulphur, which has stood for several days, does not contain any of the above-mentioned compounds, and cannot contain free lime, since any of the latter which may be present when the preparation is made gradually disappears. In freshly prepared lime-sulphur solution, the difference between the titrations with hydrochloric acid and ammoniacal zinc chloride solution is a measure of the free lime. When magnesium sulphate is added to a lime-sulphur solution there is a slight decrease in the content of monosulphide and of sulphide sulphur, the thiosulphate sulphur remains practically the same, magnesium replaces a part of the calcium forming magnesium polysulphide and calcium sulphate may separate, and a compound containing the SH radical is formed. The magnesium sulphate method for determining free lime in lime-sulphur solution is inaccurate. The sulphur which separates from lime-sulphur solution on standing is derived from the polysulphide and is not due to the presence of free sulphur. Orange-red crystals which separated from a concentrated lime-sulphur solution prepared with an excess of lime appear to consist of an additive compound of calcium oxide with calcium polysulphide, $2\text{CaO} \cdot \text{CaS}_x \cdot 11\text{H}_2\text{O}$, but it is improbable that they exist in the solution form.—W. P. S.

Disinfection; Adsorptive — by metallic combination and disperse galvanic elements. H. Bechhold. Z. Elektrochem., 1918, 24, 147—150.

FINELY divided wood charcoal, fullers' earth, silicic acid, animal charcoal, iron oxide, alumina, calcium oxalate, and barium sulphate all act as disinfectants toward *Staphylococcus* due to their adsorptive properties. The bacteria are retained

living on the surface of the adsorption medium. The amount of adsorption varies from 99.97% with wood charcoal to 62.32% with alumina. The deposition of thin films of metals on the adsorption medium (gold, silver, copper, or mercury) has the effect of killing the adsorbed bacteria, the action of the metal being specific. A mixture of two metals is still more effective in certain cases. Thus in the case of typhus, mercury alone leaves 16,883 colonies, whereas mercury and copper together leave only one colony. Moreover, on injecting colloidal metals into mice, mixtures of metals were found to be more deadly than the single metals, thus: 4% silver killed in 4 days, 4% mercury had not killed in 11 days, but a mixture of 4% mercury and 4% silver killed in 6 hours.—J. F. S.

Analysis of air from a mine fire. Blakeley and Geist. See IIIA.

PATENTS.

Furnaces; Incinerating — J. W. Stokes, Dallas, Tex., U.S.A. Eng. Pat. 117,417, Feb. 26, 1918. (Appl. No. 3385 of 1918.)

An arched furnace chamber has a saucer-shaped floor and curved rear wall. The furnace has three grates: one on the side of the chamber furthest from the stack and separated from the main body of the chamber by a baffle-wall is used for burning fuel; one in the centre of the front wall for completing the combustion of the garbage or other material to be incinerated; and an auxiliary grate on the side nearest the stack. Garbage is fed through a charging door in the top of the furnace on to an elevated grate supported on arches and having a forward inclination. The combustion gases pass above and below this grate and partly incinerate the material, the combustion being completed on, and the cinders discharged from, the centre grate.—W. H. C.

Black rot and other fungoid and bacterial diseases in leaf-tobacco; Process for preventing the development of — W. W. Garner and E. G. Reinhardt, Washington, D.C. U.S. Pat. 1,268,070, May 28, 1918. Date of appl., Jan. 10, 1918. (Dedicated to the public.)

The process consists in controlling the moisture content of tobacco by subjecting the material to the action of heated air under varying conditions of temperature and humidity, these being alternated, thereby preventing the growth of fungoid and other diseases in leaf tobacco.—W. G.

Separation and settlement of solids and semi-solids from chemical and like manufacturing liquids. Eng. Pat. 117,472. See I.

Method of producing high-boiling phenols. Eng. Pat. 116,905. See III.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Cinchona alkaloids; Identification of the — by optical-crystallographic measurements. E. T. Wherry and E. Yanovsky. J. Amer. Chem. Soc., 1918, 40, 1063—1074.

PURIFIED samples of cinchonine, cinchonidine, quinine and quinidine were separately crystallised from alcohol and from benzene and the crystals examined under the microscope in ordinary light, parallel polarised light and convergent polarised

light; the refractive indices were determined by the immersion method in solutions of potassium mercuric iodide and glycerol of known indices. The results are given in tables which have been used successfully in the identification of the four alkaloids in the products obtained by fractional crystallisation of mixtures from alcohol or benzene. The general procedure in examining medicinal preparations for the presence of these alkaloids is illustrated in the case of a proprietary remedy presumably containing the alkaloids as sulphates. A few of the pills were ground with potassium carbonate, suspended in water, and shaken with chloroform. The gummy residue obtained from the chloroform extract after the evaporation of the solvent was shaken with dilute sulphuric acid, the filtered solution treated with dilute aqueous ammonia, and the resulting grey precipitate extracted with a few c.c. of benzene. The benzene layer was separated and allowed to evaporate. A drop of the concentrated solution was placed on a microscope slide and covered with a slip when evaporation was nearly complete. Crystals soon formed round the edge of the cover glass consisting of three distinct types, which were easily recognised as quinine, cinchonidine, and cinchonine respectively. The result was confirmed by immersing the crystals in liquids of known refractive indices. (See also J. Chem. Soc., Sept., 1918.)—C. S.

Alkaloid from the common broom; A new volatile — A. Valeur. Comptes rend., 1918, 167, 163—164.

In addition to the fixed alkaloid, sarothamnine, the author has isolated from the mother liquors in the manufacture of sparteine sulphate, a volatile alkaloid genisteine, $C_{11}H_{15}N_3$, m.pt., 60.5° C.; b.pt., 139.5°—140.5° C. at 5 mm. (corr.), 177°—178° C. at 22 mm. (corr.). It readily absorbs water vapour, forming a hydrate with 1 mol. H_2O ($[\alpha]_D = -52.3$ in 4% alcoholic solution). (See further J. Chem. Soc., Sept., 1918.)—W. G.

Coumarin; Detection and determination of — in *fascitious vanilla extracts.* H. J. Wichmann. J. Ind. Eng. Chem., 10, 535—537.

TEN c.c. of the extract is rendered alkaline with 10% sodium hydroxide solution, 15 c.c. of water is added, and the mixture is extracted with 20 c.c. of ether. The ethereal solution is shaken with a few c.c. of concentrated alcoholic potassium hydroxide solution, washed with 10 c.c. of water, mixed in a test-tube with 1 c.c. of 50% potassium hydroxide solution, the ether and water evaporated, and the residue of potassium hydroxide fused. If coumarin is present, a greenish coloration develops as the water evaporates. This colour disappears as the heating is continued, the coumarin being converted into salicylic acid. The mass is cooled, dissolved in water, the solution acidified with sulphuric acid, extracted with benzene, and the benzene solution tested for salicylic acid by the ferric chloride reaction. The quantity of coumarin present is determined by treating 50 c.c. of the alcoholic extract with lead acetate, diluting to 100 c.c., filtering, and removing the excess of lead by the addition of dry potassium oxalate. Fifty c.c. of the filtrate is then extracted with ether, the ethereal extract treated with an excess of alcoholic potassium hydroxide solution and a few drops of phenolphthalein, and the vanillin salt removed by washing with several portions of 10 c.c. of water. The disappearance of the red coloration indicates that the washing is sufficient. The ether is then evaporated, and the residue of coumarin dried and weighed. The amount of the residue varies from 98 to 102% of the quantity of coumarin present.—W. P. S.

Acetylaminophenyl salicylate. Preparation of salophen. R. Q. Brewster. J. Amer. Chem. Soc., 1918, 40, 1136—1138.

The investigation was undertaken in consequence of the difficulty of obtaining good yields of salophen. The reduction of crude *p*-nitrophenyl salicylate must be effected in a non-aqueous solvent in order to avoid hydrolysis of the ester and of its reduction product; with glacial acetic acid and zinc dust the yield of *p*-aminophenyl salicylate is 45% of the theoretical. Salophen was prepared without isolating the free base. Crude *p*-nitrophenyl salicylate (5 grms.) dissolved in 20 c.c. of glacial acetic acid (rendered anhydrous by adding sufficient acetic anhydride) was added slowly, with shaking, to 20 grms. of zinc dust and 15 c.c. of anhydrous acetic acid. After 20 minutes the liquid was decanted, the solid residue was washed with anhydrous acetic acid, and the combined liquors heated under a reflux condenser for 20 hours, cooled, and poured into 5 vols. of water. The crude salophen, m.p. 175°—180° C., was obtained in a yield of 55%, and a further 5% was obtained from the filtrate after evaporating the acid at 50° C. in a vacuum. After purification with charcoal and 50% alcohol the salophen had m.p. 187° C. *p*-Nitrophenyl salicylate crystallised once from alcohol and twice from petroleum spirit of high boiling point, has m.p. 145°—147° C. Using this material the yield of the free base is increased to 73%, and that of salophen to 80%, of the theoretical.—C. S.

Esters; Anodic formation of — simultaneously with nitrobenzene and o-nitrophenol from mono-nitrobenzoic acids. C. Schall. Z. Elektrochem., 1918, 24, 154—157.

MIXTURES of potassium *o*-nitrobenzoate and the free acid in acetic anhydride solution give on electrolysis as anode products, nitrobenzene, *o*-nitrophenol, and the *o*-nitrophenyl ester of *o*-nitrobenzoic acid. The yield varies very much with temperature. A concentrated aqueous solution of potassium acetate and *o*-nitrobenzoate on electrolysis yields nitrobenzene, *o*-nitrophenol, and methyl-*o*-nitrobenzoate. (See also J. Chem. Soc., 1918, i, 389.)—J. F. S.

Malonic acid; Detection and identification of —. Bougault. Ann. Chim. Analyt., 1918, 23, 154—155.

THE method depends on the condensation of malonic acid with cinnamic aldehyde to form cinnamylidenemalonic acid which is almost insoluble in water; it is a yellow substance, m.p. 298° C. A quantity of 0.1 gm. of malonic acid, sodium malonate, or calcium malonate, is mixed with 15 drops of cinnamic aldehyde and 1 c.c. of acetic acid and heated in a sealed tube for 10 hrs. at 100° C. The mixture is then saturated with sodium carbonate, filtered, the cinnamylidenemalonic acid precipitated by the addition of alcohol, collected, dried at 100° C., and weighed. The yield is 0.119 gm. for each 0.10 gm. of malonic acid present.—W. P. S.

Amyl acetate and similar solvents; Manufacture of — from petroleum pentane. B. T. Brooks, D. F. Smith, and H. Essex. J. Ind. Eng. Chem., 1918, 10, 511—515.

THE chlorination of the pentane fraction (b.p. 25° to 45° C.) is carried out by passing chlorine through a number of small orifices into a large quantity of cold pentane, the operation being stopped when the mixture contains about 20% of chlorine derivatives. The mixture should be kept at 10° C., or lower, during the operation, and the process is controlled by observing the sp. gr. of the mixture, a monochloride content of 20% being indicated by a sp. gr. of 0.820. Fractional distillation of the mono-

chlorides affords an opportunity of rejecting material of unsuitable b.p., and the monochloride product thus obtained (b.p. 95°—140° C.) will contain about 90% of actual monochloride. The chloropentane is converted into amyl acetate by heating under pressure with sodium acetate and acetic acid in the presence of a solvent (alcohol, acetone, or amyl acetate); heating for 5 to 9 hrs. at 195° to 200° C. under a pressure of 180 to 230 lb. gives a yield of amyl acetate varying from 55 to 63% of the theoretical quantity. This synthetic amyl acetate cannot be distinguished from ordinary amyl acetate as regards its solvent power for cellulose esters, etc. It is doubtful if the amylenes, obtained as a by-product in the acetylation of chloropentane, can be converted profitably into alcohols or acetates. The estimated costs of producing 600 gallons of synthetic amyl acetate daily are given as:

	Dollars
Gasoline, 990 galls. at 40 cents ...	396.0
Chlorine, 5200 lb. at 2.5 cents ...	130.0
Sodium acetate, 4880 lb. at 15 cents ...	732.0
Soda ash, 1450 lb. at 3 cents ...	43.5
Interest and depreciation ...	30.3
Labour ...	48.0
Fuel and power ...	40.0
Total ...	1,419.8

—W. P. S.

Acetone [in methyl alcohol]; Determination of —. A. J. Field. J. Ind. Eng. Chem., 1918, 10, 552.

KEELER'S modification of the Robineau and Rollin method (this J., 1897, 569) was found to yield the most accurate results; the presence of alcohol and the time of shaking did not influence the percentage of acetone. Messinger's method (this J., 1889, 138) yielded erratic results even when arsenious acid was used in place of thiosulphate for titrating the unused iodine (see Vaubel and Scheuer, this J., 1905, 252).—W. P. S.

Essential oils; Determination of — in non-alcoholic flavouring extracts. F. M. Boyles. J. Ind. Eng. Chem., 1918, 10, 537—539.

THE so-called non-alcoholic flavouring extracts consist of an emulsion of the respective essential oils in mucilage of acacia, tragacanth, or other gums; glycerol is often present. To determine the essential oil in lemon, orange, almond, anise, and nutmeg extracts, 10 c.c. of the emulsion is measured in a graduated cylinder, transferred as completely as possible to a 50 c.c. flask, the cylinder is rinsed with 95% alcohol and, by the aid of a glass rod, all the precipitated gum, etc., is brought into the flask; the contents of the latter are then diluted with alcohol to 50 c.c., mixed, filtered after 30 mins., and the essential oil determined by the American official method in an aliquot portion of the filtrate. Direct steam distillation of the extract gives satisfactory results in the case of lemon, orange, and peppermint extracts provided that control distillations are made using extracts of known essential oil content to ascertain the quantity of essential oil recovered; this usually amounts to 90—95% of the amount present. In the case of cassia, cinnamon, and clove extracts the following method may be used:—10 c.c. of the extract is diluted to 50 c.c. with 95% alcohol, filtered, and 10 c.c. of the filtrate mixed with 50 c.c. of water and 1 c.c. of hydrochloric acid (1:1) and then extracted several times with ether. The ethereal solution is filtered through cotton wool, evaporated on a water-bath, the residue dried in a desiccator for 3 mins., and weighed.—W. P. S.

Constitution of dieyanodiamide. Hale and Vibrans.
See XVI.

PATENTS.

Para-aminophenol; Manufacture of derivatives of —. O. Imray, London. From Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 116,920, June 25, 1917. (Appl. No. 9101 of 1917.)

SEE U.S. Pat. 1,263,238 of 1918; this J., 1918, 349 A. *p*-Lactylaminophenol allyl ether and α -bromoisovaleryl-*p*-aminophenol allyl ether form lustrous leaflets melting at 87° C. and 131° C. respectively. Isovaleryl-*p*-aminophenol allyl ether forms small lustrous needles, m.pt. 95° C.

Local anæsthetics; Preparation of substances for use as —. H. Sefton-Jones, London. From N. Nagai, Tokyo-fu, Japan. Eng. Pat. 117,486, July 14, 1917. (Appl. No. 10,237 of 1917.)

THE preparation of two new alkaloids, "allocain S" (O-benzoyldiethylmydriatin) and "allocain A" (O-benzoyl-ethylmydriatin), both possessing local anæsthetic properties, is claimed. Mydriatin (α -phenyl- β -aminopropanol) in the form of its sulphate or hydrochloride is warmed with an ethyl halide in aqueous solution in the presence of sodium carbonate under a reflux condenser at 30°–40° C. for several hours. Sufficient ether is then added, after cooling, to dissolve the ethyl- and diethylmydriatin, and to the mixture a benzoyl halide or benzole anhydride is added and the mixture is vigorously shaken. The ethereal layer is separated and to it dilute hydrochloric acid is gradually added and the mixture shaken until the aqueous layer is acid. The ethereal and dilute acid solutions are separated and on evaporating the latter under reduced pressure "allocain S" crystallises out in the form of its hydrochloride. The ethereal solution, which contains N-benzoyl-ethylmydriatin, is evaporated to remove the ether and the residue is heated in a water bath with 30% hydrochloric acid, and finally diluted with water until no further turbidity occurs. The turbid solution is filtered and the filtrate shaken with ether. The acid solution is separated from the ether, filtered if necessary, and evaporated on a water bath, during which process the N-benzoyl derivative is converted into an O-benzoyl derivative, and "allocain A" crystallises out as its hydrochloride, and may be purified by recrystallisation from water.—W. G.

1,2,4-Methylhydroxyisopropylbenzene [carvacrol]; Process of producing —. R. H. McKee, Ridgefield Park, N.J. U.S. Pat. 1,265,800, May 14, 1918. Date of appl., Apr. 7, 1917.

"SPRUCE turpentine" (a by-product from the manufacture of wood pulp; this J., 1918, 296 A, 364 A) is sulphonated, and an alkali salt of the sulphonic acid formed is fused with caustic alkali, and the dissolved melt treated with acid.—J. H. L.

Dimethylaminotetraaminoarsenobenzene; Process of preparing stable solutions of —. L. Aeh, Mannheim, A. Rothmann, Heidelberg, and G. Giemsa, Hamburg. Assignors to Farb. vorm. Meister, Lucius, und Brünning, Höchst, Germany. U.S. Pat. 1,265,864, May 14, 1918. Date of appl., Jan. 10, 1914.

A SALT of dimethylaminotetra-aminoarsenobenzene is treated with a soluble bicarbonate in presence of water. The solution formed, which probably contains the substance in the form of carbamate, has a yellowish colour which darkens on exposure to air, and yields dimethylaminotetra-aminoarsenobenzene on treatment with hydrochloric acid. (Cp. Ger. Pat. 269,660; this J., 1914, 374.)—J. H. L.

Bismethylaminotetraaminoarsenobenzene; Process of preparing derivatives of — which are soluble in water. L. Aeh and H. Dieterich, Mannheim. Assignors to Farb. vorm. Meister, Lucius, und Brünning, Höchst, Germany. U.S. Pat. 1,265,865, May 14, 1918. Date of appl., June 15, 1915.

DERIVATIVES of 4,4'-bismethylamino-3,5,3',5'-tetra-aminoarsenobenzene substituted in the benzene nucleus, e.g., the 2,2'-dichloro-derivative, are dissolved in water by means of an alkali bicarbonate or by successive treatment with an alkali and carbon dioxide. (Cp. Eng. Pat. 8759 of 1915; this J., 1915, 1072.)—J. H. L.

Surgical dressings; Process for manufacturing —. K. J. Holliday, Glen Osborne Borough, Pa., Assignor to Holliday Chemical Co., Neville Island, Pa. U.S. Pat. 1,268,076, May 28, 1918. Date of appl., Mar. 29, 1918.

PARAFFIN wax and beeswax are mixed in the proportion of 95 to 65% of the former and 5 to 35% of the latter, and the mixture, with or without the addition of 0.1–5% of a gum of the elemi group, is emulsified with a base. The waxes and soaps of the emulsion are separated and then the soaps eliminated. A composition of paraffin and the esters and hydrocarbons of beeswax, having a m.pt. of 120°–140° F. (49°–60° C.), is thus obtained, which contains practically no free acids and is capable, when melted and applied to the flesh, of forming an elastic, non-cracking, and non-irritating covering.—W. G.

Defibrinated-blood antitoxin; Process for refining —. M. Dorset, Washington, D.C., and R. R. Henley, Tukoma Park, Md. U.S. Pat. 1,270,270, June 25, 1918. Date of appl., Feb. 27, 1918. (Dedicated to the public.)

DEFIBRINATED blood antitoxin is subjected to heat, and the coagulated hemoglobin, cell residues, and bacteria are removed by filtration without injury to the serum albumins, serum globulins, and antibodies. These three latter are then precipitated by acids, removed by filtration, redissolved, and reprecipitated, a refined, concentrated, and sterile antitoxin being thereby obtained. The process may be applied to phenolised hog cholera defibrinated blood antitoxin.—W. G.

Blood-serum; Process for the separation of —. M. Dorset, Washington, D.C., and R. R. Henley, Tukoma Park, Md. U.S. Pat. 1,270,271, June 25, 1918. Date of appl., Mar. 25, 1918. (Dedicated to the public.)

A NEUTRAL chemical salt is added to defibrinated blood, thereby causing a contraction of the cells and thus diminishing their volume and increasing the volume of the clear fluid without precipitation of the fibrinogen, serum globulins, or other soluble constituents.—W. G.

Glycols; Manufacture of — [from oil-gas]. H. Hibbert, Pittsburgh, Pa. U.S. Pat. 1,270,759, June 25, 1918. Date of appl., Oct. 15, 1915.

OIL-GAS is cracked by subjecting it to a temperature of 600°–900° C., and the resulting gaseous mixture is chlorinated. The chlorine compounds are saponified by heating the mixture under pressure with aqueous alkali carbonate, the product being a mixture consisting essentially of ethylene-, propylene-, and butylene-glycols.—W. G.

Process of hydrogenation. U.S. Pat. 1,266,782. See XII.

XXIII.—ANALYSIS.

Phosphoric acid; Estimation of — as ammonium phosphomolybdate. A. Villiers. *Bull. Soc. Chim.*, 1918, 23, 305—306.

THE author prefers his method (this J., 1893, 787) in which the phosphoric acid is precipitated and weighed as ammonium phosphomolybdate under definite conditions as more accurate than that of Clarens (this J., 1918, 352 A) in which the nitrogen in the ammonium phosphomolybdate precipitate is estimated and from that result the percentage of phosphoric acid calculated.—W. G.

Radium; The bisulphate method of determining —. H. H. Barker. *J. Ind. Eng. Chem.*, 1918, 10, 525—527.

THE mineral containing radium is mixed with sodium or potassium bisulphate and fused in a hard glass tube, the heating being continued long enough to expel all traces of radium emanation; the sides of the tube are washed down by introducing a small quantity of bisulphate and allowing it to fuse and run down the sides of the tube. The latter is closed with a stopper carrying two tubes, one extending to within an inch of the melt and the other just through the stopper. After the emanation has been allowed to accumulate for a given definite period, the tube is connected with the evacuated ionisation chamber of an electro-scope, bulbs containing sulphuric acid and concentrated sodium hydroxide solution, respectively, being inserted between the tube and the chamber; the air admitted to the tube passes through a sulphuric acid bulb. The tips of the tubes in the stopper are not broken until all the connections have been made. If the material under examination contains thorium, the gas must not be transferred directly to the electro-scope during fusion, but must be collected in a gas-burette to allow the decay of the thorium emanation.—W. P. S.

Osmium; A new reaction of —. L. Tschugaeff. *Comptes rend.*, 1918, 167, 235.

WHEN a solution containing osmium in the form of its tetroxide or as an osmium chloride is warmed for a few minutes with an excess of thiourea and a few drops of hydrochloric acid, the liquid acquires a deep red or a rose colour according to the concentration of the osmium. By this means the metal may be detected at a dilution of 1 in 100,000.—W. G.

Organic matter; New method of rapid destruction of —. P. Duret. *Comptes rend.*, 1918, 167, 129—130.

THE material is immersed in 10% sulphuric acid in a large flask, treated with 10—20 grms. of ammonium persulphate, and the mixture heated to boiling. When effervescence ceases a further 10—20 grms. of ammonium persulphate is added and the heating continued, this being repeated until all brown colour has disappeared and white fumes appear. After cooling, the mass is treated with water. The solution can be used for the detection of metals or metalloids. The method is simple and rapid and is applicable to urines, hairs, and wool, and to such substances as sugars, fats, glycerol, and cacodyl compounds.—W. G.

Formol titration method; Abnormalities in the —. S. L. Jodidi. *J. Amer. Chem. Soc.*, 1918, 40, 1031—1035.

AN explanation is given of the abnormalities which sometimes render untrustworthy Sørensen's formol titration method of estimating amino-acids, poly-

peptides, etc. The function of the formaldehyde is to convert the basic nitrogen in the molecule into a neutral group so that the carboxyl group can be accurately titrated. Irregularities occur when this function is incompletely performed or when the molecule contains other groups such as the phenol or guanidine group. (See also *J. Chem. Soc.*, Sept., 1918.)—C. S.

Electrometric titrations of solutions containing protein; Method for making —. J. C. Baker and L. L. Van Slyke. *J. Biol. Chem.*, 1918, 35, 137—145.

APPARATUS is described which permits of the electrometric titration of solutions containing protein by a reagent, the local chemical action of which is prevented by means of a rapidly-revolving mechanical stirrer. (See further, *J. Chem. Soc.*, Sept., 1918.)—H. W. B.

Ammonia; Determination of — in urine, serum, etc. H. Wiessmann. *Landw. Versuchs.-Stat.*, 1918, 91, 347—352.

TEN c.c. of the sample is mixed with 40 c.c. of water and distilled at 50°C. under 5—10 mm. pressure with the addition of 10 c.c. of 10% sodium carbonate solution; the distillate is collected in a definite quantity of standardised sulphuric acid. The distillation of the ammonia is complete in about 45 mins. Urea does not yield any ammonia under these conditions. (See also *J. Chem. Soc.*, Sept., 1918.)—W. P. S.

Determination of essential oils in non-alcoholic flavouring extracts. Boyles. See XX.

PATENTS.

Viscosity of fluids; Method of determining the — and means for use in connection with the same. A. G. M. Michell, Melbourne. Eng. Pat. 117,224, Feb. 21, 1918. (Appl. No. 3124 of 1918.) Under Int. Conv., July 12, 1917.

The viscosity of a fluid, e.g., oil, is measured by the time taken to detach, by a definite force, two

contiguous surfaces separated by a film of fluid.

A hollow stem, 4, is provided with a shallow cup, 2, at one end, the spherical surface of the cup having three slight projections, 3, symmetrically placed and about 1—2 mm. diameter and 0.01 mm. in height. The rim of the cup is recessed with a groove, 9, of slightly larger diameter. The cup is placed over a corresponding steel ball, 8, with a film of oil to be tested between them, and a thermometer may be placed in the hollow stem. The cup is lifted and the time taken for the ball to become detached is observed. The recessed groove being filled with oil, maintains the film between the surfaces during their separation. In a modification, the cup is inverted and the ball attached to one arm of a balance and counter-weighted. A definite lifting force is then applied by adding a known weight to the other arm of the balance, and the time determined as before. The viscosity is directly proportional to the time. The viscosity of a gas may be determined by supplying it to the capillary space between the ball and the cup through a passage in the base of the cup.

—W. F. F.

Hardness testing machines. W. and T. Avery, Ltd., and J. Dobson, Birmingham. Eng. Pat. 117,525, Aug. 30, 1917. (Appl. No. 12,453 of 1917.)

The specimen to be tested is mounted on a plate supported by the short arm of a lever, the long arm of which is connected through a system of levers to the short arm of a steelyard. The movement of the steelyard is limited by stops. The short arm is also connected through levers to an indicating mechanism, e.g., a pendulum or spring balance. The application of the test weight on the long arm of the steelyard presses a steel ball between the specimen below and a plate carried by a vertical screw above. The indicating pointer is deflected by the indentation of the specimen and is brought back to zero by screwing down the upper plate, the load on the steel ball due to the test weight being then a maximum.—W. F. F.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Baines. Composition for insulation of steam and hot-water pipes. 13,546. Aug. 21.

Becker and Olson. Composition of matter. 14,120. Aug. 30.

British Westinghouse Electric and Manufacturing Co. Condensers of the jet type. 13,990. Aug. 28. (U.S., Sep. 29, 1917.)

British Westinghouse Electric and Manufacturing Co. Steam-actuated ejectors. 13,991. Aug. 28. (U.S., Sep. 21, 1917.)

British Westinghouse Electric and Manufacturing Co. Condensers for steam, etc. 13,992. Aug. 28. (U.S., Oct. 1, 1917.)

Brown (Bangkok Dock Co.). Devices for removal of ash, dust, etc., from gases, etc. 13,741. Aug. 23.
Cowburn, and Cowburn and Cowpar. Carboy hampers or crates. 13,890. Aug. 27.

Crossfield and Sons, and Hilditch. Manufacture of catalysts. 14,096. Aug. 14.

Cruyt, and Heenan and Froude. Apparatus for treating and cooling air or gas. 13,905. Aug. 27.

Davis. Pulverisers. 13,964. Aug. 28.

Erith, and Erith's Engineering Co. 14,057. *See* II.

Fawcett, Preston, & Co., and Harris. Apparatus for separation of vapours or gaseous fluids from liquids. 13,962. Aug. 28.

Goldreich. Ovens. 13,771. Aug. 23.

Graemiger. Device for measuring or controlling velocity of flowing fluid. 13,609. Aug. 21. (Switz., Aug. 31, 1917.)

Hind. Mixing and kneading appliances. 13,494. Aug. 20.

Hoofnagle. 13,607. *See* XI.

Kent and Mulliner. 13,678. *See* II.

Kent-Johnston. Apparatus for drying vegetable, animal, or mineral substances. 13,955. Aug. 28.

Mason. Filter-presses. 13,557. Aug. 21.

Pradairol. Apparatus for purifying and drying steam. 14,098. Aug. 30. (Fr., July 7, 1917.)

Robertson. Compressed-air liquid-spraying machine. 13,857. Aug. 26.

Stein et Cie. Regenerative furnaces. 14,177. Aug. 31. (Fr., Sep. 8, 1917.)

Thunholm. Evaporating-apparatus. 13,760. Aug. 23. (Sweden, Aug. 23, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

12,258 (1917). Lea. Registering-apparatus chiefly for use in registering the amount of feed of granular and like substances. (118,333.) Sep. 4.

12,281 (1917). Burns. Process and apparatus for separation of suspended particles from gases. (118,334.) Sep. 4.

15,525 (1917). Barbet et Fils et Cie. Cooling-plates for continuous rectification apparatus. (110,910.) Aug. 28.

17,609 (1917). Bruce and Baynes. Apparatus for the transmission or exchange of heat. (118,375.) Sep. 4.

9444 (1918). Matousek. Centrifugal separators. (118,262.) Aug. 28.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING

APPLICATIONS.

Bates. Gas-producers. 13,673, 13,674. Aug. 22.

Bowler and others. 13,941. *See* XII.

Brown (Bangkok Dock Co.). 13,741. *See* I.

Brown and Galloway. Fuel briquettes, etc. 13,899. Aug. 27.

Burney. Apparatus for distillation of solid carbonaceous material. 14,176. Aug. 31.

Cruyt, and Heenan and Froude. 13,905. *See* I.

Curbishley. 14,022. *See* XIII.

Davidson and Liversedge. Gas-cleaning apparatus. 13,938. Aug. 27.

Docking, and Sharp and Preston. 13,715. *See* XVIII.

Docking, and Sharp and Preston. Gas and air mixing apparatus for producer or suction gas generators, etc. 13,777. Aug. 24.

Edwards. 13,531. *See* V.

Erith, and Erith's Engineering Co. Apparatus for drying and carbonising materials. 14,057. Aug. 29

Evans. Gas producers, etc. 13,957. Aug. 28.

Greensill. Oil fuel. 13,631. Aug. 22.

Hamon. Fuel. 13,533. Aug. 20.

Kent and Mulliner. Settings for retorts. 13,678. Aug. 22.

Levi. Refractory blocks, fuels, radiators, etc. 13,710. Aug. 23.

MacLaurin. Manufacture of lubricating greases. 13,831. Aug. 24.

McLeod. Apparatus for extracting products from peat, carbonaceous substances, etc. 13,638. Aug. 22.

Maxfield. Incandescent gas lighting. 13,684. Aug. 22.

Morris. 13,859. *See* III.

Oakbank Oil Co., and Wishart. 13,842. *See* VII.

Parkes and Pearson. Manufacture of mixtures of mineral oils and coal tar. 13,610. Aug. 21.

Piette, and Soc. Franco-Belge de Fouris à Coke. Coking-ovens. 13,670. Aug. 22.

Pryce-Jones. Manufacture of briquettes. 13,782. Aug. 24.

Silberrad. 13,699. *See* XX.

Stein et Cie. 14,177. *See* I.

Swinburne. 13,951. *See* XII.

Ten Bosch. Removing water from peat, etc. 13,463. Aug. 19. (Holland, July 3.)

Wellington. Apparatus for quenching coke. 13,452. Aug. 19.

Wellington. Apparatus for mixing gaseous fuels. 13,737. Aug. 23.

COMPLETE SPECIFICATIONS ACCEPTED.

11,764 (1916). Maxim. Conversion of heavy hydrocarbons into lighter hydrocarbons. (118,122.) Aug. 28.

11,891 and 16,806 (1917). Ionides. Gaseous combustion. (118,313.) Sep. 4.

12,151 and 12,722 (1917). Ottini. Apparatus for storing coal gas and the like for use in motor vehicles. (118,327.) Sep. 4.

13,784 (1917). Marks (Swan Process Oil Co.). *See* XII.

4812 (1918). Yates, Brayshaw, and Brayshaw. Burner for gas-fired furnaces. (118,239.) Aug. 28.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Morris. Process by which coal tar and/or dehydrated coal tar may be utilised in conjunction with mineral and/or shale oils. 13,859. Aug. 26.

Parkes and Pearson. 13,610. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Higgins. Solid and soluble dyes. 14,009. Aug. 29.

Soc. Chimique des Usines du Rhône, anc.

Gilliard, P. Monnet, et Cartier. Process for obtaining halogen derivatives of indigo and of its homologues. 13,618. Aug. 21. (Fr., Oct. 10, 1917.)

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Brunner. Manufacture of spinning and weaving material. 13,612. Aug. 21. (Holland, Oct. 20, 1917.)

Cater. Process of water-proofing and/or air-proofing, and material therefor. 13,719. Aug. 23.

Clark (Jespersen Paper Co.). Method of removing printers' ink from paper stock. 14,170. Aug. 31.

Edwards. Manufacture of an insulating material and a fuel from paper, etc. 13,531. Aug. 20.

Finch and Whiteside. Absorbent writing-paper. 13,901. Aug. 27.

Macdonald. Manufacture of vulcanised fibre. 14,125. Aug. 30.

Reid. Coating or impregnating thread, yarn, ropes, fabrics, etc. 14,192. Aug. 31.

Rinnman. Process of retting fibrous substances. 14,104. Aug. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

3651 (1917). Moore. Manufacture of pulp for making paper, paper boards, and the like. (118,291.) Sep. 4.

12,229 (1917). Jarmaln. Process for the separation of grease from wool-scouring or like effluents or liquors. (118,332.) Sep. 4.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Calico Printers' Association, and Roberts. Bleaching, dyeing, etc., fabrics. 14,147. Aug. 31.
Poulson. Sizing textile fabrics, etc. 13,785. Aug. 24.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Bergman and Larson. Manufacture of pure aluminium hydroxide and ammonium sulphate. 13,873. Aug. 26. (Sweden, Oct. 9, 1917.)

Bloch and Dreyfus. Process of manufacturing alkaline manganates. 13,792. Aug. 21.

Bloch and Dreyfus. Process of manufacturing potassium permanganate. 13,793. Aug. 21.

Carborundum Co. (Tone). Purified crystalline alumina, and method of making same. 13,998. Aug. 28.

Clarke, and Rare Metals, Ltd. Process for production of ammonia, ammonium hydrate, and ammonium salts. 13,471. Aug. 19.

Clarke, and Rare Metals, Ltd. Process for production of nitric and nitrous acids and manufacture of nitrates. 13,751. Aug. 23.

Cowper-Coles. Method of extraction of nitrogen from the air, etc. 13,886. Aug. 27.

Curphery. Production of chemical compounds. 13,596. Aug. 21.

Dunningham and Hargreaves. Manufacture of chlorides of sulphur. 13,812. Aug. 24.

Fellowes and Hyatt. Process for obtaining products from seaweed. 13,524. Aug. 20.

Ingham. 13,837. *See* XVII.

Lytle. Manufacture of lead compounds. 13,436. Aug. 19.

Oakbank Oil Co., and Wishart. Manufacture of sulphate of ammonia. 13,842. Aug. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

11,887 (1917). Dutt and Dutt. Process for the manufacture and production of potassium aluminate, alumina, and potassium carbonate. (118,155.) Aug. 28.

11,888 (1917). Dutt and Dutt. Process for the manufacture and production of sodium aluminate, alumina, and sodium carbonate. (118,156.) Aug. 28.

13,884 (1917). Statham. *See* XI.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Carborundum Co. (Tone). 13,998. *See* VII.

Darrah. Glazed bricks. 13,838. Aug. 26.

Ferneyhough. Utilisation of heat from potters' ovens, kilns, etc. 13,883. Aug. 27.

Levi. 13,710. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

12,117 (1917). Kiefer. *See* IX.

6398 and 6399 (1918). Haddan (Corning Glass Works). Manufacture of glass for absorbing ultra-violet radiations. (118,397 and 118,398.) Sep. 4.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Darrah. 13,838. *See* VIII.

Hines and Scott-Moncrieff. Cement. 13,567. Aug. 21.

COMPLETE SPECIFICATION ACCEPTED.

12,117 (1917). Kiefer. Bricks or building blocks. (114,137.) Sep. 4.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Alexander, Imbery, and Vint. Electrical device for automatically indicating correct temperature of electrically-heated steel before quenching to obtain correct hardening thereof. 13,698. Aug. 22.

Bailey and Hall. Furnaces for melting steel, etc. 14,139. Aug. 31.

Bodman. Metallic alloy. 14,149. Aug. 31.

Cowper-Coles. Process for Sherardising. 13,885. Aug. 27.

Henderson. Process for removing coatings from metals. 13,932. Aug. 27.

Jascowitz and Rosenbaum. Cleaning metals by electrolysis. 13,642. Aug. 22.

Levin. Means for recovery of solder from tin cans, etc. 14,000. Aug. 28.

Lord. Furnaces for heat treatment of metals. 14,113. Aug. 30.

Marino. Process for removing paint, varnish, and grease from iron, steel, and copper, rust from iron or steel, and oxide or sulphide from copper. 13,665. Aug. 22.

Morley. Preservative preparations for protection of metal surfaces. 13,663. Aug. 22.

Whibley. Welding metals. 14,131. Aug. 30.

Williams. Manufacture of armour plating. 13,629. Aug. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

6846 (1917). Cooper Co. Alloys. (113,259.) Aug. 28.

7329 (1917). Pescatore. *See* XI.

Jungner. Primary galvanic batteries with unalterable electrolyte. 14,105. Aug. 30. (Sweden, Sep. 4, 1917.)

Keene. Electric furnaces. 14,079. Aug. 30. (U.S., Sep. 5, 1917.)

Ridoni, and Soc. Talco e Grafiti Val Chisone. Manufacture of natural graphite electrodes. 13,984. Aug. 28. (Italy, Mar. 6.)

COMPLETE SPECIFICATIONS ACCEPTED.

7329 (1917). Pescatore. Electrodes for arc soldering. (118,296.) Sep. 4.

11,511 (1917). Cary. *See* X.

13,884 (1917). Statham. Electrolytic cells, adapted for the manufacture of caustic alkali from sodium chloride. (118,355.) Sep. 4.

13,956 (1917). Wade (Booth-Hall Co.). Electric furnaces. (118,357.) Sep. 4.
 17,942 (1917). Whitney. Electric secondary or storage batteries. (118,208.) Aug. 28.
 1907 (1918). Johnson (Commercial Truck Co.). Secondary or storage cells or batteries. (118,227.) Aug. 28.

3460 (1918). Travis, and Watson and Co. Supply of electrical energy to furnaces or other appliances. (118,233.) Aug. 28.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Bowler, Paterson, and Paterson's Productions, Ltd. Treatment of oils, vegetable fermented liquors, etc. 13,941. Aug. 27.

Dicker (Devik and Lebbe). Process of recovering fat or oil from fatty substances. 14,001. Aug. 28.
 Maclaurin. 13,831. *See* II.
 Swinburne. Treatment of oils. 13,951. Aug. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

12,032 (1917). Kimura. Preparing catalytic agents for hydrogenating oils. (118,323.) Sep. 4.

12,220 (1917). Jarmain. *See* V.

13,784 (1917). Marks (Swan Process Oil Co.). Process and apparatus for purifying oils. (118,353.) Sep. 4.

18,546 (1917). Talbot. *See* XIX.

2057 (1918). Barry, Ostlere, and Shepherd, and Barry. Treatment of linseed-oil fatty acids. (118,228.) Aug. 28.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Curbishley. Manufacture of carbon black. 14,022. Aug. 29.

Denniss. Colours for artists. 13,821. Aug. 24.

Henderson. 13,932. *See* X.

Marino. 13,665. *See* X.

Morley. 13,663. *See* X.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATIONS ACCEPTED.

11,473 (1917). Mellersh-Jackson (Morgan and Wright). Treatment of india-rubber and the like. (118,305.) Sep. 4.

4801 (1918). Moore. Device or apparatus for the drying or heat treatment of rubber or other material or articles. (118,394.) Sep. 4.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Ingham. Manufacture of algin. 13,837. Aug. 26.
 Jacobson and Wrathall. Washing and purifying sugar. 13,778. Aug. 24.

Pictet. Manufacture of levoglucosan. 13,530. Aug. 20. (Switz., Dec. 27, 1917.)

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Bayer and Orla-Jensen. Process for production of alcohol and yeast from seaweed. 14,946. Aug. 29. (Denmark, Aug. 16, 1917.)

Bowler and others. 13,941. *See* XII.

Docking, and Sharp and Preston. Gas-heated

cylinders for drying or roasting malt, etc. 13,715. Aug. 23.

COMPLETE SPECIFICATION ACCEPTED.

15,525 (1917). Barbet et Fils et Cie. *See* I.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Buckley. Preserving meat, etc. 13,427. Aug. 19.
 Hegney and Hegney. Sterilising milk. 13,656. Aug. 22.

Kent-Johnston. 13,955. *See* I.

Marshall. Process for sterilising and drying animal and vegetable matter. 13,774. Aug. 23.

West. Method of treating grain for preservation thereof. 13,811. Aug. 24.

COMPLETE SPECIFICATION ACCEPTED.

18,546 (1917). Talbot. Butter substitutes and the like, and the preparation of same. (118,215.) Aug. 28.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Confectionery Ingredients, Ltd., Kane, King, and Matthews. Manufacture of vanillin. 13,504. Aug. 20.

Confectionery Ingredients, Ltd., Kane, King, and Matthews. Manufacture of protocatechuic aldehyde. 13,505. Aug. 20.

Ingham. 13,837. *See* XVII.

Silberrad. Manufacture of ethylene. 13,699. Aug. 22.

Stevenson. Manufacture of acetic anhydride. 13,640. Aug. 22.

COMPLETE SPECIFICATION ACCEPTED.

10,183 (1917). Marks (Nagai). Manufacture of synthetic drugs. (118,298.) Sep. 4.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Barron and Barron. Method of coating photographic sensitised glass plates. 13,488. Aug. 20.

Barron and Barron. Method of stripping films off old negatives. 13,489. Aug. 20.

Camiller and Lyell. Multi-colour screens for natural-colour cinematography, and manufacture thereof. 13,461. Aug. 19.

Camiller and Lyell. Multi-colour screens for natural-colour photography, and manufacture thereof. 13,462. Aug. 19.

Stevenson. Manufacture of non-inflammable films or filaments for cinematography, etc. 13,569. Aug. 21.

XXII.—EXPLOSIVES; MATCHES.

COMPLETE SPECIFICATION ACCEPTED.

12,009 (1917). Aktiebolaget Carlit. Ammonium perchlorate explosives. (112,417.) Sep. 4.

XXIII.—ANALYSIS.

COMPLETE SPECIFICATION ACCEPTED.

13,635 (1917). Avery, Ltd., and Allcut. Impact-testing machines. (118,175.) Aug. 28.

ERRATUM.—This Journal, Aug. 15, 1918, page 452 A, col. 1, line 12 from top, after "Gregory" insert "Morrison."

I.—GENERAL ; PLANT ; MACHINERY.

PATENTS.

Evaporating and distilling apparatus [for water]. A. Duoda, Genoa, Italy. Eng. Pat. 111,480, Nov. 9, 1917. (Appl. No. 16,423 of 1917.) Under Int. Conv., Nov. 16, 1916.

THE apparatus consists of an evaporating box of trapeziform section with rounded corners, containing a nest of heating coils. The coils communicate with one another through headers, and are arranged to conform with the shape of the box. The coils extend above the level of the water in the evaporating box to superheat the steam.—J. H. P.

Rectifying and concentrating liquids; Apparatus for —. D. S. Monteith, Assignor to Chemical Construction Co., Charlotte, N.C. U.S. Pat. 1,271,349, July 2, 1918. Date of appl., Feb. 14, 1918.

THE acid or other liquid is fed down a tower into a concentrating chamber heated electrically. The concentrated liquid is run off from the chamber through a cooler and the hot gases and vapours given off pass away up the tower.—W. H. C.

Pulp-filter. T. L. Crane, Tyrone, N. Mex. U.S. Pat. 1,268,935, June 11, 1918. Date of appl., Apr. 5, 1917.

A ROTARY suction drum is supported on horizontal bearings in a casing, and a pair of circular members, supported by arms journaled in the same bearings, carry a number of angle-iron members having their apices adjacent to the drum to remove pulp from it. The circular members are oscillated by a crank and connecting rod.—W. F. F.

Filtering process. A. L. Genter, Assignor to The General Engineering Co., Salt Lake City, Utah. U.S. Pat. 1,269,700, June 18, 1918. Date of appl., Jan. 23, 1917.

THE mixture is continuously filtered and thickened and the filter medium cleansed *in situ* by utilising the current of the mixture in one chamber to collect the solids removed from the filter medium therein and convey them to the succeeding filter chamber.—W. H. C.

Centrifugal filtering and clarifying apparatus. O. E. Enell, Jersey City, N.J. U.S. Pat. 1,269,067, June 11, 1918. Date of appl., Oct. 12, 1916.

THE liquid to be filtered is introduced into a rotating bowl within which is a sleeve having openings communicating with the interior of the bowl. Filter frames are mounted on the sleeve and each frame has an inner receiving chamber. The base of the bowl has a number of removable partitions or baffles to retard the flow of liquid.—J. H. P.

Centrifugal dryer. F. B. Anderson, Assignor to C. O. and A. D. Anderson, Cleveland, Ohio. U.S. Pat. 1,271,112, July 2, 1918. Date of appl., Mar. 6, 1917.

A CONICAL screen mounted on a rotating horizontal shaft is surrounded by a casing. The material to be dried is fed into the smaller end of the screen and the dried material is arrested at the opposite end, whence it is continuously removed and discharged into a discharge spout in the casing. An off-take for water is also provided in the casing.—L. A. C.

Separator or clarifier; Centrifugal —. H. A. Riggs, Indianapolis, Ind. U.S. Pat. 1,271,367, July 2, 1918. Date of appl., May 3, 1916.

THE bowl of the separator is mounted on a hollow central tube which tapers upwards and is provided with a conical head-piece which is enclosed by a flanged and slotted feed-tube.—W. H. C.

Dryer. O. C. McCormick, Cleveland, Ohio, Assignor to J. E. Moyer, Akron, Ohio, S. K. Hine, Girard, Ohio, J. W. Wright, Youngstown, Ohio, and W. P. Canfield, Pittsburgh, Pa. U.S. Pat. 1,268,983, June 11, 1918. Date of appl., Sep. 9, 1916.

THE articles to be dried are carried on racks which are mounted on sprocket chains, and within the drying chamber is a series of sprocket wheels for receiving the chains. The chains pass alternately up and down from one end of the chamber to the other and also out through openings in the opposite end walls to allow of the racks being loaded and unloaded.—J. H. P.

Furnace. J. S. Tierney, Brooklyn, N.Y., Assignor to American Shop Equipment Co., Chicago, Ill. U.S. Pat. 1,269,132, June 11, 1918. Date of appl., Feb. 6, 1917.

TWO jets of air, one or both containing fuel, are injected at one end of a mixing chamber leading to a horizontal furnace chamber and are inclined so as to impinge on one another. An opening in the mixing chamber behind the jets is traversed by a bridge, the side walls of which converge towards the rear, so that fluid under pressure supplied through the opening is directed over the upper and lower surfaces of the mixing chamber.—W. F. F.

Furnace. W. S. Ralya, Assignor to A. H. Bohnstengel, Cincinnati, Ohio. U.S. Pat. 1,271,364, July 2, 1918. Date of appl., Dec. 9, 1915.

A FURNACE having an arched top is heated by the combustion of a regulated mixture of fluid fuel and air, which is introduced into the furnace at one side, and in such a manner that the products of combustion follow the curve of the arched top. The waste gas passes through passages below the furnace floor to the stack.—W. H. C.

Muffle. J. B. Farquhar, Vancouver, B.C. U.S. Pat. 1,269,270, June 11, 1918. Date of appl., Dec. 18, 1916.

A MUFFLE is constructed in two parts, one being an arched wall and roof member with an end wall formed integrally therewith, and the other comprising the floor and being provided with an "edge bead" to receive the bottom edge of the wall. The inner edge of the bead is bevelled outwards to provide a space at the outside of the wall, and this space is filled with a sealing material. The floor is recessed to receive the wall, the inner side of the recess having a vertical wall surface which bears against the lower end of the arched wall.—J. H. P.

Mixing dry lime with liquids; Process and apparatus for —. J. W. Adams and O. H. Egge, Spreckels, Cal. U.S. Pat. 1,269,994, June 18, 1918. Date of appl., Feb. 24, 1917.

THE liquid is contained in a vertical vessel provided with tubes, tube-plates, and a central well, similar to a vacuum evaporator. The liquid is caused to flow up the tubes and to return down the central well and the lime or other powdered material is distributed over the surface of the liquid as it flows towards the central well.—W. H. C.

Fire-extinguishing and fireproof composition. G. E. Ferguson, New York. Assignor to Pyrene Manufacturing Co. U.S. Pat. 1,271,506, July 2, 1918. Date of appl., Nov. 18, 1913.

THE composition consists of a mixture of substances which when exposed to heat gives off ammonia, and also produces a fireproof coating which serves to hold the ammonia about the burning material. A mixture of sodium silicate, borax, microcosmic salt, and monosodium phosphate is specified.—J. H. P.

Drying materials; Art of —. A. F. Wright, Newark, N.J., U.S.A. Eng. Pat. 117,704, Aug. 10, 1917. (Appl. No. 11,512 of 1917.)

SEE U.S. Pat. 1,251,317 of 1917; this J., 1918, 142A.

Utilisation and combustion of fuel. Eng. Pat. 117,637. See IIA.

Apparatus for treating gases with liquids. Eng. Pat. 117,843. See IIA.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Water-gas formation; Theory of —. Gwosdz. Z. angew. Chem., 1918, 31, 137–140.

EXPERIMENTS were made to ascertain the parts played in water-gas formation by the supposed primary reactions (1) $C + H_2O = CO + H_2$, and (2) $C + 2H_2O = CO_2 + 2H_2$, and the secondary reactions (3) $C + CO_2 = 2CO$, and (4) $CO + H_2O = CO_2 + H_2$. Superheated steam was passed over various forms of heated carbon and the composition of the issuing gases determined. The temperatures varied from 555° down to 560° C., and the speed of the current of steam was also varied. Natural forms of carbon containing ash in appreciable quantities behaved in a markedly different manner from purified carbon almost free from ash. With gas coke (8.5% ash) and wood charcoal (1.4% ash) a considerable proportion of carbon dioxide was always formed (up to 29%). On the other hand lamp carbon (0.1% ash) at temperatures down to 600° C. gave mixtures closely resembling water-gas as manufactured. Even at 560° C. the mixture:— CO_2 8.6%, CO 39.5%, H_2 40.0%, residue 11.9% was obtained. It is concluded that reaction (2) cannot be a primary reaction, because reaction (3) is known to be too sluggish to account for the formation of the high percentage of carbon monoxide found at these low temperatures. It is also concluded that reaction (1) is the primary reaction of water-gas formation, and that the carbon monoxide formed reacts with the excess of steam tending to establish the water-gas equilibrium, and that this reaction is catalytically influenced by the finely divided ash in the carbon.

Behaviour and detection of the smallest quantities of carbon monoxide in the chloride pipette. Hofmann and Schibsted. See XXIII.

PATENTS.

Fuel; Utilisation and combustion of —. G. Helps, Nuneaton. Eng. Pat. 117,637, Nov. 22, 1916. (Appl. No. 16,709 of 1916.)

A FURNACE heated by gas or vapour, e.g., a boiler

furnace, is provided with a series of parallel pipes arranged longitudinally round the cylindrical surface to be heated, and a combustible mixture is supplied to them. A number of burner heads are mounted along the pipes, adapted to give a coneless or nearly coneless flame as described in Eng. Pat. 111,495 (this J., 1918, 48 A) and thus cover the walls with a close film of flame. Additional longitudinal pipes with radial branches extending nearly to the cylindrical surface are provided for the supply of a regulated quantity of additional air. The system of pipes is mounted on a carriage moving on rails to facilitate removal. In a modification the furnace is provided with a firebrick filling, leaving a central longitudinal passage and a number of small longitudinal troughs in contact with the furnace wall. Burners are arranged at the inlets of the troughs to project a flame along the furnace wall, and additional air is fed through small radial passages leading from the central longitudinal passage to which the air is supplied. Alternatively, the firebrick device may be in the form of an arch supported on a wheeled carriage. The flame passages may be provided with spiral baffles or perforated discs to retard the hot gases. The combustion products may subsequently be passed through a feed-water heater.—W. F. F.

Coke-ovens; Apparatus for converting beehive-ovens into by-product —. B. Zwillinger, New York. U.S. Pat. 1,269,895, June 18, 1918. Date of appl., July 12, 1917.

EACH oven of a row of beehive coke-ovens is provided with a transverse combustion flue, divided laterally, and situated beneath but not communicating with the oven. The air for combustion is preheated by passing it through a heating passage in the setting below the floor in front of the ovens, and then through transverse conduits centrally below the oven to the combustion flue. Combustible gas is also supplied to the combustion flue adjacent to the hot air exit. The hot gases pass from the combustion flue through return flues beneath and towards the sides of the oven, and thence through a passage adjacent to the air heating passage. The by-products are withdrawn at the top of the oven.

—W. F. F.

Gas producer plant [for wood, etc.]. W. De C. Turner, Perth, Australia. Eng. Pat. 117,721, Sept. 11, 1917. (Appl. No. 13,041 of 1917.)

WOOD or other inferior fuel is fed into the producer by an endless conveyor operated by a hand wheel from a feeding chamber at the side, which is provided with an outer door and a communicating door so as to act as an air lock. The producer is lined with firebricks, those in one layer being hollow and connected by openings with the producer so as to act as a discharge conduit for the gas. The gas passes through a cooling and scrubbing chamber provided with baffles, and with a rotating wheel having a perforated periphery which breaks up the water supplied to the chamber. The gas passes through the wheel and then upwards through a vertical scrubber, where it meets a falling shower of water produced by a number of horizontal fans on a central vertical shaft, driven by water jets. The fan blades are constructed with upturned edges to divert the gas radially inwards to facilitate scrubbing, and with downturned flanges to receive the water jets. Each fan also carries a horizontal meshed disc through which the gas passes. The gas leaving the top of the scrubber passes upwards through a chamber containing filtering material, and thence to a storage chamber.—W. F. F.

Gas and phosphatic fertiliser material; Process of producing — A. F. Delacourt, Assignor to Soc. Anon. Ital. G. Ansaldo & Co., Genoa, Italy. U.S. Pat. 1,269,795, June 18, 1918. Date of appl. Apr. 11, 1918.

FUEL containing relatively large amounts of sulphides, e.g., lignite, is gasified in the presence of sufficient calcium phosphate to slag the ash and to unite with the bulk of the oxides of sulphur produced. The slag formed is suitable for use as a fertiliser.—L. A. C.

Gas-producers; Feeding mechanism for — C. W. Lummis, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pats. (a) 1,270,962 and (b) 1,270,963, July 2, 1918. Dates of appl., Mar. 10, 1916, and Oct. 12, 1915.

(A) THE fuel is fed from a hopper into a horizontal rotary cylinder having an opening on one side which connects alternately with the hopper and the producer as the cylinder is rotated. The cylinder works in a lower fixed cylindrical seating enclosing not more than half its circumference, so that it is freely movable away from the seating. The remaining surface of the rotating cylinder is partly covered by a yielding cylindrical section which is pressed against it by springs. The seating is gas-tight in all positions of the rotating cylinder. (B) In a feeding mechanism of the type described in (A), the yielding section is replaced by several longitudinal guiding plates which prevent the escape of fuel past the opening in the rotary cylinder as it passes through the upper part of its movement towards the fixed seating.—W. F. F.

Gases; Method of and means for storing — F. C. Short and F. W. Moore, Walsall. Eng. Pat. 117,842. (Appl. Nos. 11,001, July 31, and 12,444, Aug. 30, 1917.)

BROKEN or powdered charcoal, preferably that obtained from coconut shells, is impregnated with a metal such as platinum, gold, palladium, iron, nickel, or cobalt, by impregnating with a suitable salt and then reducing the salt to deposit the metal in finely divided form. The product is used in a storage container as an absorbent for gases such as coal gas.—W. F. F.

Gases; Apparatus for treating — with liquids. N. Wilton, and The Chemical Engineering and Wilton's Patent Furnace Co., Ltd., Hendon, Middlesex. Eng. Pat. 117,843, July 31, 1917. (Appl. No. 11,039 of 1917.)

GAS, e.g., coal gas which is to be treated with water to extract ammonia, or with oil to extract benzol, is passed through a chamber divided by parallel vertical partitions into a number of compartments connected by openings near the top of the partitions. Supplementary partitions extend midway through each compartment from the top downwards for two-thirds of the height, so that the gas takes a zigzag path. That section of each compartment through which the gas flows downwards is provided with a number of contact surfaces, such as bundles of wooden boards, which are kept coated with liquid distributed by a perforated plate above. The washed gas passes under the supplementary partition and upwards through the adjoining passage to the next compartment, so that it always flows over the contact surfaces in the same direction as the liquid. The liquid passes through the casing in a general direction opposite to that of the gas, the bottom of all the compartments being connected by pipes to maintain a predetermined level. The liquid in each compartment is withdrawn by an "air-lift" pump below, and raised to a perforated

spraying pipe at the top, so that the proportion of absorbed gas in the liquid increases as the liquid passes towards the gas inlet end of the casing. The pumps are preferably operated by a portion of the gas which has passed through the apparatus and has been compressed to the necessary pressure.

—W. F. F.

Fuel for use in explosion engines. L. Solari, Turin, Italy. Eng. Pat. 109,802, Sep. 3, 1917. (Appl. No. 12,625 of 1917.) Under Int. Conv., Feb. 26, 1916.

THE fuel consists of a mixture of alcohol, free or nearly free from water, and petrol. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 2515 of 1914 and 18,468 of 1907; this J., 1915, 948.)

—W. F. F.

Liquid fuel. A. A. Backhaus, Baltimore, Md., Assignor to U.S. Industrial Alcohol Co. U.S. Pats. (a) 1,271,114 and (b) 1,271,115, July 2, 1918. Date of appl., Oct. 12, 1917.

A LIQUID fuel is composed of a petroleum distillate (gasoline, kerosene), an alcohol (ethyl alcohol), and (a) an aromatic nitro-compound (nitrobenzene) or (b) a phenol (cresol).—L. A. C.

Crude petroleum and natural gas separator. M. J. Trumble, Assignor to F. M. Townsend and A. J. Gutzler, Los Angeles, Cal. U.S. Pat. 1,269,134, June 11, 1918. Date of appl., Nov. 14, 1914.

Oil and gas are passed through a pipe, provided with a heating jacket and containing a device for reducing velocity, to the top of a vertical cylindrical expansion chamber. The heating fluid passes also through a coil in the bottom of the expansion chamber. The oil is distributed over the surface of the chamber by a spreading cone carried by the lower end of a pipe passing upwards concentrically through the oil inlet aperture and provided with a valve for withdrawing gas at a regulated pressure. The oil collects at the bottom of the chamber and is withdrawn through a pipe, the inlet of which is kept submerged in the oil by a float valve, which controls the liquid level by regulating the discharge.

—W. F. F.

Oil-shale; Method of and apparatus for treating — [in situ]. L. H. Rogers, New York. U.S. Pat. 1,269,747, June 18, 1918. Date of appl., Apr. 6, 1918.

PORTIONS of an oil-shale bed are removed, leaving columns of the shale undisturbed. An impervious wall is built around each column, being spaced therefrom and having a metal lining. Means are provided for supplying heat for distillation of the shale in these columns and for the removal of the products.—L. A. C.

Petroleum product and process of making the same. R. de M. Taveau, Assignor to The Atlantic Refining Co., Philadelphia, Pa. U.S. Pat. 1,271,387, July 2, 1918. Date of appl., July 6, 1914.

THE acid sludge resulting from the treatment of petroleum or petroleum products with concentrated sulphuric acid is agitated with water in the presence of sufficient alkali to neutralise the free sulphuric acid and all or a part of the sulphonic acid content. The water-soluble sulphonates form an emulsifying agent and the resulting emulsion is heated below the emulsion-breaking temperature. The emulsion is then "broken" and allowed to separate into layers containing respectively asphaltic material and sulphonates in solution.—L. A. C.

Process of making high-percentage calcium carbide.

PATENTS.

Destructive distillation; Processes of —. C. Turner, Manchester. Eng. Pat. 117,645. (Appl. Nos. 8743, June 18, and 17,298, Nov. 23, 1917.)

CARBONACEOUS material, such as peat, lignite, oil shale, oil-impregnated material, or coal, is subjected to destructive distillation in a vessel in which the pressure is raised until it has attained a desired maximum and then reduced rapidly, the operations being repeated until distillation is complete. The retort may be heated externally, but, preferably, superheated steam or heated inactive gas is passed into it. The products pass out of the retort during the reduction of pressure and are condensed. For example, a cylindrical iron container $2\frac{1}{2}$ ft. in diameter and 7 ft. high is connected at the bottom through a stop valve with a boiler generating steam at 20 lb. pressure, and at the top through a similar valve with a condensing plant. The container is charged with air-dried peat and steam blown through to expel the air. The outlet valve is then closed, and steam, superheated to about 500° C., passed in until the pressure is 5 lb. per sq. in.; the inlet valve is then closed and the outlet valve opened until the pressure falls to 2 lb. per sq. in. The operations are repeated until there is no further distillation of products.—L. A. C.

Wood-gas regulating valve; Automatic — for destructive wood distillation plants. R. A. and W. Cooper, East Smethport, Pa. U.S. Pat. 1,269,392, June 11, 1918. Date of appl., June 10, 1916. Renewed Jan. 12, 1918.

BRANCH pipes fitted with fluid-controlled dampers connect a main gas pipe, which is connected with a boiler, to each condenser of a battery of retorts and condensers for wood distillation. The main gas pipe is kept under suction.—L. A. C.

Destructively distilling wood; Method of —. R. C. Palmer, Pensacola, Fla., Assignor to the Government and people of the United States. U.S. Pat. 1,271,071, July 2, 1918. Date of appl., Mar. 23, 1917. (Dedicated to the public.)

A SUITABLE amount of water is added to wood tar, wood tar pitch, or any of the fractions of crude wood tar, and the mixture distilled under pressure or in the presence of a chemical catalyst, e.g., phosphoric acid. Methyl alcohol, acetic acid, acid phenols, and tar oils are recovered from the condensed vapours. Mixtures of wood with wood tar are distilled at a temperature necessary to carbonise the wood, the vapours confined in the retort under pressure, then released and condensed.

—L. A. C.

Cathode device; Incandescent —. G. S. Meikle, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,267,888, May 28, 1918. Date of appl., Aug. 15, 1916.

A SEALED container is provided with a filling of neutral gas, together with a quantity of iodine, and with co-operating electrodes, at least one of which is adapted to operate at incandescence.

—B. N.

III.—TAR AND TAR PRODUCTS.

Hydrogenation of aromatic compounds with the help of platinum. III. Hydrogenation with platinum containing oxygen. Willstätter and Jaquet. See XX.

IV.—COLOURING MATTERS AND DYES.

Colouring matters; Isolation of — by means of picric and dichloropicric acids. R. Willstätter and G. Schudel. Ber., 1918, 51, 782—788.

IN his work on anthocyanins, Willstätter has already achieved a certain measure of success in the isolation of the colouring matters by a process which depends on their partition between water and amyl alcohol (compare this J., 1916, 300). By this method, however, only non-glucosidic colouring matters are efficiently extracted, diglucosides often being left entirely in the aqueous layer. A wider range of colouring matters can be extracted as picrates if picric acid is added to the solution, especially if a mixture of amyl alcohol and acetophenone (2 : 1) is used as the medium. Unfortunately the picrates of these colouring matters are usually not very soluble in organic media. Dichloropicric acid is much superior in this respect, and, by the use of this acid, rosaniline, pararosaniline, and Methylene Blue can be completely extracted from aqueous solutions by ether, Safranine by diethylketone, and mono- and di-glucosidic colouring matters can be removed completely by one extraction with the above amyl alcohol-acetophenone mixture. The preparation of dichloropicric acid is described. (See further J. Chem. Soc., 1918, 1, 399.)—J. C. W.

Phenonaphthacridonequinone and quinacridonequinone; The linear —. W. St. Leśniański. Ber., 1918, 51, 695—706.

THESE quinones, represented by the formulae,

respectively, have been synthesised in order to determine whether quinones of the acridone series have the properties of vat dyes. Phenonaphthacridonequinone sublimes in orange needles, m.p. 384° C., and forms a blue alkaline-hydrosulphite vat from which cotton is dyed orange-yellow, and

quinacridonequinone, a refractory yellow powder, is also reducible, but the bluish-violet product is insoluble, and therefore not applicable as a dye. (See further J. Chem. Soc., 1918, I., 405.)

—J. C. W.

Dyestuffs derived from *m*-phenetidine. F. Reverdin, A. Rilliet, and C. Vernet. Arch. Sci. phys. nat., 1918, 46, 74—80.

***m*-PHENETIDINE** when coupled with diazobenzene chloride yielded benzeneazo-*m*-phenetidine, m.p. 84°—85° C. This base when further diazotised and coupled with β -naphthol gave the insoluble disazo compound, $C_6H_5N : N \cdot C_6H_4(OC_6H_5)_2N : N \cdot C_{10}H_7(OH)$. Benzeneazo-*m*-phenetidine was diazotised and coupled with the following compounds giving dyestuffs, the dyeing properties of which are given in brackets:—with R salt (reddish-violet on silk, duller on wool, not fast to washing); with naphthionic acid (reddish-brown on silk, not fast to light); with γ -acid, 2,8,6-aminonaphtholsulphonic acid (violet-brown on wool); with chromotrope acid, 1,8-dihydroxynaphthalene-3,6-disulphonic acid (bluish-violet on ordinary wool, greyish-blue on chrome-mordanted wool); with R-acid, 2,3,6-naphtholdisulphonic acid (brownish-red on ordinary wool, giving a chrome lake); with β -naphthol-7-sulphonic acid (violet-red, moderately sharp, on wool); with α -naphthol-4-sulphonic acid; with H-acid, 1-amino-8-naphthol-3,6-disulphonic acid (brownish-violet on wool). All of these colours are devoid of special qualities which might give them a technical interest, although some of them, from the point of view of shade and tinctorial properties and leaving cost out of count, could rival some of the colours used industrially. *m*-Sulphanilic acid when diazotised and coupled with *m*-phenetidine yielded *m*-sulphobenzeneazo-*m*-phenetidine, reddish brown needles, m.p. 214°—215° C., which when further diazotised gave a diazo derivative, only slightly soluble and very stable, which was coupled with *p*-nitrobenzeneazo-8-amino- α -naphthol-3,6-disulphonic acid, giving the trisazo compound, $SO_3H \cdot C_6H_4N : N \cdot C_6H_4(OC_6H_5)_2N : N \cdot C_{10}H_7(OH)(NH_2)(SO_3)_2N : N \cdot C_6H_4NO_2$, a blackish-green powder, dyeing wool bluish-green at 1%, deep bluish-green at 3%, bluish-green almost black at 5%, and black at 8.5%. These tints are moderately fast to potting and falling, and the shade is scarcely modified by chrome-mordanting. When *p*-nitraniline was diazotised and coupled with *m*-phenetidine it gave *p*-nitrobenzeneazo-*m*-phenetidine, which without being isolated was further diazotised and coupled in alkaline solution with chromotrope acid giving the compound, $NO_2 \cdot C_6H_4N : N \cdot C_6H_4(OC_6H_5)_2N : N \cdot C_{10}H_7(OH)(SO_3H)_2$, a brownish-black powder, dyeing wool a dull violet. If the nitro group of the *p*-nitraniline nucleus in this compound is reduced by sodium sulphide (Meister, Lucius, u. Brüning, 1892, Ger. Pat. 91,283; Friedländer, 4, 725) a brown compound is obtained, which dyes wool blue.—W. G.

Fisetol; Attempt to synthesise — J. Tambor and E. M. Du Bois. Ber., 1918, 51, 748—751.

ω -BROMO-2-HYDROXY-4-METHOXYACETOPHENONE, from *m*-dimethoxybenzene and bromoacetyl bromide, is heated with sodium acetate and acetic anhydride, when the diacetate of ω -2-dihydroxy-4-methoxyacetophenone, $HIO \cdot C_6H_3(OC_2H_5)_2CO \cdot CH_2 \cdot OH$, is formed. The latter is the methyl ether of fisetol, but has not yet been demethylated. (See further J. Chem. Soc., 1918, I., 395.)—J. C. W.

PATENTS.

Lignonsulphonic acid or its salts; Method of preparing azo colouring matters from —. E. Oman, Stockholm, Sweden. Eng. Pat. 103,480, Jan. 4, 1917. (Appl. No. 200 of 1917.) Under Int. Conv., Jan. 20, 1916.

ISOLATED lignonsulphonic acid or the solution of its salts prepared by precipitating the ligninsulphonates from sulphite-cellulose waste liquor by sodium chloride and concentrating the filtrate to one-fifth of its bulk, is coupled with diazotised aromatic amines, e.g., aniline or 4-nitro-2-toluidine, and the azo compound, varying in colour from light red to dark brown, is precipitated by the addition of alcohol or a salt.—J. F. B.

[Indigoid] vat dyes; Yellowish-brown — W. Bauer and A. Herre, Opladen, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pat. 1,266,092, May 14, 1918. Date of appl., Mar. 23, 1915.

A CLAIM for vat-dyes of the type.

in which the benzene nucleus I does, and nucleus II may, contain halogen, and R may be oxygen or hydrogen. The compound obtained by combining 5,7-dichloroisatin with 6-aminoindoxyl is specially mentioned; it is a dark brown, lustrous, crystalline powder, soluble in concentrated sulphuric acid with reddish-violet colour, which dyes cotton from the hydrosulphite vat in yellowish-brown shades, fast to light, washing, and chlorine.—J. C. W.

Process for the manufacture of inks for printing on paper. Eng. Pat. 117,023. See XIII.

[Indelible] writing inks. Eng. Pat. 117,117. See XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Woollen fabric; Determination of acid in —. A. Woodmansey. J. Soc. Dyers and Col., 1918, 34, 172—175.

The determination of small quantities of acid in wool is complicated by the strong affinity between the fibre and the acid, which makes it extremely difficult to extract the latter by simple washing. A method has been devised based on the principle of distribution of the acid between two immiscible solvents, the wool being one and the aqueous portion the other. The indicator employed is a solution of Methyl Red in dilute alcohol (0.5 gm. per litre). This indicator, when spotted on the cloth, shows a distinct indication only when the cloth has been treated and dried with 0.2% of sulphuric acid, proving that wool itself is essentially alkaline. For the determination of acid in a sample of woollen cloth, standard curves must first be established for a similar cloth which is neutral and has been treated with known quantities of acid. Pieces of the neutral cloth, 10 grms. each, are steeped in 300 c.c. each of solutions made up with increasing quantities of standard sulphuric acid. After standing overnight to attain equilibrium, 250 c.c. is withdrawn and titrated. The curves are plotted with total acid as ordinates and acidity of 250 c.c. of aqueous solution as abscissae. Similar determinations are carried out with the sample to be tested, three pieces being taken, one with water and two with known quantities of the same acid. By superposing the curve of the sample on the curve of the

standard, the equivalent of acid already present in the former is found by difference. If the "net" acidity be desired, it is necessary to determine the amount of acid required to neutralise the wool and deduct this from the total value found. If the quantity of sample available is only small, the data for the curve may be obtained from one piece with successive additions of acid.—J. F. B.

Cellulose and its derivatives; The fluorescence of — S. J. Lewis. J. Soc. Dyers and Col., 1918, 34, 167–172.

It had previously been recorded by Hartley (Chem. Soc. Trans., 1893, 215) that cellulose in the form of white blotting paper is fluorescent and capable of rendering visible the whole of the ultraviolet spectrum as far as wave-length 2000. This phenomenon has been studied by the author, and the effects have been recorded photographically to show the relative intensity of the degradation of ultraviolet light at various wave lengths to visible rays capable of passing through glass and affecting the photographic plate. Graphs have been constructed in which the intensities are plotted as ordinates and the wave-lengths as abscissae. The general results show that the power and distribution of the fluorescent properties are definite functions of the chemical constitution, and their variations conform to what is known of the influence of substituent groups on the properties of the original substance. Normal cellulose, from whatever source it is derived, gives a fairly uniform spectrum, but the intensity varies with the specimen under observation. The cellulose from rhubarb stalk and cuticle falls in the same group. Modified celluloses, such as viscose fabric and parchmentised paper, show a considerable divergence from the normal; well beaten "bank" paper falls in the same class, which is characterised by a strong effect at a wave-length of 2750. Ground wood paper (lignocellulose) is devoid of fluorescent properties, and the cellulose nitrates are nearly, if not quite, inactive. On the other hand, the acetylcelluloses exhibit a fluorescence which is generally much stronger than that of the normal cellulose, and which is much stronger towards the visible region than towards the extreme ultraviolet. For media of the same chemical constitution the resulting degraded spectrum is much the same for the transparent film through which the ultraviolet light is transmitted as for the opaque network in which it is reflected at the surface of the fibres.—J. F. B.

Artificial silk; The formation of the thread in the spinning of — H. Ost. Z. angew. Chem., 1918, 31, 141–144.

CUPRAMMONIUM solutions are spun from groups of single glass capillary jets, 0.2–0.16 mm. wide and 1–4 mm. long in the capillary. Viscose is spun from platinum discs pierced with 15–25 holes of 0.10 mm. diam. The spinning pressure is 1.5–2.5 atmos. in both cases. At the Elberfeld works the cuprammonium is prepared by blowing air through aqueous ammonia in presence of metallic copper at a low temperature, the cotton being subsequently introduced. The spinning solution contains 7–8% cellulose, 2.5–3% Cu, and 7–8% NH_4 , together with some sucrose and other additions; the solution is strained several times through the finest steel wire cloth. Viscosity is determined in a tube, 32 mm. wide, 280 mm. long, with marks indicating a volume of 150 c.c.; the tube terminates in a short orifice, 5 mm. wide. A suitable solution runs out in 5–6 mins., and falls in a continuous thread 2 m. long before breaking up into drops. A coagulating bath containing 33 grms. of caustic soda and 8 grms. of sugar per 100 c.c. is generally used, at 48°–50° C.; sulphuric acid containing 32–50 grms. per 100 c.c.

behaves similarly, but the threads are not so good. In practical spinning finer jets than those mentioned are not satisfactory, owing to clogging, and the fineness of the thread is controlled by "drawing out." Fine threads can be spun from coarse jets and coarse threads from fine jets, depending on the relation between the speed of drawing and the supply of cellulose solution; this latter depends on the pressure of delivery and the internal resistance of the capillary, i.e. its length and fineness. There is a limit to the extent to which the diameter may be reduced by drawing out, owing to the breaking of the thread by the increased frictional resistance. The maximum effect obtained in practice represents an extension of the filament to 5–6 times its original length. The diameter of the threads spun from 0.2 mm. capillaries under practical conditions is about 0.1 mm. wet and 0.03 mm. after drying. Much finer threads are spun by the Thiele-Bemberg system, with diameters down to 10–15 μ , approximating to that of natural silk. In this system capillaries are not used, the fluid being delivered from orifices of 0.8 mm. into a long column (500 mm.) of a very weak coagulating bath, e.g. a 2% solution of caustic soda for cuprammonium. Owing to the slow action of the coagulating bath the thread remains plastic for a considerable time, and is drawn out to a very fine diameter before it is finally solidified. With the capillary process and concentrated coagulating baths the thread is immediately solidified, and its final diameter is fixed as soon as it comes in contact with the liquid of the bath. Experiments are described showing the nature of the formation of the thread in spinning cuprammonium solutions from glass capillaries. With a capillary 0.2 mm. wide and 3.5 mm. long, a pressure equivalent to 1000 mm. of mercury and a drawing speed of 6.5 m. per min. give a thread of 0.2 mm. diam., i.e. equal to the diameter of the jet; complete coagulation takes place in this case immediately at the orifice of the jet. When the drawing speed is increased to 44 m. per min., which is normal practice for these conditions, the thread is drawn out to a diameter of 0.10 mm., but this reduction takes place some distance up the capillary where the solution is perfectly fluid, and the coagulating liquid enters the mouth of the capillary. With a capillary 6.5 mm. long, the point of reduction is shifted still higher up owing to the reduced supply caused by increased frictional resistance, and if the delivery pressure is not increased the speed of drawing must be decreased to 34 m. per min. to avoid breaking the thread: the diameter of the thread is then 0.12 mm. With a shorter capillary, 1.5 mm. long, under the same pressure, the supply is considerably greater, and the speed of drawing can be increased to 80 m. per min., giving a thread 0.09 mm. in diameter; in this case the capillary is practically filled and the point of reduction is situated at the orifice. A jet 1.0 mm. long, but 0.16 mm. wide, permits a drawing speed of 85 m. per min., but the point of reduction is visibly inside the capillary; the thread has a diameter of 0.10 mm. When a thread breaks, the drawing tension is nil and the thread issuing under pressure has a diameter larger than that of the capillary. A thread of 0.22 mm. diameter can be spun from a capillary of 0.20 mm. if the jet be very short (1.0 mm.) and the drawing speed low (9 m. per min.). With a very short jet, a very high drawing speed (88 m. per min.) may exert a pull right up the capillary, so that the thread is drawn from the wide portion of the jet and occupies only about half the bore of the capillary.—J. F. B.

Waterproofed canvas; Manufacture of — E. R. Clark. India Rubber J., 1918, 56, 175–176.

WATERPROOFED canvas for military purposes must retain its waterproof qualities under extremes of

temperature and in spite of rough usage. It is important that it should be resistant to mildew. The samples examined by the author are classified as manufactured by processes involving the use of the following:—(1) aluminium soaps; (2) asphaltum, paraffin, pitch, etc.; (3) cellulose dissolved in cuprammonium solution and other forms of dissolved cellulose; (4) drying oils; (5) two layers of fabric with an intermediate adhesive layer. (1) Basic aluminium acetate and saponified linseed oil yield a specially durable product. The fabrics have a good water-repellent surface, but do not stand rough handling well. (2) Asphaltum is a good material for the purpose. Disadvantages of paraffin are that it tends to become brittle, and to favour the growth of mildew. Rosin and wool grease are unsatisfactory admixtures. A solution of rubber in melted paraffin gives good results. (3) Objections to this process are that it is expensive, and that the fabrics are harsh, and are liable to give off an irritant dust when handled. They strongly resist the growth of mildew. (4) These fabrics are liable to spontaneous combustion, and almost invariably crack as the result of repeated creasing. (5) The middle layer of double fabrics must be possessed of good waterproofing and lasting properties. Poor rubber, for example, is of no value. In examining samples the following points should be taken into consideration:—The sample when held to the light should show no pin-holes, reed-marks, or badly-coated patches. It should not be greasy or very stiff, nor have an objectionable odour. The coating should not rub off nor crack on sharp creasing. The colour should be satisfactory. For testing the waterproof quality, the sample is stretched over the mouth of a bottle and a spray of water (*e.g.*, from a Gooch crucible) allowed to fall on it from a height. The time which elapses before the first drop passes through, and the amount passing through in a given time are noted; or, the material is folded into a pocket which is then filled with heavy articles and immersed in water. A good fabric should not wet through in 24 hours. Samples should not develop mildew growths in 5 days when suspended in a desiccator containing a variety of such growths. The effect of temperatures of 0° F. (–18° C.) and 120° F. (49° C.) for eight hours upon the waterproof quality of samples should be determined. A chemical examination should also be made.—E. W. L.

PATENTS.

Drying apparatus [for fibrous materials]. A. Hirth, Stuttgart-Cannstadt, Germany. U.S. Pat. 1,266,946, May 21, 1918. Date of appl., June 24, 1915.

Is an apparatus for suspending and drying strands of material, a number of arms are provided with means for feeding strands to the arms, means for presenting the feeder to alternate sides of each arm and displacing it lengthwise of the arms.

—J. F. B.

Coated fabrics; Apparatus for treating —. W. P. Egan and J. J. Sheehan, Lynn, Mass. U.S. Pat. 1,268,941, June 11, 1918. Date of appl., May 7, 1917.

A STEAM chamber is provided with a perforated wall over which a coated fabric moves while moist steam passes through it. The steam is supplied by a number of perforated pipes extending the length of the chamber, and heat is also radiated into the chamber from a steam pipe inclined upwards into the chamber, but substantially closed at its inner end.—W. F. F.

Silk, silk waste, and the like; Process of degumming —. K. Tanaka, Nakashima Gun, Japan. U.S. Pat. 1,268,513, June 4, 1918. Date of appl., Dec. 8, 1916.

SILK is treated with a degumming fluid, *e.g.* a solution of soap and sodium bicarbonate, the liquid being heated by steam under a pressure of 15–20 lb.

—J. F. B.

Wood pulp; Manufacture of —. O. Kress and S. D. Wells, Madison, Wis. U.S. Pat. 1,266,957, May 21, 1918. Date of appl., Dec. 10, 1915. (Dedicated to the public.)

Wood is impregnated with an alkaline digestion liquor at about 185° F. (85° C.) under pressure; the pressure is reduced before digestion takes place, and the excess of the alkaline liquor is removed. This is cooled and the rosin soap is skimmed off. The wood impregnated with liquor is digested with steam, and the foaming rosin soap, distilled turpentine and other volatile oils produced in the digestion of the wood are collected.—J. F. B.

Paper pulp; Manufacture of —. S. D. Wells, Madison, Wis. Dedicated to the Government and people of the U.S.A. U.S. Pat. 1,268,193, June 4, 1918. Date of appl., April 2, 1918. (Dedicated to the public.)

Wood or other fibrous material for the production of paper pulp is digested by a liquor in which the concentration of active chemicals during the digestion is reduced to the desired degree by the introduction of spent lye while the digestion is proceeding, whereby the cellulose is protected to a marked degree from the action of the digestion liquors, while their action on the incrusting matters is not diminished.—J. F. B.

Paper-making machine. J. Galipeau, Assignor to J. H. Garth, Montreal, Canada. U.S. Pat. 1,266,673, May 21, 1918. Date of appl., May 12, 1917.

THE travelling screen of the paper machine is provided with a suction-box which acts upon the screen and has its suction connection at one end, and means, combined with the suction connection, whereby the box is reciprocated across the direction of travel of the screen.—J. F. B.

Paper; Waterproof composition for coating — and process of making same. B. Kniller, Winchester, Mass. Assignor to Vera Chemical Co., Stoneham, Mass. U.S. Pat. 1,266,955 and 1,266,956, May 21, 1918. Date of appl., Nov. 22, 1913.

THE coating emulsion consists of a mixture of paraffin wax, ammonium stearate, and sufficient water to form a viscous mass with the quantity of ammonium soap employed. It is prepared by adding ammonia to a fatty acid to form an ammonium soap in presence of paraffin wax, heating the mixture and adding sufficient water to form a viscous emulsion, which is subsequently diluted with water.—J. F. B.

Sulphite-cellulose manufacture; Process of dissociating waste lye from —. I. Sörras, Hardanger, Norway. U.S. Pat. 1,268,774, June 4, 1918. Date of appl., Mar. 27, 1918.

SULPHITE-CELLULOSE waste lye is heated to a temperature not materially below 80° C. while confined in an atmosphere of a non-oxidising gas; it is then heated in a second operation to about 100° C. in the presence of an oxidising gas under pressure

until the lignin is precipitated. This second heating is performed while introducing compressed air into the liquid, whereby the oxygen in the air is considerably reduced, and the exhaust gas of the second operation is conveyed to the containers in which the first heating is carried out, serving as the non-oxidising atmosphere.—J. F. B.

Beating machines for making pulp for paper manufacture. S. Heys, Birmingham. Eng. Pat. 117,880, Dec. 22, 1917. (Appl. No. 18,997 of 1917.)

Method of preparing azo colouring matters from lignansulphonic acid or its salts. Eng. Pat. 103,480. See IV.

Case-hardening material. U.S. Pat. 1,270,874. See X.

Process for the manufacture of inks for printing on paper. Eng. Pat. 117,023. See XIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Dyeing; Composition for use in —. J. W. Fries, Winston-Salem, N.C. U.S. Pat. 1,266,577, May 21, 1918. Date of appl., June 16, 1915.

A dry powdered composition for use in dyeing cotton goods is composed of a mixture of a vegetable dye extract, such as logwood, and an ammoniacal hydrated metallic oxide, such as copper oxide. A mixture of a non-alkaline metallic salt, e.g., a copper salt, and an alkaline salt is treated with sufficient ammonia solution to prevent a precipitate being formed, and this liquid is mixed with the vegetable dye extract to form a thick paste, which is finally dried.—J. F. B.

Dyeing wool and other fibrous substances; Apparatus for —. F. Geissler, Cottbus, Germany. U.S. Pat. 1,267,209, May 21, 1918. Date of appl., Aug. 14, 1916.

The apparatus consists of a box adapted to the shape of yarn dyeing machines, both the lid and one side of the box being removable and guided in grooves in the box, and the lid, when in position, overlapping the upper edge of the removable side.

—J. F. B.

Skein-dyeing machine. H. Dudley, Philadelphia, Pa. U.S. Pat. 1,268,441, June 4, 1918. Date of appl., June 28, 1917.

The apparatus consists of a dyeing chamber, a skein-carrying frame within the dyeing chamber, foraminous plates below and above the skein-carrying frame, a series of tubular members abutting on the outer face of each of the foraminous plates, whereby liquid may be passed in either direction through the foraminous plates and the dyeing chamber. A second dyeing chamber is provided adjacent to the first, also containing a fibre-carrying frame, and the top and bottom portions of the second chamber are connected respectively with the top and bottom portions of the first.—J. F. B.

Dyeing process. F. J. Oakes and S. O. Dillon, New York. U.S. Pat. 1,271,067, July 2, 1918. Date of appl., July 2, 1915.

For dyeing vegetable fibres (e.g., cotton) a lake is produced by adding the colouring matter to a bath

containing a salt of a heavy metal (copper sulphate) and an alkali (sodium carbonate). The lake is then dissolved in a hot acid solution (acetic acid), in the presence of a neutral salt (sodium sulphate), and the material to be dyed immersed in the solution.—L. A. C.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Polash salts in Hungary. F. von Konek-Norwall. Chem.-Zeit., 1918, 42, 365–367.

LARGE quantities of alunite occur in Northern Hungary. The potassium sulphate may be recovered by roasting at a red heat until all the aluminium sulphate has been decomposed and sulphuric acid fumes are no longer evolved. The residual mass consists of potassium sulphate (14 to 15%), alumina, and frequently a considerable quantity of silica; it forms a white powder and may be used directly on the land, but when it has to be transported for a distance it is more economical to extract it with water and separate the potassium sulphate by crystallisation from the solution. The mixture of alumina and silica may be used in the manufacture of porcelain, or the alumina converted into alum for use in the textile trades, the sulphuric acid for making the alum being obtained by condensing the vapours which are given off when the original mineral is roasted.—W. P. S.

Alumina; Production of — in the aluminium industry, with special reference to the rotary kiln. W. von Escher. Chem.-Zeit., 1918, 42, 361–362. (See also this J., 1918, 504 A.)

A type of rotary kiln specially adapted to drying and dehydrating aluminium hydroxide containing 45–50% total H₂O is described. Owing to the high temperature required, 1500°–1550° C., the kiln differs considerably from the type used in the cement industry. It consists essentially of five parts, a feeding device, the kiln proper, a cooler for the hot alumina, an automatic device for weighing and delivering the product into sacks, and a dust-collecting equipment for recovering dust from the escaping gases. The kiln is fired with producer or natural gas, the air being preheated and supplied under pressure. The losses are very small, under 1%. The dehydrated alumina should have a loss on ignition of at most 0.15%.—E. H. R.

Hydroxides; Solubility of some metallic — in water. G. Almkvist. Z. anorg. Chem., 1918, 103, 240–242.

The following solubilities have been determined, using ordinary distilled water at 20° C.:—Ni(OH)₂, 12.7 mgrms. per litre; Co(OH)₂, 3.18; Bi(OH)₃, 1.44; Fe(OH)₃, 0.151; MnO(OH)₂, 0.43 mgrms. per litre. (See also J. Chem. Soc., 1918, ii., 320.)

—E. H. R.

Vanadic acid; Application of rapidly rotating metallic reductors in the determination of —. F. A. Gooch and W. Scott. Amer. J. Sci., 1918, 48, 427–436.

The reduction of vanadic acid may be effected rapidly in the presence of sulphuric acid by means of rapidly rotating electrodes of copper or silver, or by a rotating cylinder of zinc without the use of the electric current. The following procedure is recommended, as the volume and temperature of the solution and the relative size and speed of rotation of the zinc cylinder affect the rapidity of the reduction:—Volume of

solution at outset, heated to boiling, 80 c.c.; 5 c.c. of concentrated sulphuric acid; diam. of cylinder, 2 cm.; surface of cylinder exposed to action, 25 sq. cm.; speed of rotation, 850 r.p.m. At the end of the reduction, the solution is diluted to 250 c.c. and 10 c.c. of a saturated solution of silver sulphate added to ensure all the vanadium being in the form of tetroxide; the solution is then boiled to coagulate the precipitated silver, filtered, again heated to boiling, and titrated with standard potassium permanganate. A correction, as determined in a blank test, must be applied. (See also J. Chem. Soc., Oct., 1918.)—A. B. S.

PATENTS.

Sodium carbonate and ammonium sulphate; Manufacture of — from bisulphate of soda. Soc. Industrielle de Produits Chimiques, Paris. Eng. Pat. 109,814, Sep. 19, 1917. (Appl. No. 13,487 of 1917.) Under Int. Conv., Sep. 20, 1916.

NITRE cake is treated with water and sufficient ammonia to neutralise the free acid and an excess according to the quantity of sodium sulphate present. The mixture is heated and treated with carbon dioxide under slight pressure with formation of ammonium bicarbonate, which by double decomposition with a portion of the sodium sulphate forms ammonium sulphate and sodium bicarbonate, the latter precipitating out. The mother liquors after neutralisation with nitre cake are fractionally crystallised to separate sodium and ammonium sulphates and the sodium sulphate is used in a fresh charge.—C. A. K.

Reduction; Process of [producing barium sulphide by] electrical —. C. H. Fulton, St. Louis, Mo., Assignor to Metallurgical Laboratories, Inc., Chicago, Ill. U.S. Pat. 1,267,317, May 21, 1918. Date of appl., July 25, 1917.

Barium sulphide is produced by mixing approximately 100 parts of finely-divided barium sulphate (barytes) with 70 to 85 parts of finely crushed coke and 20 parts of a carbonaceous binding material, the coke acting as a conductor of electricity as well as a reducing agent. The mixture is formed into

briquettes, retaining approximately their original form after being subjected to a temperature high enough to bring about the desired reduction. A current of electricity is passed through one or more of the briquettes, whilst they are confined in an electric reduction furnace and in engagement with the electrodes of the furnace. The briquettes are subsequently treated with water to dissolve out the barium sulphide.—B. N.

Alumina; Producing crystalline —. R. H. White, Niagara Falls, N.Y., Assignor to Norton Co., Worcester, Mass. U.S. Pat. 1,269,141, June 11, 1918. Date of appl., Aug. 18, 1917.

The method consists of electrically fusing in a carbon hearth furnace a non-uniform charge of which the lower portion contains an oxidising addition yielding volatile reduction products, whereby reduction of alumina by the carbon hearth is prevented.—J. H. P.

Aluminous materials; Purifying —. L. E. Saunders, Niagara Falls, N.Y., Assignor to Norton Co., Worcester, Mass. U.S. Pats. (A) 1,269,223 and (B) 1,269,224, June 11, 1918. Date of appl., Aug. 18, 1917.

(A) The aluminous material is mixed with sufficient carbon to effect a substantial reduction of the alumina, and is then fused. The reduced impurities are separated and the residue is mixed with an oxidising agent such as bauxite and again fused in an electric furnace. (B) The crude aluminous material is fused with a proportion of carbon sufficient theoretically for the complete reduction of the non-aluminous oxides and with sufficient metallic iron to prevent the reduction of the alumina.

—A. B. S.

[Aluminium chloride;] Process of purification [of —]. V. M. Weaver, Harrisburg, Pa., Assignor to Weaver Co. U.S. Pat. 1,269,236, June 11, 1918. Date of appl., Aug. 9, 1915.

ALUMINIUM chloride is purified by passing it through a bath of molten aluminium and collecting the purified aluminium chloride vapour which is evolved. The process may be applied to other compounds, the molten bath used being composed of the metal forming the base of the compound to be purified.—J. H. P.

Sodium hydrosulphite; Method of manufacturing —. A. K. Gyzander, Westbrook, Me. U.S. Pat. 1,270,150, June 18, 1918. Date of appl., Apr. 14, 1917.

SALTS of sulphurous acid are converted into hydrosulphites by the action of hydrogen gas under pressure.—J. H. P.

Sodium aluminate; Process of making —. W. L. Melick, Columbus, Ohio. U.S. Pat. 1,271,192, July 2, 1918. Date of appl., May 7, 1917.

A SATURATED aqueous solution of sodium hydroxide is heated to boiling with bauxite ground to the fineness of at least 70-mesh. The mixture is in the form of a thick paste, the consistency of which is maintained during the boiling, by the addition of water. The sodium aluminate formed is subsequently separated.—J. H. P.

Calcium carbide; Process of making high percentage —. D. R. Russell, Chicago, Ill. U.S. Pat. 1,271,229, July 2, 1918. Date of appl., Mar. 25, 1918.

ELECTRODES are inserted in a conglomerate of lime and carbon which is then smelted to high percentage

calcium carbide. The carbon used is pitch coke made from the pitch of completely distilled by-product coke-oven coal tar.—J. H. P.

Cyanides and ammonia; Process of manufacture of —. L. P. Devaucelle, Courbevoise, France, and F. Bensa, Genoa, Italy. Eng. Pat. 12,946, Sep. 9, 1915. Under Int. Conv., Sep. 9, 1914.

VIII.—GLASS; CERAMICS.

Glass; Notes on annealing —. S. English and W. E. S. Turner. J. Soc. Glass Technol., 1918, 2, 90—102.

BADLY annealed or strained glass readily breaks or shatters when exposed to shock or sudden change of temperature. To anneal a glass properly, it must be heated to a temperature at which all strain rapidly disappears without the glass undergoing deformation, and the subsequent cooling must be as rapid as possible without any recurrence of

strain. Specimens of strained glass were heated until free from strain when examined between crossed nicols, the temperature and time of heating being noted. If the temperature is sufficiently high the disappearance of the strain is very rapid. The authors conclude that the time-temperature curve representing ideal conditions of annealing is a double one, indicating that a glass may be cooled rapidly to just below the temperature at which strain disappears, but between this critical point and that at which the glass becomes rigid the cooling must be very slow. When the glass is rigid it may again be cooled rapidly. Thus, a glass with an upper critical temperature of 585°—590° C. may be cooled at the rate of 25° per hr. from 590° to 500° C., but even when the rate of cooling is only 9° per hour between 509° and 400° C. a slight strain is produced. The temperature at which the more rapid cooling of the rigid glass may be commenced varies with different glasses; it may be found by cooling glasses rapidly from different temperatures and then examining them to see which are strained, or by watching the movement of the rings when the glass is cooled between crossed nicols. In the latter case, the highest temperature which will not cause the rings to move in 12 hrs. may be taken as the temperature below which the cooling may be accelerated. In manufacturing practice, a lehr with three distinct cooling stages is recommended. Electric lamp bulbs and wine glasses made of lead glass may be annealed by placing them in a hot box lined with asbestos and allowing them to cool freely. Alkali-lime glasses may be cooled from the annealing temperature (about 550° C.) to 320° C. in 3½ hours, and below that temperature in a further 3 hrs. Boric oxide heat-resisting lamp glasses are rather difficult to anneal, very careful cooling between 500° and 360° C. at a rate not exceeding 9° C. per hour being necessary; below 360° C. a more rapid cooling is satisfactory. Glasses used for chemical work are the most difficult to anneal; one examined by the authors cannot be cooled between 500° C. and 400° C. without showing some signs of stress, whilst others may be annealed rapidly.—A. B. S.

Cristobalite and tridymite; Melting points of — [and new high-temperature electric furnace]. J. B. Ferguson and H. E. Merwin. Amer. J. Sci., 1918, 46, 417—426.

CLEAR quartz crystals were heated for 144 hrs. at temperatures ranging from 1300° to 1400° C., when the greater part of the material was inverted to cristobalite with a few clear nuclei of tridymite. These were separated and the melting points determined. The cristobalite melted at $1710^{\circ} \pm 10^{\circ}$ C. The tridymite grains inverted into cristobalite at 1667° — 1677° C. without melting. Natural tridymites, from Nevada and Mexico respectively, melted sharply at $1670^{\circ} \pm 10^{\circ}$ C. These results confirm the earlier observations of Fenner (this J., 1913, 22), but are in opposition to those of Le Chatelier (this J., 1917, 964) and show that the region of stability of cristobalite is above that of tridymite. The electric furnace used was constructed on the cascade principle, the inner coil being made of an alloy of platinum with 20% of rhodium and the outer coil of pure platinum. The inner coil is wound on a helically grooved magnesia tube and the two coils are insulated from one another by well burned magnesia powder. With this furnace the charge can be maintained above 1700° C. for periods of several hours in an oxidising atmosphere. (See also J. Chem. Soc., Oct., 1918.)—A. B. S.

Temperature-viscosity relations in the ternary system lime-alumina-silica. Feild and Royster. See X.

PATENTS.

Refractory material and process of making same. J. O. Handy and R. M. Isham, Assignors to Allen S. Davidson Co., Pittsburgh, Pa. U.S. Pats. (A) 1,270,818 and (B) 1,270,819, July 2, 1918. Dates of appl., Jan. 22 and 30, 1917.

(A) A CARBONATED refractory material, such as magnesium carbonate, is mixed with a liquid containing a small amount of a soluble chloride, dried, and calcined at a temperature high enough to expel most of the chlorine and to produce a refractory material free from carbon dioxide and resistant to air, steam, and hot water. (B) Dolomite is calcined, extracted with cold water until the lime present in the residue is reduced to 3–10%, and then re-heated with a small amount of a binding material.

—A. B. S.

Lining for furnaces. O. J. T. G. R. Martin, Vancouver. U.S. Pat. 1,271,052, July 2, 1918. Date of appl., Sep. 21, 1917.

A MIXTURE composed of 15 parts of brick clay, 8 parts of infusorial earth, 4 parts of soapstone, and 6 parts of asbestos, rendered plastic by water containing $\frac{1}{4}$ oz. of salt per gallon.—F. C. Th.

Aluminous abrasives; Preparing —. L. E. Saunders and R. H. White, Niagara Falls, N.Y., Assignors to Norton Co., Worcester, Mass. U.S. Pat. 1,269,222, June 11, 1918. Date of appl., Aug. 18, 1917.

A SMALL amount of an oxygen compound of zinc is added to the charge of material used for making aluminous abrasives in order to prevent the reduction of the alumina by the carbon in the charge.

—A. B. S.

Producing crystalline alumina. U.S. Pat. 1,269,141. See VII.

Purifying aluminous materials. U.S. Pats. 1,269,223 and 1,269,224. See VII.

IX.—BUILDING MATERIALS.

PATENTS.

Fibrous materials [wood]; Process of treating [waterproofing] —. G. B. Ferguson, Assignor to W. E. Silverthorne, New York. U.S. Pat. 1,268,446, June 4, 1918. Date of appl., Apr. 9, 1913. Renewed Oct. 27, 1917.

THE fibrous material to be rendered waterproof is immersed in a molten waterproofing substance and the air removed by suction from the pores. The temperature is then raised so as partly to char the fibres, and pressure is applied to force the liquid into the interstices of the material. The material is then withdrawn and allowed to cool.—F. C. Th.

Fibrous [roofing] material and method of making the same [from scrap leather]. A. L. Clapp, Braintree, Mass., Assignor to R. W. Bird, Framingham, Mass. U.S. Pat. 1,269,905, June 18, 1918. Date of appl., July 29, 1915.

FELT for roofing is made by disintegrating scrap leather into a fine, fibrous, pulpy mass, adding a softening agent, and then forming the mass into soft, porous sheets.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Basic steel process; Influence of badly burnt lime in the —. M. Backheuer, Stahl u. Eisen, 1918, 38, 748–750.

LIME for slag making in the basic process should give a loss on ignition of not more than 2–4%, or at the highest 6%. Dead-burnt lime, however, is dissolved with difficulty in the slag. Badly burnt lime exercises a harmful influence both on the quality of the steel, resulting in non-metallic inclusions, and also on the working of the heats as a result of the chilling effect. In the basic Bessemer process poor lime results in an excessive loss of manganese, the steel being highly oxidised. The blow is abnormal and the elimination of phosphorus in the after-blow uncertain. With badly burnt lime 1.3% manganese is the minimum necessary in the mixer-iron used. Excessive loss during the blow and considerable production of scrap also result from the addition of incompletely burnt lime.

—F. C. Th.

Cyanide solutions; Estimation of oxygen in working —. H. A. White, J. Chem., Met., and Min. Soc., S. Afr., 1918, 48, 292–297.

A COLORIMETRIC method is based on the oxidation of alkaline photographic developers (e.g., pyrogallol, amidol) by dissolved oxygen, with the formation of quinones. A series of standard tints is made by saturating water at a known temperature with air, developing the colour by the addition of 0.1 gm. of pyrogallol and 1 c.c. of 2N sodium hydroxide, and suitably diluting. The sample of liquor is then treated similarly, care being taken to exclude air in all cases, and matched with one of the standard solutions. A more permanent series of tints can be produced by matching suitable solutions of dyes against the standards prepared from water of known oxygen content.—C. A. K.

[Copper.] *Experiments in fettling reverberatory furnaces.* F. Rutherford. Eng. and Min. J., 1918, 106, 109–110.

SINCE 1912, reverberatory copper-smelting furnaces have been provided with holes along the sides of the arch through which the charge is fed instead of being dropped in the centre of the bed. This method of fettling protects the side walls. The former practice of fettling with silicious ore and feeding of hot calcines at the centre has given place to feeding hot calcines at the sides of the furnace. In the former method a silicious scum or blanket is formed which covers the slag and causes loss of metal. If no calcines are available, the ore used for side-feeding should be as nearly self-fluxing as possible and contain enough sulphur to combine with the copper.—W. R. S.

Zinc oxide; Baghouses for —. J. F. Cregan. Eng. and Min. J., 1918, 106, 126–132.

Two types of baghouse, the Eastern and the Western, have gradually been evolved. The principal difference consists in the disposition of the bags: in the Eastern type, they are suspended from the distributing pipes situated just under the roof of the baghouse; the bags have a length of 44 ft. In the Western type the bags, which average 30 ft. in length, are fastened at their upper ends by means of ropes to pulleys suspended from the roof; the distributing pipes are laid along the floor of the baghouse. In the Eastern States the ores smelted are clean silicates free from lead and sulphur; the fuel is anthracite. In the West there is no constant ore or fuel supply. Silicates, carbonates, and

sulphides are smelted; practically all the ores contain lead, while the fuel used is coal high in sulphur and volatile matter. Western zinc oxide is sold according to chemical analysis as well as according to colour test.—W. R. S.

Zinc spraying process; An electrical — W. Kasperowicz. *Z. angew. Chem.*, 1918, 31, 144.

AN electrically heated apparatus for spraying molten zinc according to Schoop's "metallising" process has been introduced. The zinc is contained in the "pistol" in the form of two wires connected with any existing electric system and the points of these two zinc wires are caused to touch so that they short-circuit the current and form a small arc. The molten metal is immediately sprayed out by a jet of compressed air and the wires are fed forward by a mechanical arrangement, so that the points are always in the correct position to give a quietly burning arc for uninterrupted work. The best results are obtained with continuous current. The electrical process is more economical than the gas heating process, because the heat is generated only at the working points; moreover the apparatus melts and sprays twice as much metal in the same time as compared with the gas-heated "pistol." (See also this J., 1918, 472 A.)—J. F. B.

[*Lead.*] *Mechanical Scotch-hearth smelting.* W. E. Newnam. *Eng. and Min. J.*, 1918, 106, 101–104.

MECHANICALLY operated Scotch hearths are now in general use in the Middle Western States, as well as in Canada and Spain, at places where the supply of galena is insufficient for blast-furnace work. Some plants have a daily capacity of 100 tons of concentrate. Two types of installation are in vogue. In the first, the hearths are placed in a straight line facing in the same direction; the flue system is placed outside the building. In the second, the hearths are placed in two lines, facing in opposite directions, with the flue system between the lines. This arrangement is employed where the space is limited, or where a large number of hearths are installed. The quantity of grey slag formed averages 2% of the ore. Drawings are given for a 100-ton plant comprising five mechanically operated hearths.—W. R. S.

Coal; Use of pulverised — [in lead smelting]. C. T. Rice. *Eng. and Min. J.*, 1918, 106, 91–94.

THE furnaces of the refining plant at the Bunker Hill lead smelter (Kellogg, Idaho) are fired with pulverised coal, which is far cheaper than oil. The Holbeck return-circuit system is used, in which the coal is crushed in a closed circuit and under partial vacuum. The powdered coal is also circulated by a current of air in a closed circuit throughout the plant, the excess returning to the bins of the system after the desired amount of coal has been drawn off by means of deflectors to the burners. 85% of the coal dust is smaller than 220-mesh. The pulveriser crushes 20 tons (24 hours' supply) of slack in 8 hours, two men being required.—W. R. S.

Lead; Determination of — in ores, etc. W. Stahl. *Chem.-Zeit.*, 1918, 42, 317.

A WEIGHED quantity of the finely-divided sample is mixed with about 500 c.c. of water, acidified with nitric acid, and heated at 40° C. for 2 hrs. The mixture is then diluted with water, treated with hydrogen sulphide, filtered, and the insoluble portion washed with warm water containing a small quantity of potassium sulphide. The insoluble portion is then heated with nitric acid until all

sulphur has been oxidised, the solution evaporated with the addition of sulphuric acid, and the lead sulphate, etc., collected and washed with dilute sulphuric acid. The precipitate is then extracted with warm ammoniacal ammonium tartrate solution, filtered, and the insoluble portion washed with warm water. The filtrate now contains the lead sulphate together with antimony; the antimony remains in solution when the filtrate is acidified with sulphuric acid and mixed with alcohol, whilst the lead sulphate is re-precipitated; and is collected, dried, and weighed.—W. P. S.

Antimony; Pure — E. Groschuff. *Z. anorg. Chem.*, 1918, 103, 164–188.

TECHNICALLY refined antimony is purer than electrolytic antimony prepared by the electrolysis of antimony sulphide solution. The latter, by further refining, gives a highly pure product containing less than 0.02 impurity. To obtain chemically pure antimony, the tri- or pentachloride is distilled and converted into chloroantimonic acid, $\text{SbCl}_4\text{H}_4\text{O}$, which can be freed from all impurities by recrystallisation. The purified product is hydrolysed to antimonic acid, which is reduced by fusion with potassium cyanide. Antimony so prepared contains no recognisable impurities. Its melting point, which is an important fixed point in thermometry, is 630.3° C. A method has been devised for detecting and estimating the impurities in nominally pure antimony. The principle of the method consists in converting the antimony into chloroantimonic acid, which is then fractionally crystallised. The impurities are concentrated in the mother liquors, which are subsequently analysed by the usual methods. (See also *J. Chem. Soc.*, 1918, ii., 322.)—E. H. R.

Mercury; Extraction of — from its ores by sodium sulphide. C. H. Holland. *New Zealand J. Sci. Tech.*, 1918, 4, 153–154.

ONE part of an ore containing einnabar, ferrie oxide, and a hydrocarbon is crushed, and agitated with 4.5 parts of an aqueous solution containing 4% sodium sulphide and 1% sodium hydroxide. The solution is filtered and mercury is precipitated from the double sulphide of mercury and sodium by aluminium shavings. The mercury is obtained partly in metallic form, and partly as a powder mixed with foreign matter, which is heated in a retort with manganese dioxide and lime. The total yield of mercury is 84.5%.—W. F. F.

Lime-alumina-silica; Temperature-viscosity relations in the ternary system — A. I. Feild and P. H. Royster. U.S. Bureau of Mines. *Tech. Paper* 189. 1918. 33 pages.

THE investigation was confined to that range of composition encountered in iron-blast-furnace slags. Synthetic melts were made and their viscosities measured at temperatures ranging from the melting point to an upper limit of 1600° C., an electric furnace being used and the temperatures measured by a Holborn-Kurlbaum optical pyrometer. The viscosity was estimated by rotating the graphite crucible containing the molten material and determining the torque on a steel ribbon used to suspend a graphite rod in the axis of the crucible. In the binary system calcium metasilicate-gehlenite ($\text{Ca}_2\text{Al}_2\text{SiO}_7$), a maximum viscosity for temperatures between 1350° and 1600° C. is shown by a mixture of about 30% gehlenite and 70% calcium metasilicate, and a minimum viscosity by the eutectic mixture. At the saturation temperature and at 50° and 100° C. superheat respectively, the binary eutectic exhibits maximum viscosity when

compared with contiguous mixtures. Viscosity-temperature measurements were made of mixtures representing seven quintuple points of the ternary system. Two of these mixtures (CaO 47.2, Al_2O_3 11.8, SiO_2 41%, and CaO 49.5, Al_2O_3 43.7, SiO_2 6.8% respectively) do not obey the usual rule of possessing a viscosity-temperature curve continuous at the melting point, so that crystallisation of these mixtures should proceed without great difficulty. Viscosity measurements were made of compositions lying on the boundary curves between the fields of calcium metasilicate and anorthite, calcium metasilicate and gehlenite, gehlenite and anorthite, and calcium orthosilicate and gehlenite at temperatures of 1400° , 1500° , and 1600°C . Each of the viscosity-composition curves terminates at a quintuple point representing a eutectic and includes between these two ternary eutectics the binary eutectic between those two compounds whose stability fields it limits. In the boundary curve between calcium orthosilicate and gehlenite there are also two quintuple points which are not eutectics, *viz.*, the points where gehlenite, α - and β -calcium orthosilicate are in equilibrium with their melt. The viscosities of the mixtures corresponding to these two points are much higher than for any composition lying in this part of the system; this appears to be due to the existence of the molecular aggregate identified with β -calcium orthosilicate. In each of these boundary curves the viscosity increases from a minimum at a binary eutectic to a maximum at a quintuple point. Some idea of the general nature of the isothermal viscosity surfaces may be gained from the profiles of these surfaces at 1450°C . shown for mixtures containing 7, 10, 15, 18, and 21% Al_2O_3 respectively. In Fig. 1 for 7% Al_2O_3 the boundary curve between the fields of calcium metasilicate and akermannite occurs at a ; f lies on the boundary curve of the binary system calcium metasilicate-gehlenite, and b on that of the

FIG. 1.

Profiles of the isothermal viscosity surfaces at 1450°C . for mixtures containing 7 and 10% Al_2O_3 .

boundary system calcium metasilicate-anorthite. For the curve representing 10% Al_2O_3 the letters a' , f' , and b' show the intersection of the same curves, this part of the calcium metasilicate field having a low viscosity. The curve for 15% Al_2O_3 (Fig. 2) starts on the left of the binary system metasilicate-anorthite and passes to the gehlenite field, the viscosity decreasing to a minimum at 45% CaO and then increasing rapidly with increas-

ing lime. The curve for 18% Al_2O_3 (Fig. 2) starts at a composition corresponding to the eutectic between the metasilicate and anorthite and increases to a maximum at the point representing the intersection of the metasilicate-gehlenite binary system (44.5% CaO) and then decreases. At 37.5% CaO the curve for 21% Al_2O_3 (Fig. 2) begins with a high viscosity because of its proximity to a quintuple

FIG. 2.

Profiles of the isothermal viscosity surfaces at 1450°C . for mixtures containing 15, 18, and 21% Al_2O_3 .

point and then decreases with increasing lime. The viscosity surfaces are not of a simple nature at any given temperature and their form depends greatly on the temperature. In the present field it is obviously futile to search for a general relation between viscosity and percentage composition, as the melted mass is not a mixture of oxides but of more complex compounds. Hence, the desulphurising power of a slag cannot be expressed simply in terms of the percentage of lime present. The investigation of what occurs in manufacturing processes involving molten silicates is still further complicated by the fact that even an approach to equilibrium is seldom obtained.—A. B. S.

Vanadium in sedimentary rocks; A possible source of —, A. H. Phillips, Amer. J. Sci., 1918, 46, 473—475.

A brown, spotted holothurian, *Sticopus mobilis*, found at the Tortugas contains 0.123% V after being dried at 110°C . The author suggests that the occurrence of vanadium in sedimentary rocks and coals may be due to its withdrawal from solution in water by this or similar organisms.—A. B. S.

PATENTS.

Open-hearth steel process. C. H. Elliott and E. T. McCleary, Assignors to The Youngstown Sheet and Tube Co., Youngstown, Ohio, U.S. Pat. 1,265,928, May 21, 1918. Date of appl., July 20, 1917.

NEAR the end of the heat, the composition of the bath of metal is tested, silicon being added to the bath to retain the carbon during the testing period. The metal may be re carburised after addition of the silicon.—C. A. K.

Electrolytic deposition of metals. N. H. M. Dekker, Paris. Eng. Pat. 117,638, Apr. 21, 1917. (Appl. No. 5632 of 1917.)

A METALLIC salt is melted by means of a steam jet so as not to cause the loss of water of crystallisation as would happen if the salt were melted by external heat. Around the anode the aqueous solution of the acid formed by the electrolysis is neutralised by the addition of an oxide, hydroxide, or basic salt of the metal to be produced. The resulting salt is, when present in sufficient quantity, removed and added to the bath and the metal recovered.—F. C. Th.

Electrodeposition; Process and apparatus for —. N. Huggins, New York, Assignor to Copper Products Co. U.S. Pat. 1,268,465, June 4, 1918. Date of appl., Apr. 18, 1916.

A ROTARY cathode is formed with end journals which fit into slots in the walls of the electrolytic tank, so that the cathode may be easily removed. Conducting mould-blanks are mounted on and in contact with the cathode, with walls of insulating material adjacent to and between the mould-blanks. The insulating walls extend beyond the mould-blanks, thus forming cavities for the deposited metal. A source of electric current is connected to the cathode and to a suitable anode.—B. N.

Electrodeposition under compression; Process and apparatus for —. E. G. Cook, Long Island City, N.Y., Assignor to Copper Products Co. U.S. Pat. 1,271,136, July 2, 1918. Date of appl., May 13, 1916. Renewed May 11, 1918.

A CONDUCTING mould is mounted on a cylindrical conducting cathode and has a series of insulating rings outstanding so as to leave a series of annular cavities in which the metal is electrolytically deposited. During the deposition the deposit is mechanically burnished.—F. C. Th.

Separation of mineral values from ores by the flotation process. K. Sundberg, Stockholm. Eng. Pat. 117,781, Feb. 19, 1918. (Appl. No. 2964 of 1918.)

A MIXTURE of minerals is treated by the flotation process in an apparatus with several compartments, and the foams from the first and last compartments respectively are taken separately to two other flotation apparatus and placed in the first or last chamber as the case may be and treated afresh. Three pieces of apparatus, each with five chambers, are used. The foams from the intermediate chambers are passed through again.—F. C. Th.

[Copper] ores; Process for concentrating —. R. H. Dosenbach, Butte, Mont. U.S. Pat. 1,238,940, June 11, 1918. Date of appl., Mar. 7, 1918.

ORE containing copper partly as sulphide and partly in a form which is convertible into copper sulphate by the action of sulphuric acid, is treated with acid and metallic copper then precipitated from the solution. The precipitated copper and unaltered sulphide are separated from the gangue by flotation.—W. P. F.

Ores; Process of and apparatus for concentrating —. C. J. B. Armstrong, Cobalt, Ontario, Assignor to Metals Recovery Co., Augusta, Me. U.S. Pat. 1,269,150, June 11, 1918. Date of appl., Mar. 15, 1917.

THE froth generated in a flotation tank by treating a pulp containing powdered ore and water and a frothing agent, with a gas, is accumulated in substantial depth and extended area above the pulp

level, and extended in the direction of its travel. The discharge through which the froth escapes is constricted horizontally, so as to prolong the retention period of the froth in the tank.—T. H. B.

Ores; Process of concentrating —. J. M. Callow, Salt Lake City, Utah, Assignor to Metals Recovery Co., Augusta, Me. U.S. Pat. 1,269,157, June 11, 1918. Date of appl., Nov. 2, 1916.

THE ore is reduced, in presence of a frothing agent, to a fineness sufficient to liberate the metallic constituents, and sodium bisulphate is added to the fine ore in sufficient quantity to immunise certain mineral components against flotation. On subsequently subjecting the material to flotation treatment, with or without addition of an acid, a selective action on one metallic constituent is obtained.—T. H. B.

Metalliferous materials; Process and apparatus for utilising sulphurous gases with treatment of —. *Process and apparatus for sulphatising metalliferous ores.* G. C. Westby, Ludwig, Nev., Assignor to Western Process Co. U.S. Pats. (a) 1,266,731 and (b) 1,266,732, May 21, 1918. Date of appl., Apr. 10, 1917.

(A) METALLIFEROUS ores, not containing fine particles, are charged into a closed tower, and subjected to the action of waste sulphurous gases, the top of the ore column being, at the same time, sprayed with a non-alkaline liquor. The soluble values are leached from the ore and are recovered from the base of the tower. (B) The process is applied to metalliferous fines by arranging them in low heaps on spaced transverse supports in a tower, the heaps in adjacent rows not being in alinement. Steam may be injected with the sulphurous gases.

—C. A. K.

Nickel; Method of separating — *from nickel-copper alloys.* J. Dhavernas, Assignor to United States Nickel Co., New Brunswick, N.J. U.S. Pat. 1,266,775, May 21, 1918. Date of appl., July 13, 1916.

COPPER-NICKEL matte is roasted, the oxidised material reduced to metal, and treated with an acid so as to dissolve the nickel. Small quantities of dissolved copper are precipitated by the addition of metallic nickel, and the solution of nickel salts is drawn off and treated to obtain the metal.

—C. A. K.

Blast-furnace, and blast-furnace operation. E. E. Slick, Westmont borough, Pa. U.S. Pats. 1,267,004 and 1,267,005, May 21, 1918. Dates of appl., June 29, 1914, and Apr. 16, 1915.

UNDER a charging bell and hopper a stationary distributor, surrounding the bell when lowered, has a number of fingers arranged to deflect portions of the charge towards the centre of the furnace whilst allowing other portions to pass towards the furnace wall. There are thus formed an inner and an outer series of heaps with intermediate portions of coarser materials, and the charge smelts and settles uniformly.—C. A. K.

Smelting furnace. T. A. M. Stevenson, Winston-Salem, N.C. U.S. Pat. 1,269,974, June 18, 1918. Date of appl., Mar. 29, 1917.

A WAGON on rails acts as a crucible to hold the product of a smelting furnace, a second one acting as a forehearth. These are run into a compartment provided with outlets for the slag and metal runners and also with a shaft admitting cold air.

—F. C. Th.

Smelting and refining furnace. O. J. T. G. R. Martin, Vancouver. U.S. Pat. 1,271,051, July 2, 1918. Date of appl., July 28, 1917.

THE furnace has two superposed compartments heated by electric current from carbon electrodes built in the walls. The top compartment has a charging opening above and a discharge aperture at the lower end, whence material passes into the lower compartment. Means are provided for opening and closing the doors and for indicating the height of the charge in each compartment.

—F. C. Th.

Electrodes for electric welding; Treating — J. H. Gravell, Brooklyn, N.Y., Assignor to Thomson Spot Welder Co., Boston, Mass. U.S. Pat. 1,267,400, May 28, 1918. Date of appl., Oct. 20, 1917.

A THIN layer of fusible metal, of melting point lower than that of the electrode, is applied between the electrode and the surface of the work engaged by it, and pressure is applied.—B. N.

Copper alloy; Process for producing a hard — O. C. M. Knudsen, Brooklyn, N.Y. U.S. Pat. 1,267,669, May 28, 1918. Date of appl., Mar. 22, 1917.

A HARD alloy containing only a small amount of aluminum is produced by melting aluminum and adding copper broken into small particles. The temperature is then raised to melt the copper and the whole well mixed.—F. C. Th.

Tungsten ingots; Process for welding — C. A. Pfanstiehl, Waukegan, Ill., Assignor to Pfanstiehl Co., Inc., North Chicago, Ill. U.S. Pat. 1,267,801, May 28, 1918. Date of appl., Oct. 15, 1915.

AN ingot consisting of compressed tungsten particles is compressed longitudinally and at the same time heated to the sintering temperature by an electric current passed through the ingot from a pair of carbonised tungsten electrodes pressed against its ends.—F. C. Th.

Tungsten powder; Production of metallic — P. G. Keyes, East Orange, N.J., Assignor to Cooper Hewitt Electric Co., Hoboken, N.J. U.S. Pat. 1,270,812, July 2, 1918. Date of appl., July 6, 1914.

TUNGSTEN oxide is reduced by intimately mixing it with an alkali metal dissolved in liquid ammonia, the latter being distilled off and the residue heated slowly to 500°–600° C.—T. H. B.

Electrical reduction of ores; Method and apparatus for — B. G. Cobb, Dawson City, Canada, Assignor to J. F. Skerrett, H. Giffin, H. M. Kidder, R. I. Barr, and E. Inescort, New York, and Andes Exploration and Smelting Corporation, U.S. Pat. 1,267,976, May 28, 1918. Date of appl., May 23, 1913. Renewed Oct. 11, 1917.

AN ore is produced between electrodes in the charge of crushed ore. A supplementary current is passed between a pair of electrodes of an independent circuit placed on the surface of the ore mass at a definite distance from the positive electrode of the main circuit, and the polarity of the supplementary electrodes is frequently reversed.—F. C. Th.

Coating process [for metals]. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,268,030, May 28, 1918. Date of appl., July 3, 1914.

A FINELY divided metallic oxide is fed into a reducing flame which melts it and reduces the oxide

to metal, which is sprayed in the liquid state on to the surface by the flame.—F. C. Th.

Ores; Process of treating — H. E. Cleaves and F. W. Horton, Washington, D.C. U.S. Pat. 1,268,323, June 4, 1918. Date of appl., Mar. 14, 1917.

ORE containing one or more of the metals lead, zinc, and copper, is treated at a temperature of 800°–1100° C. with gaseous hydrogen chloride. The lead and zinc chlorides are volatile at that temperature and distil off to be subsequently condensed.

—F. C. Th.

Fume-arrester for smelting plants. A. Ferrari, Collinsville, Ill. U.S. Pat. 1,268,417, June 4, 1918. Date of appl., Sep. 1, 1917.

THE fumes pass from the furnace into a horizontal condensing passage and thence to a chimney. The interior of the passage and part of the stack are sprayed with water from perforated tubes.

—F. C. Th.

Metal composition [alloy]. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,268,495, June 4, 1918. Date of appl., Mar. 23, 1917.

A NICKEL-TUNGSTEN alloy consisting essentially of more than 50% Ni, preferably 4 parts Ni and 1 part W, and more than 3% of graphite carbon.

—F. C. Th.

Metals; Process for chemically extracting pure — from their ores. F. G. Clark and A. T. Stuart, Assignors to The Toronto Power Co., Ltd., Toronto, Canada. U.S. Pat. 1,269,054, June 11, 1918. Date of appl., July 5, 1917.

THE ore and a gaseous reagent in regulated quantities are passed through a reaction zone at a temperature sufficient to cause the reaction but below the fusing point of the metals. The gaseous reagent combines with oxygen, sulphur, phosphorus, and manganese, and the metals are separated in a pure state.—T. H. B.

Lead or zinc or both metals; Continuous process for recovering — from ores or slag. F. Ohlmer, Griesheim, Germany. U.S. Pat. 1,269,110, June 11, 1918. Date of appl., Sep. 26, 1914.

A WET mixture of the metalliferous material with carbonaceous fuel is fed into a revolving furnace in which it is heated at a temperature below the reduction temperature of zinc oxide, to granulate the charge, which is then fed into a second revolving furnace, and heated sufficiently in a reducing atmosphere to reduce the oxides, without smelting, the metallic fumes being afterwards oxidised in an oxidising zone.—T. H. B.

Metals; Method of recovering — from solution. R. Gahl, Miami, Ariz. U.S. Pat. 1,269,418, June 11, 1918. Date of appl., Aug. 15, 1917.

THE metals, e.g., copper or iron, are recovered from dilute solutions of, for instance, the sulphates by adding a large excess of a suspension of finely divided limestone. The limestone precipitate is divided into richer and poorer fractions, the poorer parts being added to a fresh quantity of solution.

—F. C. Th.

Rust prevention. C. I. Geseh, Mamaroneck, N.Y. U.S. Pat. 1,269,926, June 18, 1918. Date of appl., Jan. 7, 1918.

THE metal is provided with a coating of non-metallic paint, having holes or fissures in it, and is made the negative electrode of a voltaic cell, e.g., by holding it in contact with an unpainted body of zinc in sea water.—T. H. B.

Metallic articles; Box for treating — by heat. Means for heat-treating metallic articles. J. C. Henderson, Washington, D.C., Assignor to Driver-Harris Co., Harrison, N.J. U.S. Pats. (A) 1,270,519 and (B) 1,270,520, June 25, 1918. Dates of appl., July 8, 1916, and Feb. 1, 1918.

(A) A CLOSED container for use in the heat treatment of metals is made from a non-warping and heat-resisting alloy containing from 5 to 30% of Cr and from 50 to 90% of a metal of similar atomic weight to iron and classified with it in Mendeleff's table. (B) A carrier for articles to be heat treated at high temperatures consists of a cast perforated basket of an alloy of nickel and chromium of low heat conductivity.—C. A. K.

Case-hardening material. H. Rodman, Edgewood, Pa., Assignor to Rodman Chemical Co., Verona, Pa. U.S. Pat. 1,270,874, July 2, 1918. Date of appl., Aug. 29, 1914.

THE metal to be carburised is packed in a mixture of charred resins and lignose, e.g., the by-product of wood fibre manufacture known as black ash, and the whole heated.—T. H. B.

Graphite; Method of recovering — from slag. E. C. Ewen, Saginaw, Mich. U.S. Pat. 1,271,146, July 2, 1918. Date of appl., Dec. 17, 1917.

MOLTEN metal from a furnace is poured into a ladle, the metal is then removed from the ladle whilst holding back the slag and another charge of metal is poured upon the latter. The metal is then again removed, whilst holding back the slag, which is afterwards screened and finally subjected to the action of an air separator to recover the graphite.

—T. H. B.

Cadmium-evolving process. W. McA. Johnson, Hartford, Conn. U.S. Pat. 1,271,172, July 2, 1918. Date of appl., July 30, 1914.

A SULPHUR-BEARING ore of cadmium and zinc is incompletely roasted so as to reduce the sulphur to about 3%. The material is then reduced in a current of gas at a temperature sufficiently high to evolve cadmium vapour but too low to evolve zinc. The residue is treated at a higher temperature to produce zinc containing only a trace of cadmium.

—F. C. Th.

Tin; Method of and apparatus for smelting —. E. N. Morrill, Warren, N.H., Assignor to Andes Exploration and Smelting Corporation. U.S. Pat. 1,271,200, July 2, 1918. Date of appl., Nov. 27, 1917.

A CRUCIBLE furnace lined with magnesite and cooled by water-cooled plates is heated to a temperature slightly below the boiling point of tin by passing an electric current through a bath of molten slag. From time to time tin ore, slag, and reducing material are added, each charge being smaller in quantity than the molten material already present. The approximate proportions of the constituents of the charge are 60% tin concentrates, 1000 lb.; slag, 100 lb.; lime 35–50 lb.; silica, 50–70 lb.; and coal, 125–150 lb.—F. C. Th.

Blast-furnaces, kilns, or the like; Elevators for —. Soc. J. Munier et Cie., Frouard, France. Eng. Pat. 111,673, Nov. 23, 1917. (Appl. No. 17,299 of 1917.) Under Int. Conv., Nov. 28, 1916.

Blast-furnace skips. Soc. J. Munier et Cie., Frouard, France. Eng. Pat. 111,674, Nov. 24, 1917. (Appl. No. 17,370 of 1917.) Under Int. Conv., Nov. 25, 1916.

Electroplating articles or pieces having holes; Apparatus for use in —. Platt Bros. and Co., Ltd., Oldham, and G. L. A. R. B. Colin, Uccle, Belgium. Eng. Pat. 117,658, July 23, 1917. (Appl. No. 10,535 of 1917.)

Concentration of crushed ores; Apparatus for —. W. McDermott, London. Eng. Pat. 118,074, May 14, 1918. (Appl. No. 8076 of 1918.)

Zinc; Electrothermic extraction of —. E. S. Berglund, Trollhättan, Sweden. U.S. Pat. 1,271,267, July 2, 1918. Date of appl., July 25, 1917.

SEE Eng. Pat. 109,435 of 1917; this J., 1918, 185 A.

XI.—ELECTRO-CHEMISTRY.

Melting points of cristobalite and tridymite [and new high-temperature electric furnace]. Ferguson and Merwin. See VIII.

An electrical zinc spraying process. Kasperowicz. See X.

PATENTS.

Electrolysis of water; Apparatus for the —. K. Kimura, Kobe, Japan. Eng. Pat. 117,533, Sep. 19, 1917. (Appl. No. 13,441 of 1917.)

SEVERAL anodes and cathodes are suspended from a detachable tank cover, the latter being provided with a series of pole-chamber heads which are separately connected to and in independent communication with box-like screens surrounding the suspended anodes. The lower edges of the anode screens and the suspended pole plates are kept in position by distance pieces, and the interior of the tank is thus divided by the screens into a series of anode chambers and a single cathode chamber.

—B. N.

Electrolyte; Film-forming —. J. Coulson, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,266,557, May 21, 1918. Date of appl., May 3, 1916.

THE claim is for an electrolyte containing ammonium citrate the concentration of which is substantially expressed by the equation $P = 3310 \times 2.72^{0.0161v}$, where P equals the percentage concentration of the electrolyte and v equals the voltage which is to be used. The percentage concentration should not be materially over 2% and must be less than 10%.—B. N.

Electrode; Totally-submerged —. H. H. Stout, Assignor to Nichols Copper Co., New York. U.S. Pat. 1,267,141, May 21, 1918. Date of appl., July 25, 1916.

THE electrode is suspended by means of lateral lugs resting on ledges carried by the side walls of the electrolytic tank, and the side walls are provided with portions extending above the ledges, so that the top edge of the electrode is below the top of the tank. The electrode is thus totally submerged in the electrolyte.—B. N.

Anode connector. J. H. Gillis, Assignor to British America Nickel Corporation, Ltd., Toronto, Canada. U.S. Pat. 1,267,653, May 28, 1918. Date of appl., Oct. 15, 1917.

A SOLUBLE anode, used in conjunction with a suitable electrolyte, is provided with an anode connector of aluminium having one or more contact pieces of copper secured to it.—B. N.

Electric furnace; Device for closing the orifices in the roof and walls of an — through which the electrodes pass. T. H. Watson and Co. (of Sheffield), Ltd., and W. Travis, Sheffield. Eng. Pat. 118,023, Nov. 8, 1917. (Appl. No. 16,321 of 1917.)

Melting refractory substances by electric arcs; Methods for —. J. G. Webb, Richmond, Va., U.S.A. Eng. Pat. 115,017, Sep. 25, 1917. (Appl. No. 13,780 of 1917.) Under Int. Conv., Mar. 16, 1917.

XII.—FATS; OILS; WAXES.

Plant products from Colombia. A. L. Bacharach, Analyst, 1918, 43, 289—291.

Oil of *Jessenia polycarpa*.—This oil is obtained from the nuts of the "sejen" or "unamo" palm and is used medicinally and for cooking. It is a pale yellow slightly fluorescent oil, closely resembling olive oil in its behaviour in the elaidin test and in chemical and physical characters. Samples from three separate consignments gave the following results:— $[n]_D^{20} = 1.4682$; free fatty acids (as oleic acid) 1.9 to 2.6%; saponif. value 188.5 to 190.5; iodine value (Wijs) 73.5 to 74.8; one of the samples had sp. gr. (15°/4° C.) 0.9161; Hehner value 93.8; iodine value of fatty acids 79.5; molec. equiv. of insoluble fatty acids 273.

Seeds of *Caryodendron Orinocense*.—These seeds, known locally as "tacy," are roasted and used for food. They have a greyish-brown brittle husk (about 15.5% of the seed), and average about 3.1 grms. in weight. A sample of the kernels had the following composition:—water, 4.43; ash, 2.95; crude fibre, 2.40; oil, 53.3; proteins, 12.90; and non-nitrogenous substances, 24.00. Extracted "tacy" oil had the following characters:—sp. gr. (15°/4° C.) 0.9220; $[n]_D^{20} = 1.4744$; free fatty acids (as oleic acid), 15.8%; saponif. value, 188.1; Hehner value, 94.4; and iodine value (Wijs), 168.5.

PATENTS.

Fatty acids and their glycerides; Method for saturation by means of hydrogen of unsaturated — and apparatus therefor. Soc. de Stéarinerie et Savonnerie de Lyon, and P. Berthon, Lyons. Eng. Pat. 107,969, June 25, 1917. (Appl. No. 9120 of 1917.) Under Int. Conv., June 27, 1916.

HYDROGENATION of oils or fatty acids at a constant speed of reaction is effected by the progressive raising of the temperature and a methodical introduction of the catalyst, hydrolysis of the oil under treatment being avoided by removal of the water of reaction formed. In hydrogenating oils for edible purposes the apparatus described ensures the automatic distillation of the free fatty acids, thus avoiding contamination of oil by traces of metallic catalyst or the necessity for a subsequent neutralisation. The apparatus consists of a compressor for hydrogen, two reaction chambers in series or parallel, a tubular heat-exchanger where the temperature of the gas is automatically regulated and the greater part of the free fatty acid distilled over is condensed, two water-cooled tubular condensers for further condensation of the same, a chamber containing caustic soda where certain volatile impurities of the oils are absorbed, a water separator, a heat-exchanger for preliminary cooling, and a refrigerator for freeing the gas from the last traces of moisture prior to re-entering the cycle where fresh gas is added previous to entering the compressor. Means are provided at the base of the digester for ensuring perfect contact of the reagents and progressive and methodical distribution of the catalyst. The catalytic mixture is prepared in a steam-heated vessel fitted with an energetic agitating device formed by baffles and counter-baffles.—A. de W.

Oil; Apparatus for extracting —. W. J. Garnett, Eastport, Me. U.S. Pat. 1,271,028, July 2, 1918. Date of appl., Oct. 3, 1917.

A "COOKER VAT" and a reservoir are so arranged that the upper end of the latter is below the plane of the bottom of the former. A steam supply pipe extends into the "cooker vat," which is fitted on the bottom with a drain pipe leading to the reservoir. At the point where the drain pipe enters the reservoir it is fitted with an elbow, a bushing carried by the lower end of the elbow, and a reduced valved discharge pipe carried by the bushing.

—A. de W.

Fats; Method of super-refining —. S. R. Barnett, Belleville, Wis. U.S. Pat. 1,271,118, July 2, 1918. Date of appl., June 4, 1917.

IN order to remove free fatty acids, oils and fats are agitated with hot lime water in the presence of a catalyst (sodium bicarbonate). Carbon dioxide is then passed into the mixture to precipitate excess of lime and to prevent oxidation. The sludge, containing the calcium soaps, is separated.

—L. A. C.

Soap containing sulphur; Manufacture of —. T. Tanaka, Tokyo, Japan. Eng. Pat. 117,060, Apr. 30, 1918. (Appl. No. 7249 of 1918.) Under Int. Conv., Aug. 1, 1917.

NEUTRAL soap stock is mixed with melted rosin soap which has been incorporated with sulphur, and a mixture of sodium perborate, or similar oxygen-yielding salt, with a small amount of vaseline is added, and the whole kneaded into a homogeneous mass, and moulded into tablets. This soap does not emit hydrogen sulphide when used.—C. A. M.

Treatment of edible oils and fats and production of butter substitutes. Eng. Pat. 117,014. See XIXA.

Viscosity measuring instrument. U.S. Pat. 1,270,800. See XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine; Determination of — and the detection of adulterants. J. Tausz. Chem.-Zeit., 1918, 42, 349—351.

TURPENTINE and other unsaturated hydrocarbons combine with mercuric acetate, or are oxidised by it; one mol. of acetic acid is set free for each mol. of terpene, etc., present and a determination of this acidity gives a measure of the turpentine present. Ten c.c. of pure turpentine and 10 c.c. of the sample under examination are each diluted with methyl alcohol to 100 c.c. (the reaction proceeds more quickly in the presence of methyl alcohol) and 10 c.c. of each of these solutions is mixed with 50 c.c. of saturated mercuric chloride solution (in methyl alcohol) and 50 c.c. of N/10 potassium hydroxide solution (also prepared with methyl alcohol). The mixtures are diluted with 100 c.c. of water, shaken, kept in the dark for 1 hr., phenolphthalein is added, and sodium chloride solution is run in until a red coloration develops; the mixtures are then titrated with N/10 sulphuric acid. A control test, without turpentine, is made at the same time. Usually, turpentine substitutes do not react with mercuric acetate; rosin spirit yields a small quantity of free acetic acid, and if this adulterant is present, turpentine containing approximately the same quantity as the sample should be used for the comparison titration. When pure turpentine is heated under a reflux condenser for 3 hrs. with mercuric acetate solution and methyl alcohol, and then steam-distilled, no trace of oil is found in the distillate. Hydrocarbons, however, such as mesitylene, cumene, cymene, petroleum spirit, etc., pass almost quantitatively into the distillate and their quantity may be measured. The loss is about 0.2 c.c. for each 10 c.c. of hydrocarbon, but it varies with each apparatus and should be determined separately. This method permits further examination of the distilled adulterant. The reaction between turpentine and mercuric acetate may also be used gravimetrically. Five c.c. of the sample is diluted to 100 c.c. with methyl alcohol and 5 c.c. of this solution is mixed with 50 c.c. of saturated aqueous mercuric acetate solution and heated for 4 hrs. in a closed flask in a boiling water bath; after cooling, the mercurous acetate formed is collected, washed with alcohol and ether, dried, dissolved in nitric acid (1:1), the solution treated with sodium chloride, and the mercurous chloride collected and weighed. A control test is made at the same time, using pure turpentine; the quantity of turpentine in the sample is proportional to the amount of mercurous chloride found.—W. P. S.

Baghouses for zinc oxide. Cregan. See X.

PATENTS.

Ink for printing on paper; Process for the manufacture of —. J. Hope, Rouen. Eng. Pat. 117,023, Dec. 7, 1917. (Appl. No. 18,156 of 1917.)

SULPHUR colours produced by the action of sulphur or sulphides on organic substances (e.g. *Cochon de Laval*), are rendered soluble by means of sodium sulphide or converted into precipitates or lakes, and incorporated with oils, resins, varnishes, or other thickening agents to form printing inks.

Paper to which such inks have been applied may be completely bleached with chloride of lime and made into new paper.—C. A. M.

Writing inks [; Indelible —]. M. Shinozaki, Tokyo, Japan. Eng. Pat. 117,117, July 3, 1917. (Appl. No. 9534 of 1917.)

SOLUBLE Induline or other alkali-soluble dyestuff (90 grms.) is dissolved in caustic alkali solution (5 grms. in 2 galls.), and the solution incorporated with a mixture of lampblack or other finely-divided carbon (135 grms.) and caustic alkali solution (1 grm. in 0.4 gall.), with or without the addition of soft soap (15 grms.), and the whole heated and stirred until perfectly mixed.—C. A. M.

Paint [; Emulsion —]. R. Illemaun and J. A. Montgomerie, Glasgow. Eng. Pat. 117,785, Mar. 6, 1918. (Appl. No. 3900 of 1918.)

A PAINT miscible with water and yielding a water-proof coating is obtained by adding to a mixture of one part of pitch (or bitumen) and one part of tar, rendered fluid by the aid of heat, a liquid suspension of one part of clay and one part of water and heating the mixture, with agitation, for only a sufficient length of time to ensure incorporation without driving off the water. Agitation is then continued until cold. Other colouring matters may be added during the course of manufacture to obtain different coloured paints or the proportions given may be varied.—A. de W.

Coumarone resin and process of making same. C. Ellis, N. L. Foster, and Ellis-Foster Co., Montclair, N.J., U.S.A. Eng. Pat. 117,016, Nov. 13, 1917. (Appl. No. 16,653 of 1917.)

LIQUID aromatic hydrocarbons containing compounds such as coumarone and indene (e.g., coal tar naphtha distilling between 160° and 180° C.) are treated with a polymerising agent, such as aluminium chloride, or, preferably, sulphuric acid, in sufficient quantity to polymerise such compounds. The unchanged liquid is removed, and the soft resinous mass freed from the more volatile constituents by distillation, leaving a hard resin with an iodine value not much below 47. The distillation is preferably effected slowly up to 180° C. under a reduced pressure of about 29 in. of mercury.—C. A. M.

Phenols and formaldehyde; Manufacture of condensation products from —. T. I. K. M. Hiltermann, Amsterdam. Eng. Pat. 117,857, Aug. 16, 1917. (Appl. No. 11,789 of 1917.)

SOLID and transparent phenol-formaldehyde condensation products are obtained from crude material (cresol) without subsequent purification by employing the neutral salts of aromatic hydroxycarboxylic acids as condensing agents. An example of the process given is: 100 parts by weight of phenol, 80 parts by weight of 40% formaldehyde, and 5 to 10 parts of an approximately 50% aqueous solution of neutral sodium or potassium salicylate are heated together until reaction commences, the heat being then reduced. At the termination of the reaction the water contained in the raw materials is driven off, the mass cast into moulds, and hardened in open moulds at 60°—80° C.—A. de W.

Phenolic condensation products; Process of hardening —. J. P. A. McCoy, Wilkesburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,269,627, June 18, 1918. Date of appl. July 3, 1914.

A SUBSTANCE capable of decomposing with evolution of formaldehyde, e.g., paraformaldehyde, together

with a tannin condensing agent having no deleterious effect upon the dielectric strength or stability of the resulting product, e.g., catechol-tannin, is added to a fusible phenolic condensation product.

—A. de W.

Phenol-aldehyde condensation product. A. W. C. van Voorhout, Delft, Netherlands. U.S. Pats. 1,271,392 and 1,271,393, July 2, 1918. Dates of appl., Dec. 22, 1916, and Jan. 23, 1918.

See Eng. Pat. 110,041 of 1916; this J., 1917, 1185.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome [tanning] liquors; Action of neutral salts on —. A. W. Thomas and M. E. Baldwin. J. Amer. Leather Chem. Assoc., 1918, 13, 248—255.

MEASUREMENTS of hydron concentration were made by means of the hydrogen electrode on chrome liquors to which varying amounts of neutral salts had been added. Sodium and ammonium chlorides, especially the former, caused distinct increases in the hydron concentration, whereas the sulphates of the same metals had a less marked effect in the opposite direction except when the concentration of sodium sulphate was greater than half-molar. Magnesium sulphate in increasing concentration caused first a slight decrease and then a slight increase to nearly the original hydron concentration. The effect of sodium chloride was also studied with regard to time. A rapid increase in hydron concentration takes place immediately on adding the salt, after which there is a slow decrease to a value in excess of that of the original liquor.—F. C. T.

Leather analysis; Preparation of samples for —. F. P. Veitch and R. W. Frey. J. Amer. Leather Chem. Assoc., 1918, 13, 232—239.

SAMPLES of leather for analysis were prepared by planing heavy sole leather and also by shredding with a machine constructed of four circular saws with "staggered" teeth mounted together on a shaft. Analysis showed that not only did the shredded samples contain much less moisture than the planed samples, but also less soluble solids, the difference in the latter varying from 0.8 to 4.5%. This effect was attributed to heating, and a new machine was constructed of four $10 \times \frac{1}{16}$ " saws of the splitting-saw type, with large teeth, about one to the inch. The saws had a slight set and were driven at 1500 revolutions per minute. The cutting action was much improved, only a barely perceptible heating occurred, and the content of soluble matter proved on analysis to be always slightly greater than that of a planed sample.—F. C. T.

Leather; Determination of fat in —. L. E. Levi and A. C. Orthmann. J. Amer. Leather Chem. Assoc., 1918, 13, 313—318.

THE new fat solvent proposed by Wilson and Kern (this J., 1918, 313A), consisting of equal parts of ether and carbon tetrachloride, is more readily inflammable than Wilson and Kern allow. Moreover, it continues to extract soluble matter from leather for a very long time; for instance 50 grms. of leather after extraction for 19 hours with petroleum ether was extracted twice with the new solvent for four hours, and a third time for 15 hours, when the evaporation residue from the last extract amounted to 0.61% of the leather, two-thirds of the residue being soluble in water and the remainder soluble in alcohol. The authors claim

that concordant results with the new solvent are impossible unless the time of extraction is precisely specified for every kind of leather, and also that the solvent extracts much that is neither fat nor oxidised fat. Dry quebracho extract after careful treatment with petroleum ether showed 1.88% of soluble matter on extraction with the new solvent and the residue was very like that obtained similarly from leather. The new solvent always extracts considerable quantities of dyestuff and chrome soap from chrome leathers. One such residue showed 1.57% of ash, mostly chrome oxide. It is maintained that Wilson and Kern's criticism of the authors' method is based on too little experimental evidence.—F. C. T.

PATENTS.

Glue and like substances; Manufacture of products adapted to precipitate —. H. Wade, London. From Deutsch-Koloniale Gerb- und Farbstoff-Ges., Karlsruhe, Germany. Eng. Pat. 116,936, June 29, 1917. (Appl. No. 9420 of 1917.) Addition to Eng. Pat. 8818 of 1914 (see Fr. Pat. 471,924; this J., 1915, 438).

WHITE or slightly coloured products capable of precipitating glue are obtained by condensing formaldehyde with an α - or β -naphtholmonosulphonic acid, using about 1 mol. of the former to 2 mols. of the latter. The reaction is carried out in strongly acid solution containing at least 25% of water, preferably at the ordinary temperature.

—F. C. T.

Hides and the like; Apparatus for the treatment of —. B. H. Tilson and T. Melbourne, Warrington. Eng. Pat. 117,581. (Appl. Nos. 2054, Feb. 5, and 4015, Mar. 7, 1918.)

Two forms of apparatus are described for agitating the liquors with which hides are treated in the pits in the processes of leather manufacture. In one form, a pit with a concave bottom is used, provided at the sides with two swinging arms which are joined at the lower ends by cross-pieces in the form of paddles or blades. The swinging arms are rocked by an oscillating shaft, and hides are hung in the pits between the swinging arms and above the paddles or blades. In the other form of apparatus, the stirrer-device at the bottom of the pit extends over the entire breadth and about half the length of the pit, and the blades of the stirrer are provided with hinged one-way valves, and are rocked by means of an eccentric rod.—F. C. T.

Fibrous [roofing] material and method of making the same [from scrap leather]. U.S. Pat. 1,269,905. See IX.

XVI.—SOILS; FERTILISERS.

Potash in soils; Influence of gypsum upon the solubility of —. P. R. McMiller. J. Agric. Res., 1918, 14, 61—66.

SURFACE samples of five loam soils of different character were intimately mixed with 1% of gypsum, and sufficient water was added to make the moisture content equal to the moisture equivalent of the soil. The samples, together with controls, were kept in jars for three months. They were then shaken with water, and the amount of potash in the filtered solutions was determined by the platonic chloride method. Marked increases were found in the amounts of soluble potash in the treated over the untreated samples.—J. H. J.

Nitrate and nitrite assimilation [by plants]. XIII. Iron and oxygen as necessary agents for the reduction of alkali nitrites by auto-oxidisable compounds [sugars, etc.]. O. Baudisch. Ber., 1918, 51, 793—805.

THE author (this J., 1917, 730) has already reported that when solutions of dextrose are boiled with ferrous sulphate and sodium carbonate, deep-coloured solutions are obtained, containing iron in the form of an internal complex ("masked" iron), which have the power of reducing alkali nitrites to nitric oxide and ammonia, or nitrobenzene to aniline. It is now shown that this property is shared by aldoses and ketoses in general, such as dihydroxyacetone, glycollic aldehyde, levulose, and maltose, but is not exhibited by closely related alcohols, such as glycerol or mannitol. In addition, the power of reducing nitrites in the presence of "masked" iron is possessed by catechol, quinol, pyrogallol, gallic acid, quercetin, chrysarobin, etc. All these compounds are auto-oxidisable, that is they take up oxygen and yield hydrogen peroxide in the presence of water, and it is remarkable that, with the exception of the sugars, these compounds can only reduce in the presence of oxygen. In the case of the sugars, the necessary oxygen is supplied by the sugar molecule itself. Furthermore, traces of iron in the masked form must be present; manganese or copper will not do. Some of the above polyhydric compounds can make the complex themselves out of iron hydroxides, but not all of them. Phloroglucinol, for example, cannot produce a complex from ferric hydroxide, but it can from potassium ferricyanide. It is not necessary that the complex shall involve the auto-oxidisable substance itself; the iron may be applied as a complex with catechol-o-carboxylic acid, for example. The fact remains, therefore, that these auto-oxidisable substances, which are so widely dispersed in nature, can in the presence of oxygen bring about oxidations on the one hand (e.g., methyl alcohol to formaldehyde) and the reduction of nitrites, in the presence of oxygen and iron complexes, on the other, and the significance of this in bio-chemical questions is obvious. (See further J. Chem. Soc., Oct., 1918.)—J. C. W.

Aluminium ion; Distribution of the — in plants. J. Stoklasa. Biochem. Zeits., 1918, 88, 292—322.

TABLES are given showing the amount of aluminium in a large number of plants. The author calls attention to the fact that the xerophytes contain only small amounts, whereas the hydrophytes and hygrophilic plants contain relatively large amounts. (See also J. Chem. Soc., Oct., 1918.)—S. B. S.

Plants; Immunity of — towards the immediate principles which they elaborate. R. Combes. Comptes rend., 1918, 167, 275—278.

IT was found that plants of *Agrostemma githago* would grow satisfactorily under aseptic conditions in Knop's culture solution containing up to 1% of the glucoside, agrostemmasaponin, which the plant elaborates, whereas plants such as peas, radishes, and buckwheat showed marked signs of injury when the culture solution contained only 0.01% of the glucoside. The injury was shown by the disappearance of the root hairs, arrested development of the roots, and diminution in the dry weight of the root.—W. G.

PATENTS.

Nitrate of ammonia; Treatment of —. F. W. Howorth, London. From Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania. Eng. Pat. 117,823, Apr. 10, 1917. (Appl. No. 5063 of 1917.)

SEE U.S. Pat. 1,263,363 of 1918; this J., 1918, 385 A. The substance added is bog iron ore or kieselguhr, and the mixture may be subjected to a preliminary drying operation at a low temperature (20°—40° C.) before the final drying.

Phosphatic material; Process of concentrating —. H. A. Webster, Columbia, Tenn. U.S. Pat. 1,266,730, May 21, 1918. Date of appl., June 4, 1917.

LOW-GRADE phosphatic limestone is calcined until a substantial portion of the carbon dioxide is expelled, and the burnt rock is finely ground and suspended in a moving fluid. The lighter phosphorus-free particles are carried away by the stream whilst the heavier phosphatic material settles out.—C. A. K.

Process of producing gas and phosphatic fertiliser material. U.S. Pat. 1,269,795. See IIa.

XVII.—SUGARS; STARCHES; GUMS.

Unfermentable sugars (glucose) of cane molasses, their preparation, properties, and determination. C. Muller. Archief Suikerind. Neder-Indië, 1918, 26, 346—358. Int. Sugar J., 1918, 20, 377—378.

IN order to examine the question of the formation of glucose during the course of manufacture in the cane sugar factory, lime was heated with a 10% solution of pure levulose, with a 20% solution of invert sugar, and with a thick-juice (62° Brix), respectively, imitating in each case the conditions prevailing in practice as closely as possible. The concentration of the sugar, the time of heating, and the quantity of lime used, greatly influenced the yield of "glucose," but the temperature had little effect. An examination of the product obtained from cane thick-juice indicated that it is not simply an isomer of the formula, $C_6H_{12}O_6$, as the product obtained from levulose appears to be, nor a single compound to which a formula may be assigned, but rather a mixture of a series of compounds of high molecular weight (containing 12, 18, or more, carbon atoms), each possessing very different properties. For its determination, 50 grms. of cane molasses diluted to 500 c.c. with water was acidified with sulphuric acid, fermented with 25 grms. of pressed bottom yeast, and the volume completed to 550 c.c. After clarifying with normal lead acetate, and eliminating the excess of lead with sodium carbonate, the cupric-reducing power was ascertained by heating for 30 minutes only to 65° C., as recommended by Pellet (this J., 1917, 467). Operating in this way, the amount of "glucose" or unfermentable sugars was found to lie between 3.2 and 4.9% for cane molasses and 0.1 and 0.2% only for the beet product, the quantity in the former case for the same factory being found to vary somewhat according to the ripeness of the cane.—J. P. O.

Dextrose; Estimation of — by means of hypoiodite. R. Willstätter and G. Schudel. Ber., 1918, 51, 780—781.

THE dextrose solution is mixed with about twice the amount of N/10 iodine solution necessary for oxidation to gluconic acid, $C_6H_{12}O_6 + I_2 + 3NaOH = 2NaI + 2H_2O + HO(CH_2(CH(OH))_4CO_2Na$, a quantity

of $N/10$ sodium hydroxide which is 1.5 times as much as the iodine is slowly added, the mixture is left for 12–15 minutes (or 20, if the proportion of sugar is very small) and then the excess of iodine is titrated after acidifying slightly with sulphuric acid. Taking 10 c.c. of sugar solution, the average error is less than 0.1% with 1% solutions or less than 1.5% with 0.1% solutions. Under these conditions ketoses and sucrose are not affected, and, therefore, the method may be applied to the estimation of aldoses in mixtures.—J. C. W.

Lactose in admixture with sucrose and invert sugar; Determination of — J. Grosfeld. Z. Unters. Nahr. Genussm., 1918, 35, 249–256.

From the results of experiments with pure lactose and sucrose, empirical formulae have been deduced for calculating the percentage of lactose in a mixture containing also sucrose and invert sugar, the data required being the polarisation and reducing power of the mixture after inversion. The inversion is always made under the same conditions, namely, 50 c.c. of the solution mixed with 2 c.c. of hydrochloric acid (sp. gr. 1.125) and heated in a boiling water-bath for 30 mins. The reducing power is expressed in terms of invert sugar and the lactose is then calculated from the empirical formula:—

$$L = 1.20Z \frac{D_x - D_1}{D_1 - D_2}$$
 where Z is the quantity of "apparent invert sugar" calculated from the reducing power, D_x = the specific rotation found for the "apparent invert sugar," D and D_1 = the specific rotations of the inverted products from lactose (+70.6°) and sucrose (−16.7°), respectively, under the above conditions; $[D_1 - D_2]$ is thus 87.3°, and the formula becomes: $L = 0.01375Z(D_x + 16.7)$. The quantity of sucrose present is found from the formula: $S = 0.01145Z(70.6 - D_x)$, since 100% of sucrose gives 100% of "apparent invert sugar" under the conditions given. Tables are given which show the rotation and reducing power of the inverted products from various mixtures of lactose with sucrose, etc. Experiments with prepared mixtures of lactose and sucrose by this method gave satisfactory results. To determine lactose in sweetened condensed milk, 20 grms. of the sample is dissolved in water, treated with lead acetate, diluted to 100 c.c., and filtered; 50 c.c. of the filtrate is neutralised with hydrochloric acid, using methyl orange as indicator, 2 c.c. of hydrochloric acid (sp. gr. 1.125) is added in excess, the mixture heated in a boiling water-bath for 30 mins., cooled, treated with a few drops of phosphotungstic acid solution, diluted to 100 c.c., and filtered. After standing for 24 hrs., the filtrate is polarised and its reducing power determined and the results obtained calculated into lactose as described. The percentage of lactose found is multiplied by 0.94 to correct for the volume of the lead acetate precipitate.—W. P. S.

Cane-sugar; Process of manufacturing — N. M. Thomas, Pymble, N.S.W., and C. G. Petree, Bundaberg, Queensland. U.S. Pat. 1,266,882, May 21, 1918. Date of appl., Jan. 14, 1918.

In a process of crushing cane in stages, with intermediate maceration of the bagasse, the rich juice

from the earlier stages of crushing is defecated and the mud produced is mixed with thin raw juice from later crushings; this mixture is defecated and the mud therefrom is distributed over the bagasse at a stage of crushing when the liquid expressed from the bagasse is richer in sugar than the mud itself.—J. H. L.

Sugar-refining apparatus [centrifuge]. K. K. Kaita, Lahaina Main, Hawaii. U.S. Pat. 1,267,419, May 28, 1918. Date of appl., Oct. 18, 1917.

A CYLINDRICAL centrifugal basket, open at one end, and surrounded by a casing of similar shape, is mounted with its axis horizontal. Mounted on the same axis is a non-rotating sleeve movable into and out of the basket. This sleeve, equal in length to the basket, bears at one end a disc which just fits into the latter, and at the other end a larger disc which abuts against the open end of the casing when the sleeve is at the end of its travel in the basket. It bears also hoppers for charging massenite into the basket, an adjustable scraper for securing a uniform layer of sugar in the latter, and an adjustable comb for breaking up the sugar layer. The sleeve remains inside the basket throughout the centrifuging process, and is withdrawn to discharge the sugar.—J. H. L.

[Sugar refining:] Process of treating phosphoric acid to be used as a clarifier [in —]. T. Hayashi and U. Emura, Assignors to Kwanto Sanso Kabushiki Kaisha, Ltd., Tokyo, Japan. U.S. Pat. 1,263,080, June 11, 1918. Date of appl., May 24, 1917.

See Eng. Pat. 108,303 of 1917; this J., 1918, 317 A.

XVIII.—FERMENTATION INDUSTRIES.

Alcoholic fermentation; General relationship of aldehydes to — and the co-ferment of yeast. C. Neuberg. Biochem. Zeits., 1918, 88, 145–204.

A GENERAL confirmation of a previous statement of the author, that aldehydes accelerate the alcoholic fermentation of dextrose and mannose. The fact has been demonstrated by experiments with a large number of different aldehydes. With the exception of vanillin, all acted as accelerators. The author also confirms his former statement that a mixture of keto-acids with potassium phosphates acts as a co-ferment. (See also J. Chem. Soc., Oct., 1918) —S. B. S.

Beer [wort]; Utilisation of residues from [Brunswick] — O. Reinke. Chem.-Zeit., 1918, 42, 367.

IN the manufacture of strong Brunswick beer, the wort is evaporated until it contains 60% of extract, and then filtered. The residue thus separated still contains about 54% of soluble matter which may be extracted and used over again, whilst the insoluble portion, when dried and roasted, forms a coffee-substitute.—W. P. S.

Enzymes; Action of — VII. M. Jacoby. Biochem. Zeits., 1918, 88, 35–42.

FOR the development of the catalase of the bacterium *Proteus*, alanine and aspartic acid can be employed as well as leucine. In this respect, the catalase differs from urease, for the development of which leucine is essential. The catalase develops satisfactorily in a medium containing the above-mentioned amino-acids and sodium lactate with the necessary inorganic salts. (See also J. Chem. Soc., Oct., 1918.)—S. B. S.

PATENTS.

Alcohol; Process for producing — from burnt or roasted starch-bearing materials, etc. B. Kazmann, Battle Creek, Mich., Assignor to Kellogg Laboratories. U.S. Pat. 1,267,081, May 21, 1918. Date of appl., Mar. 31, 1917. Renewed Mar. 7, 1918.

The roasted or "burnt" material, after being subjected, if desirable, to re-heating or dry distillation and then cooled by means of air, is treated with saccharifying agents, the saccharine liquid obtained is fermented and the alcohol recovered. For example, the material may be extracted with hot water, the undissolved matter subjected to diastatic action, the saccharine liquid separated from the solid residue, the former sterilised by heat, any dextrins present in it saccharified by means of acid, and the product fermented and distilled.—J. H. L.

Distilling apparatus [for separating alcohol from beer]. A. L. Straus, Assignor to Baltimore Process Co., Baltimore, Md. U.S. Pat. 1,267,709, May 28, 1918. Date of appl., Aug. 31, 1917.

A DETACHABLE CONDENSER consisting of a water-cooled bundle of vertical open-ended tubes is fixed above the mouth of a vessel such as a wort-copper. The vapours condensed in the tubes flow back into the mouth of the copper but are there caught in a collecting pan situated inside the copper just below its mouth. This pan has a jacket for cooling water and it discharges through a tube, also water-jacketed, which passes through the wall of the copper and delivers the condensed alcoholic liquid into apparatus in which further separation of alcohol from water is carried out.—J. H. L.

Yeast; Process for pressing —. E. A. Meyer, Bristol. U.S. Pat. 1,268,865, June 11, 1918. Date of appl., Nov. 12, 1917.

SEE Eng. Pat. 113,628; this J., 1918, 255 A.

XIXA.—FOODS.

Cane sugar [sucrose] in milk; Detection of —. G. D. Elsdon, Analyst, 1918, 43, 292—293.

THE following modification of Gayaux's resorcinol test is capable of detecting 0.02% of sucrose in milk: Five drops of a mixture of 15 c.c. of the milk with 1 c.c. of hydrochloric acid and 0.1 gm. of resorcinol is evaporated to dryness on the water-bath in a depression of a white spotting tile. In the presence of sucrose a red coloration is produced.—C. A. M.

Butter fat; The glycerides of —. C. Amberger. Z. Unters. Nahr. Genussm., 1918, 35, 313—381.

A SAMPLE of butter fat examined by the author contained only 2.4% of triolein. By fractional crystallisation of the glycerides of hydrogenated butter fat from various solvents (alcohol, ether, acetone), it was found that the olein had not been converted into tristearin, but into a mixed glyceride. The greater part of the oleic acid in butter fat is therefore present as a mixed glyceride and not as triolein. The butyric and caproic acids are also present as mixed glycerides; tributyrin and tricaproin could not be isolated from the fat. Butyrodiolein, butyroylpalmito-olein, and oleodipalmitin are present, as is shown by analysis of the glycerides isolated from the alcohol-soluble portion of hydrogenated butter fat. The author has also isolated another glyceride, m.p. 67.9° C., from butter fat; this glyceride yielded a mixture of fatty acids, m.p. 55.5° C.—W. P. S.

Purine bases in foodstuffs; Estimation of —. T. von Fellenberg. Biochem. Zeits., 1918, 85, 323—336.

TABLES are given showing the content of purine bases in a large number of foodstuffs. The purine bases were precipitated as enpurous compounds by a method described in detail by the author, and the nitrogen was estimated in this precipitate. (See also J. Chem. Soc., Oct., 1918.)—S. B. S.

Edible oils and fats; Treatment of — and the production of butter substitutes. C. Townsend, London. Eng. Pat. 117,104, June 2, 1917. (Appl. No. 7944 of 1917.)

WHEY, preferably obtained as a by-product from butter and cheese making, is evaporated, and the residue dried and powdered for storage. For imparting a butter flavour the powder is mixed with water to the consistency of cream, and soured with lactic bacteria at a suitable temperature, or a suitable amount of lactic acid may be mixed with the whey powder. The product is then incorporated in an emulsifier in suitable proportion, and at an appropriate temperature, with oils, fats, or margarine.—C. A. M.

Grain; Method of decolorising —. W. Frick, Höchst, Germany, Assignor to General Electric Co. U.S. Pat. 1,267,204, May 21, 1918. Date of appl., Jan. 8, 1915.

GRAIN which has become wet and musty is subjected to the action of a mixture of ozone and steam, and then dried in fresh air.—W. P. S.

Juice-asepticising process. H. Coffman, Nazareth, Pa. U.S. Pat. 1,270,698, June 25, 1918. Date of appl., Apr. 16, 1917.

FRUIT JUICE, immediately after it has been extracted from the fruit, is placed in bottles, carbon dioxide is introduced into the latter to displace the air, the bottles are sealed, heated in water at 145° F. (63° C.), then cooled, and, after the lapse of 48 hrs., again heated at the same temperature for 15 mins.—W. P. S.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Determination of magnesia in —. M. Monhaupt. Chem.-Zeit., 1918, 42, 338.

A FEW drops of methyl orange solution are added to 100 c.c. of the water, the latter is neutralised in the cold, 5 c.c. of 3% potassium oxalate solution and a known excess of N/10 alkali solution (equal volumes of N/10 sodium hydroxide and carbonate solutions) are added, and the mixture is diluted to 200 c.c. The quantity of sodium hydroxide added must be more than that of the magnesia present in the water. After filtration, 100 c.c. of the filtrate is treated with 5 c.c. of 2% neutral calcium chloride solution and then titrated, without filtration of the calcium oxalate and carbonate, with N/10 acid.—W. P. S.

Phosphoric acid; Colorimetric estimation of — in potable water. P. N. van Eck. Pharm. Weekblad, 1918, 55, 1037—1040.

Stannous chloride can replace hydrazine sulphate in Riegler's colorimetric method of estimating phosphoric acid (this J., 1915, 796), the same blue coloration being produced.—A. J. W.

Permutite; Basic exchange in —. V. Rothmund and G. Kornfeld. Z. anorg. Chem., 1918, 103, 129—163.

The basic exchange which takes place between hydrated aluminosilicates, such as the soil zeolites or the artificial product permutite, and neutral salt solutions is a true chemical action and not a process of adsorption. In the case of permutite, equilibrium is rapidly established between the solid and a neutral salt solution, and the composition of the resulting permutite is found to depend upon the relative concentrations of the interchangeable basic radicals in solution. (See also J. Chem. Soc., 1918, II., 315.)—E. H. R.

Trypaflavin solutions; The keeping properties of —. A. Abelmann. Pharm. Zeit., 1918, 63, 270.

The yellow dyestuff Trypaflavin (diaminomethyl-acridinium chloride) is employed therapeutically in the form of a 0.1% solution as a bactericide which is comparatively non-toxic to animal tissues and preserves its activity in presence of serum. The 0.1% solution is extremely sensitive to strong sunlight; it turns brown after exposure for one day, and the brown colour slowly increases on further exposure to light. A solution exposed to light and left open to the air for a month was found to be dark brown in colour and to have developed a growth of *Actinomyces*, in spite of the fact that some of the Trypaflavin was still undecomposed. With the addition of sodium carbonate, sulphite, or chloride, decomposition takes place with the formation of a brownish precipitate, but the liquid remains bright yellow on exposure to light. Trypaflavin solutions keep perfectly well in the dark, and decompose only slowly in diffused daylight; 1% solutions are considerably more stable than 0.1% solutions. Addition of acetic or citric acid or of hydrogen peroxide produces the brown coloration even in the dark, and must therefore be avoided. Adequate protection from light by the use of dark-coloured bottles and preservation in the form of more concentrated solutions are recommended.—J. F. B.

PATENTS.

Water-distilling apparatus. G. B. Furman, East Orange, N.J. U.S. Pat. 1,268,223, June 4, 1918. Date of appl., Aug. 25, 1915.

The apparatus consists of a main tank and two auxiliary tanks, together with a device for maintaining a constant level of water in the tanks. Steam from a boiler is conducted to a coil in the main tank, connected with a second coil in the first auxiliary tank. A coil in the second auxiliary tank serves to condense water vaporised from the main and first auxiliary tanks. The condensed water from the three coils is collected in a common receiver.—W. P. S.

Antiseptic dressing. W. R. Walkey, Westminster. Eng. Pat. 117,750, Oct. 19, 1917. (Appl. No. 15,222 of 1917.)

Cotton wool, fibre, or other suitable material is first treated with a solution of paraffin wax or mixture of waxes in ether or other suitable solvent, and, after the solvent has been driven off, with a solution of Flavine or other dye which has an antiseptic action.—L. A. C.

Purifying fluids [e.g., drinking water]; Process for —. B. Schwerin, Assignor to Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. U.S. Pat. 1,269,006, June 11, 1918. Date of appl., Dec. 4, 1916.

Evaporating and distilling apparatus [for water]. Eng. Pat. 111,480. See I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Strophanthus seeds; The sulphuric acid test for —. P. Bohrisch. Pharm. Zeit., 1918, 63, 318—319.

The sulphuric acid test for strophanthin, by which a green coloration is obtained immediately with the officinal (Kombé) variety of strophanthus seed, has not been very accurately specified. Especially when the word "cross-section" is interpreted to mean the surface of a seed which has been cut in half, the indications of the test are very variable and indefinite. The author has investigated the various modifications of the test which have been proposed, and recommends the following procedure:—Thin cross-sections of the seeds are placed on an object glass and treated with a little ether to remove the fat; they are then covered with one drop of sulphuric acid which has been diluted with one-fourth of its weight of water. The endosperm and at least the outer portions of the embryo leaves should show a deep green coloration, which is best observed under a low-power microscope or a strong magnifying glass.—J. F. B.

Alkaloids of the pomegranate tree. V. Resolution of pelletierine and methylisopelletierine into their optical antipodes. Elucidation of Tanret's bases. K. Hess and A. Eichel. Ber., 1918, 51, 741—747.

PELLETIERINE and methylisopelletierine have been resolved by means of active tartaric acids. Some optically-active modifications of these bases were described by Tanret as occurring among the alkaloids of the pomegranate, but the constants quoted by him were much higher than those now observed. The authors feel more than ever justified, therefore, in their statement that no active modifications are present in the root. (See further J. Chem. Soc., 1918, I., 404.)—J. C. W.

Arceaidine and arceoline; New method for preparing —. Elucidation of the constitution of guvacine and arceaine. Synthesis of 1-methyltetrahydropyridine-carboxylic acids. I. K. Hess and F. Leibbrandt. Ber., 1918, 51, 806—820.

WHEN the 1-methylpiperidine-carboxylic acids are brominated in alcohol and the products are heated with sodium ethoxide, 1-methyltetrahydropyridine-carboxylic acids are produced. These are closely related to the alkaloids of the areca nut. For example, arceaidine is 1-methyl-1,3,5,6-tetrahydropyridine-3-carboxylic acid, and arceoline is its methyl ester, and these may be obtained by the above method from methyl 1-methylpiperidine-3-carboxylate (N-methylnipecotinate). Two other alkaloids have been found in the areca nut, namely, the acids guvacine and its N-methyl-derivative, arceaine. The authors have synthesised 1-methyl-1,4,5,6-tetrahydropyridine-2-carboxylic acid from 1-methylpiperidine-2-carboxylic acid (N-methylpilocolic acid), but have found that whilst this closely resembles arceaine it is not identical with it. When guvacine is hydrogenated with the aid of colloidal

platinum, however, it yields piperidine-4-carboxylic acid. Consequently, guvacine is a tetrahydropyridine-4-carboxylic acid, probably the 1.2.5.6 derivative.

In another paper (Ber., 1918, 51, 1004—1006), Hess shows that the methyl ester of guvacine, "guvacoline," is also present in the areca nut.

On the other hand, Freudenberg (*ibid.*, 976—982) submits evidence to the effect that guvacine is simply demethylated arecaldine, in which case arecaine and arecaldine are identical. (See further J. Chem. Soc., i., 403.)—J. C. W.

Catalysts; Influence of foreign substances on the activity of —. IV. *Experiments with palladium hydrosol in the presence of mercury and mercuric oxide.* C. Paal and W. Hartmann. Ber., 1918, 51, 711—737.

The influence of mercury on the absorptive power of palladium was known even to Dulong and Thénard, and since the advent of colloidal solutions of the platinum metals as catalysts, mercury salts have been classed with the anti-catalysts. In the course of the present work, however, it has been found that palladium hydrosol, protected by sodium protalbate, permanently loses its power of activating hydrogen, and thus stimulating processes of reduction of all kinds, if it is left in contact with mercury, and especially yellow mercuric oxide, but that such a preparation has practically undiminished influence on hydrogen peroxide. A long series of experiments is described which prove that the inactivation of the colloidal palladium is due to its power of sending mercury or its oxide into colloidal solution. This power of "peptisation" is not exerted by sodium protalbate, at any rate on free mercury, although mercuric oxide is taken up if shaken with the salt in an atmosphere of hydrogen.—J. C. W.

Hydrogenation of aromatic compounds with the help of platinum. III. *Hydrogenation with platinum containing oxygen.* R. Willstätter and D. Jaquet. Ber., 1918, 51, 767—779.

Users of platinum in catalytic reductions have begun to recognise that it sometimes matters whether the catalyst is entirely free from occluded oxygen at the outset or has been freely exposed to the air. For example, Hess (Ber., 1913, 46, 3120, 4104) has shown that the rigid exclusion of oxygen is necessary in order to ensure success in the reduction of pyrrole and some of its derivatives. The present paper, however, describes cases of the opposite kind, in which the catalyst must be occasionally activated by exposing it to oxygen. The most interesting example is phthalic anhydride. If this is dissolved in glacial acetic acid and treated with hydrogen in the presence of platinum-black, only a small volume of gas is absorbed, unless the apparatus is opened as occasion requires and the catalyst is agitated in contact with the air. Then the reduction proceeds smoothly by way of phthalide and *o*-toluic acid, to hexahydrophthalide, hexahydro-*o*-toluic acid, and hexahydrophthalic acid. Indeed, the influence of phthalic anhydride is such that it even inhibits the hydrogenation of benzene and phthalic acid under ordinary conditions. It appears, therefore, that platinum and oxygenated platinum must be regarded as distinct catalysts. In the case of phthalic anhydride, it is obvious from the above that the oxygen-ring is attacked before the benzene nucleus, but in the case of phthalimide the sole product is hexahydrophthalimide, the side ring remaining intact. The reduction of indole to the utmost limit, represented by octahydroindole ("perhydroindole"), is also described. (See further J. Chem. Soc., 1918, i., 391.)—J. C. W.

Selenium derivatives of antipyrine; New —. [Determination of selenium in organic compounds.] F. von Konek and O. Schleifer. Ber., 1918, 51, 842—855.

SELENIUM monochloride reacts with antipyrine as though it had the constitution, $\text{Se}:\text{SeCl}_2$, giving diantipyryl diselenide (or "selenoselenide"),

This deposits selenium on boiling with hydrochloric acid, giving diantipyryl selenide (compare Ger. Pat. 299,510). Selenium tetrachloride reacts to form diantipyrylselenium dichloride $(\text{C}_{11}\text{H}_{11}\text{ON}_2)_2\text{SeCl}_2$.

The methods for estimating selenium in organic compounds are reviewed, none being found quite satisfactory. The above compounds were analysed by digesting them with pure sulphuric acid (10 c.c. for 0.2 grm.) until a brownish-green colour developed, then diluting to about 200 c.c., saturating with sulphur dioxide, and collecting the precipitated selenium next day. The drawback to this method is the difficulty of determining when to stop the action of the sulphuric acid, as it should not proceed so far that much selenious acid is produced. (See further J. Chem. Soc., 1918, i., 407.)—J. C. W.

"Perka-glycerol." [Potassium lactate solution.] P. Panwitz and A. Beythien. Z. Unters. Nahr. Genussm., 1918, 35, 385—387.

A GLYCEROL substitute sold under the name "Perka-glycerol" consists of an aqueous solution containing 65—68% of potassium lactate.—W. P. S.

Acetone; Detection of —. I. M. Kolthoff. Pharm. Weekblad, 1918, 55, 1021—1029.

IN Frommer's test for acetone (Berl. Klin. Wochenschr., 1902, 42, 1005), salicylaldehyde can be replaced by vanillin, but not by acetaldehyde or formaldehyde.—A. J. W.

Keeping properties of Trypaflavin solutions. Abellmann. See XIXB.

Detection of glycuronic acid and other acids with similar behaviour by the naphthoresoreinol reaction. Van der Haar. See XXIII.

Combined estimation of tyrosine and uric acid in the same solution. Herzfeld and Klinger. See XXIII.

PATENTS.

Glandular extractive product and process of manufacturing same. T. B. Aldrich, Assignor to Parke, Davis & Co., Detroit, Mich. U.S. Pat. 1,271,111, July 2, 1918. Date of appl., Mar. 3, 1913.

THE infundibular lobe of the pituitary gland is dehydrated and freed from fat, and then extracted with glycerin. By the addition of a suitable precipitant (alcohol or acetone) to the extract, a substance is precipitated possessing pressor and "oxytocic" properties.—L. A. C.

Di[hydr]oxydiaminoarsenobenzene; Metallic derivatives of —. J. Danyś, Sevres, France. U.S. Pat. 1,269,792, June 18, 1918. Date of appl., July 28, 1916.

SEE Eng. Pat. 104,496 of 1916; this J., 1917, 906.

XXII.—EXPLOSIVES; MATCHES.**PATENT.**

Explosive materials; Machine for making pellets from pulverulent or granular — T. M. Creischere, Glasgow, and R. G. Creischer, Clarkston, Renfrew. Eng. Pat. 117,901, Dec. 15, 1916. (Appl. No. 18,034 of 1916.)

XXIII.—ANALYSIS.

Analysis; New method of qualitative — without the use of hydrogen sulphide. G. Almkvist. Z. anorg. Chem., 1918, 103, 221–239.

A new method of qualitative analysis is described in some detail. Although it does not effect a quantitative separation of the different groups and subgroups, it is claimed that all the commoner metals can be readily detected. The principal group reagent is a mixture of potassium hydroxide, potassium carbonate, and hydrogen peroxide. The elements of group I., soluble in this reagent, are As, Sb, Sn, Pb, Zn, Al, and Cr; the elements of group II., insoluble in the reagent, are Ag, Hg, Bi, Fe, Mn, Cu, Cd, Ni, Co, Ca, Sr, Ba, and Mg; group III. comprises the alkali metals and ammonia. Full details for the detection of each metal in the three groups are given. (See also J. Chem. Soc., 1918, II., 333.)—E. H. R.

Barium; Volumetric determination of — and the solubility of barium chromate in various aqueous solutions. J. Waddell. Analyst, 1918, 43, 287–289.

Barium chromate, as obtained in the separation of barium from calcium and strontium, may be dissolved in hydrochloric acid and determined volumetrically by a method similar to that used for lead. $2\text{H}_2\text{CrO}_4 + 12\text{HCl} + 6\text{KI} = 6\text{KCl} + 2\text{CrCl}_3 + \text{SiH}_2\text{O} + 3\text{I}_2$. The solution of the barium salt is treated with 30% ammonium acetate solution (10 c.c. to 50 c.c. of a 0.3% solution of barium chloride), and the barium precipitated by adding 15 c.c. of 10% ammonium bichromate to the boiling liquid. The precipitate is washed, dissolved in a mixture of 25 c.c. of strong hydrochloric acid and 75 c.c. of water, and the solution made up to 200 c.c., treated with 6 grms. of potassium iodide, and allowed to stand for 10 mins. The liberated iodine is then titrated with standard thiosulphate solution. This method was used to determine the solubility of barium chromate in water and various aqueous solutions, the following results being obtained:—Water, 0.78; 1% ammonium acetate solution, 2.80; 10% ammonium acetate, 3.58; 20%, 5.07; 10% ammonium nitrate, 4.89; 10% sodium chloride, 2.39; and 1% acetic acid, 11.04 parts per 100,000 of washing liquid. Water is thus the best medium for washing precipitated barium chromate.

—C. A. M.

Manganese; Microchemical reaction for —. J. B. Menke. Chem. Weekblad, 1918, 15, 868–869.

MANGANESE sulphate gives with a drop of ammonia containing cyanuric acid a precipitate of manganous hydroxide. After the lapse of a few minutes, or immediately on boiling, colourless unstable needles of high polarising power separate from the mixture.

—A. J. W.

Bismuth; Electro-analysis of — without platinum electrodes. P. Poch. Anal. Fis. Quim., 1918, 16, 520–533.

THE author has devised a method of estimating bismuth electrolytically. It can be carried out in solution in nitric, tartaric, sulphuric or acetic acid, and also in ammoniacal solution. The experiments were made with platinum electrodes, with a platinum anode and a copper cathode, with a platinum

cathode and an iron or graphite anode, and with a copper cathode and an iron or graphite anode.

—A. J. W.

Molybdenum; Determination of —. K. Wolf. Z. angew. Chem., 1918, 31, 140.

THE conversion of a precipitate of molybdenum sulphide into MoO_3 by ignition is not quantitative if the temperature rises above 450°C ., as sublimation then occurs to an appreciable extent. A temperature of 400°C . suffices and it is most convenient and certain to ignite the precipitate in an electrically heated furnace at a temperature of 425°C .

—H. J. H.

Carbon monoxide; Behaviour and detection of the smallest quantities of — in the "chlorate" pipette. K. A. Hofmann and H. Schibsted. Ber., 1918, 51, 837–842.

AN absorption-pipette for hydrogen has previously been described (this J., 1916, 1002, 1003), which contains porous tubes impregnated with platinum and a little palladium, partially immersed in a solution of sodium chlorate activated by osmium tetroxide. The rate at which hydrogen is oxidised in this pipette is greatly lessened by traces of carbon monoxide, but inasmuch as the active surface of the platinumised tubes becomes smaller as the absorption proceeds and the liquid rises, a direct observation of the rate of absorption does not give a true idea of the influence of carbon monoxide. As the part of the pipette in which the tubes are packed is cylindrical, the active area is proportional to the volume of gas unabsorbed, so it is possible to arrive at a "relative rate of absorption" at any period. With pure hydrogen, this rate is constant, or slowly rises, until half the gas is absorbed, whereas traces of carbon monoxide cause very rapid falls in this rate. If the pipette is standardised, therefore, and a curve is plotted connecting the relative rates of absorption at "half volume" with various proportions of carbon monoxide, the phenomenon can be adapted to analytical purposes.—J. C. W.

Distilling in [superheated] steam under reduced pressure; Laboratory apparatus for —. C. Harries and R. Haarmann. Ber., 1918, 51, 788–790.

IN the apparatus, which is fully described with diagrams, steam at 3–4 atmos. pressure is admitted through a throttle-valve into a superheating chamber kept at about 300°C ., and then into the substance in the evacuated distillation flask. The vapours from the distillation flask pass through a wide tube partly filled with short pieces of glass tubing in order to prevent foaming and spraying over of liquid into the condenser.—J. C. W.

Glycerol; The copper method for estimating —. F. L. Weiss. Chem. Weekblad, 1918, 15, 862–868.

THERE is no definite chemical compound of copper and glycerol, the proportion of copper in the glycerol-copper complex being determined by four factors, *viz.*, the proportion of glycerol in the solution, the copper content increasing with the glycerol; the temperature, the proportion of copper falling with rise of temperature, especially in very dilute solutions; the degree of dilution of the liquid, and the concentration of the free alkali.—A. J. W.

d-Glycuronic acid and other acids with similar behaviour; Detection of — by the naphthoresorcinol reaction. A. W. Van der Haar. Biochem. Zeits., 1918, 88, 205–212.

THE substance is first hydrolysed with 5% sulphuric acid, and the solution neutralised with

barium hydroxide, filtered and concentrated. Lead acetate is then added, and after filtration basic lead acetate. The glycuronate is contained in the precipitate thus produced, which is heated with 10 c.c. of 10% hydrochloric acid and 100 mgrms. of naphthoresorcinol for 1 minute. After cooling to 50° C. the solution is shaken with benzene; if glycuronic acid is present a violet colour is produced in the benzene, which can be characterised by a band in D in the spectrum. (See also J. Chem. Soc., Oct., 1918.)—S. B. S.

Tyrosine and uric acid: Combined estimation of — in the same solution. E. Herzfeld and R. Klinger. *Biochem. Zeits.*, 1918, **88**, 283—285.

THE two substances are estimated together by Folin's phenol reagent, the tyrosine giving a colour twice as strong as the corresponding amount of uric acid. The latter is then destroyed by hydrogen peroxide and sodium hydroxide, and, under specified conditions, the phenol reagent is added again, and the tyrosine alone estimated. (See also J. Chem. Soc., Oct., 1918.)—S. B. S.

PATENT.

Viscosity measuring instrument. H. R. Edgecomb, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,270,800, July 2, 1918. Date of appl. Aug. 11, 1913.

AN apparatus for measuring the viscosity of heavy oil or grease comprises a vertical jacketed cylinder containing the material to be tested, provided with

a piston supported by an external adjustable spring above it. The cylinder is moved axially at a uniform rate by means of a hydraulic cylinder below it, and the time of its movement is recorded. A record sheet is attached to the cylinder, and the vertical movement of the piston, as modified by the viscosity of the fluid and the resistance of the spring, is transformed by a bell crank lever into a horizontal movement and recorded on the moving sheet.—W. F. F.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Adams. Furnaces. 14,977. Sep. 14.
Baily and Cope. 14,400. *See X.*
Bawtree and Hadfield. Apparatus for applying thick coating of fluid, etc., material to the interior surfaces of cylinders. 14,579. Sep. 7.
Beale and Dmckerley. Refrigeration. 14,875. Sep. 12.
Candlot. Kilns or shaft furnaces. 14,468. Sep. 5. (Fr., Mar. 23, 1917.)
Ely. Furnaces. 14,647. Sep. 9.
Hutchins. Means for treating gases with liquids. 14,933. Sep. 13.
McIntyre, and Milne and Son. Means for drying, concentrating, and filming solids, liquids, semi-liquids, etc. 14,230. Sep. 2.
Nederlandsche-Maatschappij. 14,447. *See XIX.*
Roberts. Kilns or furnaces. 14,791. Sep. 11.
Saunders and Walsh. 14,422. *See II.*
Stein et Cie. Oscillating furnaces. 14,248. Sep. 2. (Fr., Oct. 24, 1917.)
Stein et Cie. Continuous re-heating furnaces. 14,796. Sep. 11. (Fr., Nov. 5, 1917.)
Stewart. Filtration apparatus. 14,367. Sep. 4.
Thomson. Colour-heat insulation. 15,001. Sep. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,620 (1917). Savage, and Brinjes and Goodwin. Edge-runners, pan and like mills. (118,465.) Sep. 11.
13,413 (1917). Rimmer. *See XIX.*
18,620 (1917). Norton. Grinding-machines. (118,537.) Sep. 11.
4800 (1918). Moore. Apparatus for agitating liquids, powders, granular substances, etc. (118,567.) Sep. 11.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Bailey. Method of treating peat, etc., by superheated steam. 14,204. Sep. 2.
Bargate and Desmond. Desulphurising gaseous distillates. 14,955. Sep. 14.
Chance. Washing coal and concentrating ores and minerals. 14,645. Sep. 9. (U.S., Aug. 27, 1917.)
Clark. Method of treating oils. 14,658. Sep. 9.
Hart. Suction-gas scrubbers and coolers. 14,349. Sep. 4. (Australia, Aug. 28, 1917.)
Hart. Suction-gas plants. 14,628. Sep. 9. (Australia, Nov. 13, 1917.)
Hes. 14,663. *See X.*
Jackson, and Woodall and Duckham. Manufacture of gas in vertical retorts. 14,712. Sep. 10.
Jackson and Spicer. Liquid fuel for internal-combustion engines. 14,830. Sep. 12.

Mantle. Treating waste, etc., lubricating oils to eliminate sulphur and other impurities. 14,673. Sep. 10.

Nitrogen Products and Carbide Co., and Perkin. Destructive distillation of carbonaceous materials. 14,519. Sep. 6.

Saunders and Walsh. Purification of gases. 14,422. Sep. 5.

Soc. Franco-Belge de Fours à Coke. Flue-bases or piedroits for coking ovens. 14,725. Sep. 10. (Fr., Oct. 22, 1917.)

Stafford. Destructive distillation of wood. 14,708. Sep. 10. (U.S., Sep. 10, 1917.)

Stewart. Explosive substances for internal-combustion engines, etc. 14,283. Sep. 3.

White (Sinclair Refining Co.). Cracking hydrocarbons. 14,865. Sep. 12.

White. Distillation of solid carbonaceous material. 14,773. Sep. 11.

Wilton. Gas plant, coking plant, etc. 14,408. Sep. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

12,866 (1917). Ore. Coke ovens. (118,470.) Sep. 11.

13,049 (1917). Dowson and Mason Gas Plant Co., and Webb. Open-hearth gas-producers, etc. (118,689.) Sep. 18.

15,923 (1917). Marbais and Deguide. Extraction and fractional distillation of oils from coal gas. (118,730.) Sep. 18.

17,054 (1917). Hillen. Distillation of coal and other materials for manufacture of motor gas. (118,522.) Sep. 11.

717 (1918). Merz and McLellan, Michie, and Weeks. Solid fuel for large-scale power production. (118,777.) Sep. 18.

4504 (1918). Dempster and Sons, and Brooke. Horizontal and inclined retort settings. (118,804.) Sep. 18.

III.—TAR AND TAR PRODUCTS.

COMPLETE SPECIFICATIONS ACCEPTED.

12,621 (1917). Nicorestl. Solid preparations containing cresols and mixtures of cresols, and manufacture thereof by means of salts of fatty acids. (118,667.) Sep. 18.

15,421 (1917). Bull. Sulphonation of aromatic hydrocarbons. (118,727.) Sep. 18.

15,923 (1917). Marbais and Deguide. *See* II.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATIONS ACCEPTED.

12,348 (1917). Imray (Soc. Chem. Ind. in Basle). Manufacture of azo dyestuffs capable of being chromed. (118,448.) Sep. 11.

16,246 (1917). Allsebrook. Manufacture of organic colouring matter and of pigments therefrom. (118,735.) Sep. 18.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Ashton. Manufacture of paper, papier mâché, etc. 14,961. Sep. 11.

Marks (Cedaroid Co.). Paper or paper board and its manufacture. 14,784. Sep. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

8206 (1917). Lippitt. Obtaining fibres from fibrous material or vegetable matter. (113,081.) Sep. 18.

16,038 (1917). Doverdale. Paper-making machines. (118,511.) Sep. 11.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Barnes, Wrigley, and Spence and Sons. Dyeing, staining, and mordanting. 14,710. Sep. 11.

Furrell. Dye jigs. 14,383. Sep. 4.

COMPLETE SPECIFICATION ACCEPTED.

16,508 (1917). Dudley. Dyeing machines. (111,843.) Sep. 11.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Bargate and Desmond. 14,955. *See* II.

Craig. Obtaining potash compounds from blast furnace, etc., slag. 14,412. Sep. 5.

Dawson. Manufacture of nitric acid. 14,359. Sep. 4.

Dawson. Production of sodammonium sulphate from nitre cake, etc. 14,756. Sep. 11.

Ffabetti. Manufacture of platinised asbestos. 14,325. Sep. 3. (Italy, Nov. 5, 1917.)

Marks (Du Pont de Nemours and Co.). Concentrating nitric acid. 14,522. Sep. 6.

Rabinovitch. Extraction of magnesium compounds. 14,556. Sep. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

12,594 (1917). Maconochie and de Ros. *See* X.

12,595 (1917). Maconochie and de Ros. Production of zinc oxide. (118,665.) Sep. 18.

14,425 (1917). Hutchins. Apparatus for drying salt. (118,712.) Sep. 18.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

British Thomson-Houston Co., and Gray. Devices for discharging predetermined quantities of glass from glass furnaces. 14,862. Sep. 12.

Kraus. Manufacture of refractory material. 14,542. Sep. 6.

Winwood. Pot or receptacle for heating or melting glass. 14,434. Sep. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

13,845 and 13,846 (1917). Crowell. Dental cements. (118,701 and 118,702.) Sep. 18.

8472 (1918). McCauley. Means for discharging molten metal in the manufacture of glass articles. (118,581.) Sep. 11.

9030 (1918). McCauley. Conveyance of molten glass. (118,585.) Sep. 11.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Swingler. Mixing-machine for concrete, etc. 14,691. Sep. 10.

Thermalloy, Ltd., and Vautin. Sulphur cements. 14,847. Sep. 12.

Waine. Manufacture of bricks and artificial stones. 14,869. Sep. 12.

Wingvist. Rotating kilns for burning cement, etc. 14,625. Sep. 9. (Sweden, June 12.)

COMPLETE SPECIFICATION ACCEPTED.

216 (1918). Ardagh. Manufacture of fire-resisting plastic material and its application to constructional purposes. (118,768.) Sep. 18.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Alpha Products Co. Manufacture of metallic cerium, etc. 14,238. Sep. 2. (U.S., Sep. 1, 1917.)

Baily and Cope. Melting-furnaces. 14,400. Sep. 4. (U.S., Sep. 4, 1917.)

Barfield and Peakman. Determination of decalescence in treatment of steel. 14,797. Sep. 11.

Besford and Day. Soldering aluminium, duralumin, etc. 14,979 and 14,980. Sep. 14.

Bolitho. Roasting and refining tin. 14,233. Sep. 2.

Chance. 14,645. *See* II.

Craig. 14,442. *See* VII.

Dehn (National Lead Co.). Smelting-furnace. 14,246. Sep. 2.

Frankignoul. Blast furnaces. 14,694. Sep. 10.
Gill (Fansteel Products Co.). Cleaning and circulating system for reducing tungsten trioxide. 14,614. Sep. 9.

Giton. Furnace for re-fusing and refining metal. 14,621. Sep. 9.

Hes. Metallic alloys for explosive, incendiary, or illuminating purposes. 14,663. Sep. 10.

Neill. Casting steel ingots. 14,481. Sep. 6.

Paetschke. Alloys and method of purifying same. 14,575. Sep. 7.

Stein et Cie. 14,796. See I.

COMPLETE SPECIFICATIONS ACCEPTED.

8366 (1917). Greaves and Etchells. Converting iron ores directly into steel. (118,647.) Sep. 18.

12,594 (1917). Maconochie and de Ros. Oxidation of tin. (118,664.) Sep. 18.

16,072 (1917) and 1905 (1918). Wild and Barfield. Indicating condition of steel, iron, etc., during heat treatment. (118,732.) Sep. 18.

17,367 (1917). Gaunt, Brookfield, and Tylor and Sons. Smelting furnaces and the like. (118,750.) Sep. 18.

6271 (1918). Ramen. Mechanical roasting-furnaces. (118,812.) Sep. 18.

7667 (1918). Clevenger. Electrolytic production of zinc. (115,817.) Sep. 18.

8289 (1918). Milliken. Alloys and process of making same. (118,825.) Sep. 18.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Angold and Railing. Electro-magnetic control of electric arcs. 14,965. Sep. 14.

Bibby. Electric-arc furnaces. 14,235. Sep. 2.

Bradley. Electrical treatment of gases. 14,943. 14,944. and 14,947. Sep. 13. (U.S., June 21, 1916.)

Fuller Accumulator Co., and Jones. Electrodes for primary and secondary batteries. 14,859. Sep. 12.

Kayser and Macdonald. Means for improving conductivity at joints of electrodes. 14,372. Sep. 4.

Pearson and White. Electric accumulators. 14,530. Sep. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

9489 (1917). Berry. Treatment of magnetic material for use in static transformers and other electrical apparatus. (118,425.) Sep. 11.

12,566 (1917). Worsnop. Electric accumulators (118,464.) Sep. 11.

13,472 (1917). Hamilton, Blackwell, and Turner. Electrodes for electric furnaces, etc. (118,690.) Sep. 18.

7667 (1918). Clevenger. See X.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Clark. 14,658. See II.

Naaml. Vennootsch. Jurgens' Vereen. Fabr. 14,329. See XIX.

Phillips. Extraction of oil from cottonseed. 14,537. Sep. 6.

COMPLETE SPECIFICATION ACCEPTED.

PATENTS.

Separating dust or powder from gases or air containing it; Apparatus for —. P. O. Rowlands, Liverpool. Eng. Pat. 117,957, Aug. 13, 1917. (Appl. No. 11,593 of 1917.)

SEVERAL sets of pervious vertical tubes provided with crossheads near the top are connected by flexible portions above the crossheads to an upper horizontal trunk. The tubes are arranged within a casing which is provided with doors on each side to allow access to the tubes, the lower ends of which are connected to a trunk provided with a screw conveyor for removing deposited dust. The tubes are provided at their upper ends with spring valves and with shaking tappets which are operated by a series of cams and levers.—W. H. C.

Air-washer. D. T. Hastings, Assignor to Holley Bros. Co., Detroit, Mich. U.S. Pat. 1,272,434, July 16, 1918. Date of appl., Mar. 8, 1917.

THE washing liquid is contained in a receptacle having an air inlet and outlet. By means of a float the air inlet is maintained in constant relation to the level of the washing liquid and is closed when the liquid has fallen to a predetermined level. Means are provided for separating liquid from the air in the space above the liquid level, and fresh liquid is introduced through a "filler," so placed that liquid is limited to a level below the separating device. The "filler" has a removable closure, and may be used as an auxiliary air inlet when the normal air inlet is cut off.—J. H. P.

Dust collector. F. A. Marascio, Phillipsburg, N.J. U.S. Pat. 1,272,489, July 16, 1918. Date of appl., Feb. 14, 1918.

THE apparatus comprises a casing with a door and a water pan which can be removed through the door. The dust-laden air is conducted through a hollow shaft into a perforated drum which rotates in the water in the pan.—J. H. P.

Gases; Art of separating materials from —. E. R. Knowles, Brooklyn, N.Y. U.S. Pat. 1,273,791, July 23, 1918. Date of appl., Feb. 14, 1917.

A MIXTURE of gas and heavier material is passed through a stationary chamber containing a centrifugal fan. Each fan blade consists of a solid or perforated radial portion, and a perforated circumferential portion extending towards but not reaching the next blade.—W. F. F.

Transmission or exchange of heat; Apparatus for the —. A. H. Bruce and C. Baynes, London. Eng. Pat. 118,375, Nov. 28, 1917. (Appl. No. 17,609 of 1917.)

AN apparatus for the transmission of heat between fluids, e.g., steam, water, or air, comprises an endless circular pipe, E, with inlet and outlet connections, D, at opposite ends of a diameter. The pipe is provided with a short external cylindrical flange, C, co-axial with the axis of the pipe ring, and projecting on both sides of the pipe. Semicircular ribs, A, and B, are provided on both sides of the flange. The provision of the flange, C, facilitates

the casting of the apparatus in one piece with a larger number of ribs, A, than the number of ribs, B, so as to equalise the spacing as shown.

—W. F. F.

Crusher. W. K. Liggett, Assignor to The Jeffrey Manufacturing Co., Columbus, Ohio. U.S. Pat. 1,268,479, June 4, 1918. Date of appl., July 28, 1914.

THE material is fed from a hopper to the upper part of the space between a rotary crushing roll and a breaker plate with a concave working surface mounted at one side of the roll. The plate is pivoted at its lower end and held yieldingly against the material being crushed. The upper end of the plate is connected with gearing by which the plate can be moved downwards, inwards, outwards, and upwards, and has a projection which moves the material towards the crushing roll.

Tube-mills; Feeder for —. H. W. Hardinge, New York. U.S. Pat. 1,272,801, July 16, 1918. Date of appl., May 11, 1916.

THE material is fed into the axial inlet opening of a tube-mill from a rotary conical casing having an internal helico-spiral trough conveyor.—W. H. C.

Mixing apparatus; Chemical —. J. R. Milson, Watertown, Mass., Assignor to J. J. Burns, Boston, Mass. U.S. Pat. 1,267,102, May 21, 1918. Date of appl., Nov. 13, 1916.

THE apparatus comprises a number of containers connected with a mixing chamber by pipes provided with weighted valves so that, when the containers are heated, a predetermined pressure may be generated in each. Gases or vapours leave the containers under pressure and pass to the mixing chamber, which is provided with an agitator, and thence flow to a water-cooled reservoir or condenser.—J. H. P.

Mixer and dryer. W. B. Ruggles, Bayonne, N.J. U.S. Pat. 1,269,120, June 11, 1918. Date of appl., Mar. 9, 1911.

MATERIAL to be mixed and dried is passed through a rotary mixer, and thence through a passage to an adjacent rotary dryer through which hot gas is also passed. The gas leaving the dryer is passed through an auxiliary heater to preheat the material. The passage between the mixer and dryer is controlled by a plate which may be operated during rotation of the apparatus to open or close the passage.—W. F. F.

Steam; Apparatus for the generation of —. P. E. Tucker, Bremerton, Wash. U.S. Pat. 1,270,990, July 2, 1918. Date of appl., July 25, 1917.

ALTERNATE charges of combustible gas and small quantities of water are delivered to a combustion chamber in such a manner that the burning gas converts the preheated water into steam and forces the latter into an adjacent reservoir.—A. B. S.

Filter. W. H. Duryea, Tiffin, Ohio. U.S. Pat. 1,271,681, July 9, 1918. Date of appl., Aug. 17, 1916.

A CYLINDRICAL porous filter chamber having one flat and one hemispherical end is contained within an outer casing of similar shape. The deposit which forms on the surface of the filter chamber is washed off by a multiple jet of liquid introduced through the centre of the curved end of the outer chamber and is discharged through a special outlet provided for the purpose.—W. H. C.

Filter. F. K. Atkins, New York, and E. F. Atkins, Arlington, N.J. U.S. Pat. 1,273,127, July 23, 1918. Date of appl., Sep. 18, 1917.

THE filter plates are provided with central openings and are arranged on a common axis. The solid material deposited on the plates is removed by a series of cutters mounted on a central shaft extending through the openings. The cutters are normally arranged in the spaces between the plates, in alignment with the central openings, and may be moved over the active surfaces of the plates by rotation of the shaft.—W. F. F.

Ammonia condenser for ice machines. W. H. Manns, Assignor to Frick Co., Waynesboro, Pa. U.S. Pat. 1,272,286, July 9, 1918. Date of appl., July 31, 1914.

THE condenser comprises a series of coils connected at the inlet end with an ammonia gas header and at the outlet end with a liquid ammonia header, both headers being arranged on a level with the top of the coil. A valve interposed near the gas inlet regulates the flow of liquid ammonia absorbed by the liquid in the inlet pipe outside of the valve.

—J. H. P.

Gas-absorption apparatus. H. B. Slater, Los Angeles, Cal. U.S. Pat. 1,272,321, July 9, 1918. Date of appl., Feb. 19, 1916.

THE apparatus comprises a casing having an inlet at the top and an outlet at the bottom for the absorbing liquid. A trough receives the liquid from the inlet and distributes it in a descending sheet, which is caught by a deflector and caused to form a second descending sheet. The outlet for the liquid is provided with aspirating means, and the gas to be absorbed is aspirated through the descending sheets of liquid.—J. H. P.

Fume condenser. G. C. Richards, Berkeley, Cal. U.S. Pat. 1,272,528, July 16, 1918. Date of appl., Apr. 30, 1917.

THE condenser comprises a long box-like structure with a number of vertical baffle plates. A number of frames covered with fabric are placed angularly between the baffle-plates and form a covering for the box. The fumes to be condensed are forced into the box and water is sprayed on the frames and into the box, and is kept at a constant level in the box.—J. H. P.

Conveyor for furnaces; Material —. T. B. Cram, Assignor to The Railway Materials Co., Chicago, Ill. U.S. Pat. 1,272,918, July 16, 1918. Date of appl., July 26, 1915.

THE hearth of the furnace has a number of narrow longitudinal slots communicating with relatively large chambers below which open at both ends to the atmosphere. Refractory elements are mounted on supports in these chambers and project into the slots, and are caused to move in an arcuate path upwards and forwards in the slots by means of eccentrics mounted at both ends of the hearth. Heating gases are supplied to the furnace, and the supports are cooled by air circulated through the chambers below the slots.—J. H. P.

Registering apparatus chiefly for use in registering the amount of feed of granular and like substances. J. E. Lea, Manchester. Eng. Pat. 118,333, Aug. 27, 1917. (Appl. No. 12,258 of 1917.)

Separation of suspended particles from gases; Process and apparatus for —. H. A. Burns, London. Eng. Pat. 118,334, Aug. 27, 1917. (Appl. No. 12,281 of 1917.)

SEE U.S. Pat. 1,250,088 of 1917; this J., 1918, 114 A.

Cooling, humidifying, and filtering air or the like; Apparatus for —. H. F. Brown, Sheffield. U.S. Pat. 1,271,271, July 2, 1918. Date of appl., Jan. 19, 1918.

SEE Eng. Pat. 112,653 of 1917; this J., 1918, 114 A.

Drying materials in sacks and the like; Method and apparatus for —. H. P. Dinesen, Herlev, Denmark. U.S. Pat. 1,271,293, July 2, 1918. Date of appl., Jan. 25, 1916.

SEE Eng. Pat. 100,697 of 1916; this J., 1916, 915.

Crystallisation; Apparatus for effecting continuous — from solutions. E. Hansen, Rjukan, Assignor to Norsk Hydro-Elektrisk Kvaestof-aktieselskab, Christiania, Norway. U.S. Pat. 1,273,058, July 16, 1918. Date of appl., Sep. 3, 1915.

SEE Fr. Pat. 479,668 of 1915; this J., 1916, 1145.

Emulsifying apparatus. U.S. Pat. 1,269,399. See XIXA.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal dust and air mixtures; Laboratory determination of explosibility of —. J. K. Clement and J. N. Lawrence. U.S. Bureau of Mines, Tech. Paper 141, 1917. 35 pages.

A LABORATORY method is described by which it is possible to determine whether dusts are capable of giving rise to explosions in the mine, and the percentage of pulverised shale that must be added to the dust to render it non-explosible. The method has been standardised against certain coal dusts of which the "ignition limit" and "propagation limit" mixtures with shale dust have been previously determined by large-scale experiments in the mine. The term "ignition limit" is used to designate the highest percentage of shale dust with which a given coal dust can be mixed and yet be ignited by the flame of a blown-out shot of black powder and give rise to an explosion. The "propagation limit" of a dust is the highest percentage of shale dust with which it can be mixed and still be capable

of propagating an explosion set up in a cloud of more inflammable dust or in an explosive gas mixture. The apparatus consisted of an explosion globe (capacity 1400 c.c.) with an electrically heated igniting coil at the centre, the temperature of the ignition coil being 1200° C. The dust to be tested was puffed up on to the coil from an injector connected to an oxygen cylinder. Standard quantities of 1 gm. or 3 grms. of dust were used, all dusts being pulverised to pass through a 200-mesh sieve. The pressure produced in the globe by the combustion of the dust was registered by a Crosby indicator, and was taken as a measure of the inflammability of the dust in question. Suitable arrangements were also made for determining the explosibility of dusts when the explosion globe contained a mixture of air plus a small percentage of natural gas. The pressures developed by different dusts varied from a few tenths of a pound to 20 pounds. By noting the pressures developed in the apparatus by 1 gm. or 3 grms. of the ignition or propagation limit mixtures of a standard coal (as determined in the experimental mine), and assuming that the similar limit mixtures of any other coal would develop the same respective pressures, it was possible to predict the explosibility of a coal, by determining the pressures developed by a series of its mixtures with shale dust under standard conditions. A small percentage of gas in the atmosphere rendered necessary the addition of more shale dust to make the coal dust mixture non-explosible. The relative inflammabilities of 600 coals, including road and rib dusts and shale dust mixtures, have been determined by the method. No definite relation was found between inflammability and chemical composition. The effect of size of particles of dust on explosibility is touched upon. A series of curves is given showing graphically the relation between inflammability and percentage of shale dust in the mixtures for several typical coals.—T. F. E. R.

Incombustible matter in coal and rock-dust mixtures in mines; Quick determination of — A. C. Fieldner, W. A. Selvig, and F. D. Osgood. U.S. Bureau of Mines, Tech. Paper 144, 1918. 36 pages.

A VOLUMETER method is described depending on the relative specific gravities of coal and rock dusts. It is rapid, and gives results of reasonable accuracy if calibrated for the prevailing constituents of the dust. The true sp. gr. of coal rarely varies beyond the limits of 1.25 and 1.35, while the sp. gr. of incombustible matter found or applied in mines varies from 1.9 (clay) to 5.0 (pyrite). A definite weight (15 or 20 grms.) of dust is introduced into the flask of a volumeter (essentially a specific gravity bottle having an extended calibrated stem); 25 c.c. of alcohol is allowed to flow on to the dust, and the mixture gently shaken until the air bubbles have escaped. Another 25 c.c. of alcohol is then added through the measuring tube and the level of the meniscus read. A value for the apparent specific gravity is thus obtained, from which the proportion of incombustible dust may be estimated by reference to calibration curves of synthetic mixtures.

—C. A. K.

Coals; Weights of various — S. B. Flagg. U.S. Bureau of Mines, Tech. Paper 181, 1918. 13 pages.

THE TESTING of many kinds of American coals for Government purposes has afforded the opportunity of observing the relative weights of different varieties from the point of view of storage. General conclusions only are justified, as many factors are involved. Slack coal composed of a mixture of small pieces up to nut size is denser than screened nut coal, as the voids are more com-

pletely filled. Coal with a high moisture content is usually lighter than a similar sample with less moisture. Higher densities are to be expected for coals of high fixed carbon content, and the reverse applies to coals with a large percentage of ash; younger coals, in general, are lighter than those of earlier formation.—C. A. K.

Coal; Determination of ash of — H. Mastbaum. Chem.-Zeit., 1918, 42, 385—386, 391—392.

INCINERATION in a muffle-furnace does not always give the same result in the determination of the ash of coal as is obtained when the sample is ignited over a Bunsen burner; the latter method always gives a higher result when the coal contains much calcium carbonate, since this is not decomposed completely and at the same time sulphur compounds are absorbed from the products of combustion of the gas. If a muffle-furnace is not available, the coal should be ignited over a spirit flame or in an electric furnace. For commercial purposes, it is desirable that the method of determining the ash of coal and the temperature employed should be prescribed.—W. P. S.

Bituminous coal; Storage of — J. H. Anderson. Trans. Inst. of Marine Eng., 1918, 30, 81—98.

AN account is given of the measures adopted to avoid spontaneous combustion of stacked coal with special reference to a pile, in the open, of 16,000 tons of mixed coals—Scotch, North of England, and Yorkshire. The maximum depth of the pile was 16 ft. Vent pipes were inserted at various points. They were 3 in. in diameter and 8 ft. long, with perforations in the side, and the lower end hammered, chisel-shape, so as to leave an aperture of $\frac{1}{2}$ in. Smaller tubes of 1 in. piping, reaching to the bottom, were inserted over the area of the stack to permit of temperature measurements, which were recorded systematically every day. The temperature was taken at a depth of 7 ft., which was the warmest stratum. Action was taken as soon as a temperature of 90° F. (32° C.) was recorded. Other temperature-measuring tubes were then driven in at points round about until the source of the heating was located. When found, a vent pipe was inserted and the rise of temperature was thereby arrested. If, however, a temperature of 100° F. (38° C.) was found, the stack was trenched above the spot to a depth of 1 ft. and this was repeated daily until the rise of temperature was arrested. The author recommends as maximum depths 12—14 ft* for small graded coal, 9—12 ft. for unwashed mixed coal. He has found stacks to heat when stacked only 6 ft. deep.—H. J. H.

Coal; Absorption of methane and other gases by — S. H. Katz. U.S. Bureau of Mines, Tech. Paper 147, 1917. 22 pages.

SAMPLES of air-dried Pittsburgh bituminous coal (moisture 1.61%, volatile matter 37.67%, fixed carbon 55.38%, ash 5.34%) were pulverised to pass a 200-mesh sieve and exposed in closed vessels to atmospheres of air or nitrogen containing known quantities of methane. Computations were made from pressure changes and from gas analyses made with a Haldane apparatus. In the air-methane atmosphere containing 3% methane, an equilibrium was established between the methane and the coal in about four hours, but oxygen was continuously absorbed by the coal and minute quantities of carbon dioxide and monoxide were formed. Freshly pulverised coal, which already contained some methane, absorbed 0.08 c.c. per gm., but coal which had previously been exposed to the

atmosphere for five weeks and had consequently lost some methane absorbed 0.16 c.c. per gm. In the nitrogen-methane mixtures the coal (after five weeks' exposure to the atmosphere) was first introduced into a pure nitrogen atmosphere and left until the absorption of nitrogen ceased and the pressure remained constant. A percentage of methane was then added and comparatively rapid absorption occurred at first, but after two hours an evolution commenced and continued for seven days, after which the pressure (compensated for ordinary expansion) in the closed vessel rose and fell with the temperature. The volume of methane absorbed increased with increase in the partial pressure of the methane, and nitrogen was simultaneously evolved, in amounts somewhat less than the volume of methane absorbed. For methane and nitrogen a definite equilibrium exists, for each temperature, between the partial pressures of the gases and the quantity absorbed by the coal. So far as investigated, the absorption of gases by Pittsburgh coal is closely analogous to the absorption of gases by charcoal.—T. F. E. R.

Coke; Formation of — G. Charpy and M. Godchot. *Comptes rend.*, 1918, 167, 322–324.

Non-caking coals containing a low percentage of volatile matter can be made to yield a satisfactory coke when they are mixed with a suitable proportion of coal containing an excess of volatile matter which would yield a very bulky and friable coke. Thus a Brassac coal containing 11% of volatile matter when mixed with a Durham coal containing 24% of volatile matter gave the following results by coking at 700° C. For mixtures containing 25% of Durham coal the coke had a resistance of 24 kilos. per sq. cm.; containing 44% a resistance of 45 kilos.; and containing 51% a resistance of 80 kilos. per sq. cm.; above this content the resistance rapidly fell to zero. The content of volatile matter in a mixture giving a coke with the maximum resistance was found to vary considerably with the different coals used. The coking properties of a coal poor in volatile matter may also be improved by addition of the requisite amount of pitch or tar coming from a previous distillation. In the case of a coal too rich in volatile matter, if the latter be suitably reduced by a partial distillation at 450° C., a satisfactory coke can then be obtained by coking at 700° C.—W. G.

Coking of Illinois coals. F. K. Oritz. U.S. Bureau of Mines, Bull. 138, 1917. 71 pages.

The first part of the report deals with the quality and the possible uses of the coke produced from Illinois coal, alone, or when mixed with other coals low in volatile matter. The value of the coals for the production of gas and by-products and the effect of impurities in the coal, on the coke and gas made, are discussed. The second part deals with the nature, physical properties, and chemical composition of Illinois coals and special reference is made to the non-homogeneous structure of the coal. The last part describes in detail the large-scale tests made in beehive ovens, by-product ovens, and gas retorts respectively. Coke from Illinois coals is usually light and friable and contains a large amount of non-fused material, e.g., shale, etc. Mixing with Eastern coal of low volatile content to the extent of 20% Illinois coal produced coke of improved quality. High carbonising temperature appears to improve the coke but the results are not conclusive. Addition of 5% of pitch improves the coke. The yield of gas in by-product ovens ranged from 11,000 to 13,000 cub. ft. per ton (2000 lb.). The average yield of ammonia in by-product ovens was 26.6 lb. of sulphate and in gas retorts about 23 lb.; while the

average tar was 11.9 galls. per ton in the former and about 10–12 galls. in the latter method of carbonisation. Owing to the high sulphur and ash content of Illinois coals their use for coking is limited, and mixing with low sulphur coals is generally necessary. Washing is also usually necessary, and about 25% of the sulphur and 20–30% of the ash are removed during the process. The cost of washing is 5 to 10 cents per ton and from 10 to 25% of the coal is lost during the operation. Crushing the coals before using produced better coke, because the non-fusible layers of the coal were broken up and cemented together by the fusible portions of the coals. Illinois coals contain 37.5 to 46.5% volatile matter; sulphur 1.42 to 5.55%; ash about 10%; oxygen about 11% (all on the dry basis) and low phosphorus. About 40% of the volatile matter (14% of the coal) is "inert" and is driven off largely as water of decomposition, carbon dioxide, and nitrogen. The paper contains eleven plates illustrating the nature of the coke from Illinois coal and its mixtures with other coals, and a selected bibliography.—T. F. E. R.

[*Heat*.] *Apparatus for measuring the loss [of —] up the chimney and the elements constituting this loss.* M. Chopin. *Comptes rend.*, 1918, 167, 335–338.

The apparatus consists essentially of a pyrometer and an ammeter so arranged that their pointers cross between their scales. In the area where these points of intersection occur are plotted curves from which the percentage loss up the chimney may be read off. The pyrometer registers the temperature of the gases at the base of the chimney, and the ammeter registers the carbon dioxide content of the flue gases, being controlled by the electrical resistance of a solution of sodium hydroxide before and after a known volume of the gases has been bubbled through it.—W. G.

Flames; Propagation of — through tubes of small diameter. W. Payman and R. V. Wheeler. *Chem. Soc. Trans.*, 1918, 113, 656–666.

When an inflammable mixture of methane and air, contained in a tube closed at one end, is ignited near the open end of the tube, the flame is found to travel with uniform speed towards the closed end of the tube. The speed of the uniform movement diminishes as the diameter of the tube is reduced as a result of the loss of heat by conduction through the walls of the tube. Further reduction prevents the development of the "uniform movement," and when the diameter is sufficiently small, the flame is not able to spread any measurable distance from the point of ignition. Experiments made with gas mixtures containing from 7.6 to 12.0% methane and tubes varying in internal diameter from 3.6 to 9.0 mm. showed that the range of gas mixtures, in which the uniform movement is developed, becomes smaller as the diameter of the tube is decreased, until with a tube of 4.5 mm. diameter, only one of the mixtures tested (9.95% methane) was found to propagate the flame. The speed with which the flame is propagated tends towards a constant value of about 35 cm. per second as the limiting mixtures are approached. This speed is considered to represent the smallest speed at which continued propagation of flame is possible in mixtures of methane and air. When mixtures of methane and air, contained in horizontal tubes open at both ends, are ignited near one end of the tube, flame begins to travel with increasing speed towards the other end. When a certain distance has been traversed, the flame vibrates backwards and forwards and in tubes of small diameter such vibration leads to the extinction of the flame. The

distance travelled before vibrations begin increases with the length and the diameter of the tube and decreases as the percentage of methane in the mixture approaches that corresponding with the maximum speed of propagation. The relations between these quantities are such that a length of tube of diameter small enough to prevent the passage of flame in a mixture containing say 10% of methane may fail to do so when the mixture contains only 7% of methane, although the former mixture has a greater speed of propagation. In an attempt to realise approximately the conditions under which an inflammation of firedamp takes place within a miner's safety lamp, experiments were also made to determine the length of brass tube which is required to prevent the passage of flame when a 10% methane-air mixture is exploded. The mixture was contained in tubes 2 cm. in diameter and was ignited at the closed ends of these tubes. By varying the lengths of these explosion tubes it was possible to vary the speed acquired by the flame by the time it reached the brass exit tube. Results obtained with brass tubes of 4 to 8 mm. diameter showed that the increased speed of the flame which is obtained by the use of a long explosion tube, reduces materially the protection against inflammation of the external atmosphere which is afforded by brass tubes. An increase in the diameter of the explosion tubes was found to be without influence on the transmission of inflammation. (See also *J. Chem. Soc.*, Oct., 1918.)—H. M. D.

Water determination in mineral oils; Modification of benzol method of —. F. C. Fuchs. *Eng. and Min. J.*, 1918, 106, 357.

In the determination of water by distillation with a non-miscible liquid (e.g., benzene), drops of water may remain, in suspension in the benzene, on the walls of the measuring burette and are not easily detected. The addition of a colouring substance soluble in benzene but not in water (e.g., natural asphalt) shows the colourless drops distinctly in the coloured benzene, and by gentle tapping the drops are made to descend into the aqueous layer.—C. PATENTS.

Fuel from waste materials and making and utilising the same. J. E. Hughes, Liverpool. *Eng. Pat.* 117,921. (Appl. Nos. 9701, July 5, and 15,495, Oct. 23, 1917.)

GROUND anthracite, shale, with or without slack, peat, spent tan, or other vegetable refuse, is mixed with a binder such as waste from the manufacture of caustic soda, scum from beet sugar manufacture, or other chemical waste consisting largely of calcium carbonate. The mixture is pressed into pellets which may be burned in a forced draught with or without steam. The pellets may be used for household fires with occasional rekindling with a blow lamp, or larger pieces may be used for furnaces or for generating power gas on motor vehicles.—W. F. F.

Fuel briquette. W. Kennett and E. T. Krebs, Carson City, Nev. U.S. Pat. 1,273,619, July 23, 1918. Date of appl., Feb. 13, 1918.

A FUEL briquette consists of crushed oil shale and a heavy semi-liquid binder of carbonaceous matter containing a resinous material in solution.

—W. F. F.

Furnaces [; Gas —]. A. C. Ionides, jun., London. *Eng. Pat.* 117,923, July 9, 1917. (Appl. No. 9893 of 1917.)

BACK firing of a mixture of air and gas is prevented by forming a cavity or depression in the furnace wall immediately opposite to the burner nozzle, so as to maintain a stratum of more or less stagnant and consequently cooler gas between the burning jet and the wall opposite thereto.—W. H. C.

Burner for gas-fired furnaces. H. J. Yates, Birmingham, S. N. and E. R. Brayshaw, Manchester. *Eng. Pat.* 118,239, Oct. 16, 1917. (Appl. No. 4812 of 1918.)

THE burner comprises a tubular casing open at one end and provided with a gas nozzle of T-shape projecting into it, the horizontal arm of the T being co-axial with the casing and open at both ends. The orifice nearest the open end of the casing is of larger diameter than the other. An air nozzle is fixed some distance behind the gas nozzle and co-axial with it, so that the greater part of the air passes around the gas nozzle, and a portion passes through it and mixes with the gas. The mixed gases are ignited on issuing from the casing.

—W. F. F.

Producer gas; Method of making —. J. W. Hornsey, Summit, N.J., Assignor to General Reduction Gas and By-Products Co. U.S. Pat. 1,270,949, July 2, 1918. Date of appl., Oct. 9, 1911. Renewed Nov. 24, 1917.

CARBONACEOUS material and an oxidising agent are fed continuously through a heated horizontal rotating vessel. The material is retarded in its longitudinal travel by transverse radial ribs on the wall of the vessel, and is lifted and allowed to fall by longitudinal ribs between the transverse ribs. The ribs of adjacent series are not in longitudinal alignment, so that a more intimate mixing with the oxidising agent is obtained.—W. F. F.

Gas-producer. A. M. Gow, Duluth, Minn. U.S. Pat. 1,272,252, July 9, 1918. Date of appl., Dec. 20, 1917.

THE fuel in the coking zone of a gas-producer is maintained in a porous condition by the vertical reciprocation of a transverse chopper. The chopper is hollow and carried by a hollow vertical shaft through which a cooling medium circulates, and the shaft is reciprocated vertically by means of a piston working in a cylinder and operated by fluid pressure. The fluid pressure also operates a pawl and ratchet, so that after each stroke the chopper is partly rotated about its vertical axis when raised above the fuel bed.—W. F. F.

Gas-producers; Charging and poking mechanism for —. M. J. Owens, Assignor to The Toledo Glass Co., Toledo, Ohio. U.S. Pat. 1,273,177, July 23, 1918. Date of appl., Nov. 5, 1914.

A GAS-PRODUCER is provided with a cover plate movable horizontally and provided on one half with a number of pockets to distribute coal uniformly over the grate. The other half of the cover plate carries a series of vertical guide tubes containing

pokers which are mounted on a common crosshead and reciprocated by fluid pressure. The cover may be moved so that either half is over the producer. Each coal pocket is provided with slides at top and bottom, and a complementary series of supply shoots is arranged at the side of the producer to supply the pockets when the cover is displaced so that the pokers are over the grate.—W. F. F.

Gaseous mixtures; Separation of the constituents of — [e.g., methane from natural gas]. B. S. Lacy, Seward, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,272,059, July 9, 1918. Date of appl., Sep. 20, 1916.

To separate methane from natural gas, the compressed gas is passed through one channel of a temperature exchanger, when it is expanded and the liquefied hydrocarbons are separated. The non-liquefied gas is passed through a second channel of the exchanger in an opposite direction to the first. The liquefied hydrocarbons are evaporated at a rising temperature by passing them through the lower part of a third channel of the exchanger also in an opposite direction to the first, the gas produced passing on through the upper part of the channel.—J. H. J.

Gas; [Electrolytic] process of making combustible — C. F. Euler, Topeka, Kans. U.S. Pat. 1,273,050, July 16, 1918. Date of appl., Apr. 4, 1916.

An electric current is passed through water containing insufficient acid or salt to liberate any substantial amount of gas other than oxygen and hydrogen. The anode and cathode are horizontal, the cathode being below the anode, so that the gas liberated from the cathode rises past the anode and mixes intimately with the gas liberated uniformly from it. The gases are withdrawn from the closed container without admixture of extraneous gases.—W. F. F.

Coal gas retorts and generator plants; Operation of — H. Strache, Vienna. Ger. Pat. 305,721, Sep. 28, 1916. Under Int. Conv., Sept. 30, 1915.

The producer is operated with bituminous coal, and the mixture of producer gas and coal gas produced during the period of blowing with dry air is utilised for heating coal gas retorts. As soon as the temperature in the lower part of the producer is sufficiently high, the current of air is replaced by steam and the water gas, which is also enriched with coal gas on passing through the layer of coal in the upper part of the producer, is led off through another outlet and mixed with coal gas from the gas retorts.—L. A. C.

Moist fuel; Drying of and gas production from — A. Eckardt, Zwickau. Ger. Pat. 306,060, Mar. 4, 1916. Addition to Ger. Pat. 302,827 (this J., 1918, 330 A).

The furnace used for drying the fuel is utilised also for heating the mixture of steam and air delivered beneath the grate of the producer.—L. A. C.

Gases obtained from coal or other carbonaceous fuel; Recovery of cyanogen bearing compounds from — B. V. Espenbain, Brighton, Victoria, Australia. Eng. Pat. 109,254, July 25, 1917. (Appl. No. 10,703 of 1917.) Under Int. Conv., Aug. 8, 1916.

The gas to be purified is passed through centrifugal or other washers to remove tar, and then through a strong solution of sodium carbonate containing

ferrous sulphide in suspension at a temperature of 40°–90° C. Sodium ferrocyanide is produced by the action of hydrogen cyanide gas, the sludge is removed by filter-pressing, and the salt crystallises on cooling. The clear liquid is returned to the washing tank with the addition of fresh sodium carbonate and ferrous sulphide. The sodium ferrocyanide may be treated with sulphuric acid to produce hydrogen cyanide, which is subsequently converted into alkali cyanides and sodium ferrous ferrocyanide. The latter may be used with sodium carbonate for the washing tank, when sodium ferrocyanide and ferrous sulphide are produced by the action of hydrogen sulphide. The ferrous sulphide then reacts with sodium carbonate and hydrogen cyanide as described above. In a modification, the gas may be first treated for the recovery of ammonia and a portion of the gas may be passed through a solution of ferrous sulphate to produce ammonium sulphate free from cyanides by the action of ammonia and hydrogen sulphide. Ferrous sulphide is also formed and may be mixed with sodium carbonate for washing the gas as above. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 10,876 and 26,566 of 1902 and 2929 of 1906; this J., 1903, 691, 1243; 1906, 536.)—W. F. F.

Petrol; Manufacture of volatile oils such as — M. A. H. de Dampierre, Paris. Eng. Pat. 109,796, Aug. 15, 1917. (Appl. No. 11,745 of 1917.) Under Int. Conv., Sep. 6, 1916.

HYDROGEN is injected into heavy oil whilst this is being heated in a still, and the mixed vapours and gas ascend through a water-cooled vertical pipe containing a number of perforated nickel discs. A safety valve situated at the upper end of the pipe allows a determined pressure to be maintained in the still and pipe. The vapours of the heavy oil condense and run back into the still, whilst the hydrogen and the vapours of volatile oils pass through the valve to a condenser.—T. St.

Liquid fuel [for internal combustion engines]. S. Dyson, Elland, Yorks. Eng. Pat. 118,021, Sep. 12, 1917. (Appl. No. 16,272 of 1917.)

MINERAL oil, including olefines, paraffins, or other hydrocarbons not of coal tar origin, 70 parts, and carbon bisulphide, 30 parts, are mixed with slaked lime 5–10 parts, and the mixture agitated and then washed with water which is drained off with the impurities.—W. F. F.

Hydrocarbon oils; Process of refining — H. T. Maitland, Marcus Hook, Pa., Assignor to Sun Co., Philadelphia, Pa. U.S. Pat. 1,272,979, July 16, 1918. Date of appl., Jan. 13, 1916.

A STREAM of sulphuric acid is broken up into an extremely finely divided state by a stream of gas, and the resulting mist discharged into an inverted funnel, the open end of which dips below the surface of the oil. The body of oil is independently agitated to ensure thorough distribution of the acid particles which are forced below its surface by the pressure exerted by the stream of gas.—T. St.

Still for crude bituminous materials. C. P. Price, Assignor to American Tar Co., Malden, Mass. U.S. Pat. 1,273,091, July 16, 1918. Date of appl., Dec. 3, 1912.

The still is provided with a trough at its upper edge, and a conical cover seating in the trough. The distillate runs down the cover into the trough and is withdrawn at a number of points by right-angled branch pipes into a common collecting pipe.

The short vertical section of each branch pipe leading into the collecting pipe carries a funnel at its upper end. The still is heated by a pipe coil through which steam is passed.—W. F. F.

Producer-gas; Process of manufacturing —. E. Fleischer, Dresden-Alstadt, Germany. U.S. Pat. 1,273,474, July 23, 1918. Date of appl. May 13, 1914.

SEE Fr. Pat. 471,341 of 1914; this J., 1915, 414.

[Mineral] oils; Process and apparatus for purifying —. E. C. R. Marks, London. From The Swan Process Oil Co., Deventer, Colo., U.S.A. Eng. Pat. 118,353, Sep. 25, 1917. (Appl. No. 13,784 of 1917.)

SEE U.S. Pat. 1,250,526 and 1,250,527 of 1917; this J., 1918, 117A.

Art of separating materials from gases. U.S. Pat. 1,273,791. See I.

Process and means for producing oils for different purposes from sharp, middle, cresotic, or similar oils. Eng. Pat. 117,914. See III.

II.B.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Carbonaceous substances; Apparatus for the destructive distillation of —. S. N. Wellington, London. Eng. Pat. 117,929, July 30, 1917. (Appl. No. 10,974 of 1917.)

A SAFETY device for insertion in a gas main comprises a pressure chamber fitted with one or more mushroom valves. Each valve rod is connected to the valve of a whistle operated by compressed air, so that the whistle is blown when the pressure in the main becomes excessive.—W. F. F.

Shale or the like; Apparatus for the treatment [distillation] of —. R. M. Catlin, Franklin, N.J., Assignor to Catlin Shale Products Co., Wilmington, Del. U.S. Pat. 1,272,377, July 16, 1918. Date of appl., Aug. 9, 1917.

AN inclined tubular retort for the distillation of shale or the like is provided with a concentric helical conveyor of diameter slightly less than the retort and of varying pitch. The material is fed forward more quickly and is thus spread out more thinly as it approaches the outlet end.—W. F. F.

Gas lighting. Gaseous combustion. A. C. Ionides, jun., London. Eng. Pat. 118,313. (Appl. Nos. 11,891, Aug. 18, and 16,806, Nov. 15, 1917.)

Gas supplied by a blower passes through a governor, which maintains the pressure between predetermined limits, to a double beat valve and thence to one side of a floating bell. Air is supplied by another blower at a higher pressure to another double beat valve and thence to the other side of the floating bell. The bell actuates the two valves so as to maintain the relative pressures of gas and air at any desired ratio. The gas and air pass by separate pipes to any system of burners, each burner being adjusted to pass the correct proportions of gas and air at the given pressure ratio. Temporary variations in the quality of gas are compensated by adjusting a cut-off valve on the air supply pipe. When any

permanent adjustment of all the burners is required a test light or test flame is adjusted at the same time, so that if there is a temporary variation in the quality of the gas the necessary adjustment of the air valve may be made with reference to the test light.—W. F. F.

Incandescence mantles; Collodion coating for —. R. Langhans, Berlin. Ger. Pat. 306,103, Nov. 21, 1917.

COLLODION to be used as a protective coating for burnt-off incandescence mantles, is mixed with a molecular compound of phthalic anhydride with an aromatic amino or hydroxy compound.

—J. F. B.

Incandescence lamps; Manufacture of [electric] —. F. Blau, Charlottenburg, Germany, Assignor to General Electric Co. U.S. Pat. 1,269,520, June 11, 1918. Date of appl., Apr. 18, 1916.

BARIUM azoimide is introduced into the bulb of an incandescence lamp and decomposed by heating to a temperature below the softening point of the glass, so as to produce metallic barium and anhydrous barium oxide on the internal surface of the bulb, the barium oxide acting as a drying material.—B. N.

Electrode for arc-lamps. H. R. Edgecomb, St. Marys, Pa., Assignor to Speer Carbon Co. U.S. Pat. 1,272,401, July 16, 1918. Date of appl., Dec. 7, 1916.

THE electrode comprises an inner core, and an outer shell of carbon capable of burning at approximately the same rate as the core, the shell being coated with a material of greater electrical conductivity. An electrically-conducting heat-insulating film containing carbon is disposed between the core and the shell.—B. N.

Film conductor [for electrical discharge apparatus] and the method of making the same. I. Langmuir, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,273,628, July 23, 1918. Date of appl., June 6, 1914. Renewed May 1, 1917.

GAS-FREE adherent metallic conducting films, for use as anodes in electrical discharge apparatus, are deposited upon insulating surfaces, by heating a highly refractory metal to a temperature near its melting point in a vacuum having a residual gas pressure below 0.001 mm. of mercury, i.e., too high to permit of the passage of a disruptive discharge, the surface upon which the film is to be deposited being exposed to the metallic vapour. —B. N.

Incandescence lamps; Method of exhausting —. I. Langmuir, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,273,629, July 23, 1918. Date of appl., Dec. 5, 1914.

SEE Eng. Pat. 1088 of 1915; this J., 1916, 105.

[Electric lamps;] Leading-in conductor [for —]. C. G. Fink and W. E. Koerner, East Orange, N.J., Assignors to General Electric Co. U.S. Pat. 1,273,758, July 23, 1918. Date of appl., Sep. 25, 1915.

III.—TAR AND TAR PRODUCTS.

Tar oil in Diesel engines. H. Moore. Diesel Engine Users' Assoc., May 26, 1918. [Reprint.] 24 pages.

Almost all heavy tar distillates are suitable for use in Diesel engines. The gross heat value of tar oils of British origin averages 10·2% less than that of the petroleum oils sold in this country, but the increase in consumption is not higher by this amount for the reasons that tar oil generally yields a higher thermal efficiency than petroleum oil (probably due to its lower viscosity), and owing to the average hydrogen content of tar oil being only about 6·9% as against about 11·5% for petroleum oils, the difference between gross and net calorific values is not so great as with petroleum oils. The average ignition point of tar oils is about 480° C. as against 260° C. for petroleum oils, and it is this difference which is responsible for the troubles in obtaining ignition of tar oils. With a normal tar oil, petroleum is necessary for starting with compressions below 670 lb. per sq. in., but good running is obtained at over $\frac{3}{4}$ load with a compression of 460 lb. per sq. in. Shale oil is particularly serviceable as an ignition oil with pilot ignition gear on account of its low ignition point. High temperatures of the circulating water help the combustion of tar oil to a small extent. Heating the cycle air lessens output of the engine by rarefying the air, but aids the combustion of tar oils. Advancing the fuel valve is a distinct advantage. The best results have been obtained with 9° advance when burning tar oil alone, and about 5° advance when using pilot ignition gear (running engine at 250 revs.). Mixing oils is of doubtful advantage, as it is necessary to employ more than half petroleum to obtain moderately good results, even when oils are such as will stand mixing without forming deposits. Hot blast is by far the most helpful modification for burning tar oil, but is rather dangerous, as it might cause explosions in the fuel valve casing. The fuel valve face suffers a little more with hot blast than in normal practice. Heating the fuel is useful from the point of view of increasing efficiency by reducing viscosity and as a means of dissolving naphthalene. Improved running on tar oil at low loads is obtainable by restricting the flame plate, but this is only at the expense of the full load results. Wear on exhaust valve is not very serious with tar oils, but is a much more important matter when burning raw tars. It only becomes serious when firing is uncertain, and is generally much worse when running on tar oil alone than with the pilot ignition system. Oils which give an abrasive ash on ignition may cause trouble even when this amounts to less than 0·08%, but when the ash consists largely of sodium sulphate (arising from washing tar acids from creosote), much higher ash contents are permissible. Tar oils containing pitch cause many troubles, but it is almost entirely the free carbon which affects the use of such mixtures in internal combustion engines.—T. St.

PATENTS.

Sharp, middle, creosote or similar oils; Processes and means for producing oils for different purposes from —. A. F. Martin, London, Eng. Pat. 117,914, June 7, 1917. (Appl. No. 8319 of 1917.)

The oil is mixed with aqueous sodium hydroxide solution, agitated and heated, and the mixture allowed to settle. The liquid portion is run off into a still and distilled for fractions boiling respectively below 180° C., from 180° to 225° C., and from 225° to 360° C. The first fraction is mixed with an equal amount of benzol or petrol, and the mixture redistilled. The fraction distilling between

90° and 180° C. is a high-grade motor fuel, having a flash point of 35°—45° F. (about 2°—7° C.), or over, and sp. gr. approximately 0·7—0·75. By again distilling the latter fraction from 90° to 180° C., a high-grade aeroplane motor spirit oil is produced. The second main fraction is suitable, either without further treatment, or, if dark in colour, after redistilling, for use as a Diesel engine oil. The third main fraction is gently heated and agitated with an addition of a quantity of finely disintegrated commercial pitch, whereby a good boiler fuel oil is obtained. A combination of apparatus, and devices for economically carrying out the several steps of the process, are described. —T. St.

Aniline-reducer. A. H. Stevens, Brooklyn, N.Y., Assignor to Stevens Bros., New York. U.S. Pat. 1,267,819, May 28, 1918. Date of appl., Mar. 25, 1918.

AN apparatus for the production of aniline by reduction of nitrobenzene with iron filings and hydrochloric acid comprises a tank provided with a false bottom and a removable lining to allow of easy renewal after corrosion. A horizontal bar passes through a slot in the lower end of a vertical shaft mounted within the tank and this bar carries rabble blades which are mounted on the bar in such a way that the latter is practically completely enclosed and thus largely protected from corrosion.

Aromatic hydrocarbons; Process of producing —. R. L. Hill, Chester, Pa., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,269,439, June 11, 1918. Date of appl., July 26, 1915. Renewed Mar. 28, 1918.

AROMATIC hydrocarbons of higher boiling point than toluol (e.g., heavy naphtha) are heated with an alkaline-earth carbide, such as calcium carbide, at a temperature exceeding 500° C., and under a pressure greater than atmospheric pressure. Hydrocarbons of lower boiling point are produced. —C. A. K.

Still for crude bituminous materials. U.S. Pat. 1,273,091. See IIA.

Manufacture of impregnated material. U.S. Pat. 1,273,673. See XIII.

IV.—COLOURING MATTERS AND DYES.

Dyestuffs; Natural —. Bull. Imp. Inst., 1918, 16, 1—16.

Brazilletto wood from the Bahamas. This dyewood is derived from a species of *Casalpinia*. Three samples were received in pieces 16—38 ins. long and $1\frac{1}{2}$ —3 ins. thick. They all yielded colours similar to those obtained with commercial Brazil wood, the only difference being in the depth of colour obtained on wool mordanted with alum. The aqueous extract ranged from 8 to 11%. These Brazilletto woods were quite different from a sample of "Brazilada" wood previously received from the Bahamas, which resembled logwood in appearance and properties. They are not likely to be of much commercial interest. A sample of logwood from the Bahamas was judged to be of good quality equal to the best Jamaica wood.

Indigo from Nyasaland and Nigeria. Two samples from Nyasaland contained respectively 20·4 and 36·1% of indigotin, the former showing 22·2% of ash, principally earthy matter. They were classed commercially as "low" and "middling," and had been prepared from wild plants. A sample from

Nigeria showed 31·3% of ash, 27·5 of indigotin, and 1·5 of indirubin (Indigo Red); it was classed as rather low grade, but marketable.

"Indian madder" from S. Africa. A sample of roots of *Rubia cordifolia* from Natal was considered to be equal in quality to the Indian product and stronger than commercial ground madder (*R. tinctorum*); the tints obtained with the Natal roots differed somewhat from those given by the standard samples of madder.

Lichen from the Falkland Islands. A sample of bushy lichen, very abundant in the Falkland Islands, was identified as *Neuropogon melananthum*, giving buff, orange, and brown shades on boiling with unmordanted wool. Prolonged boiling gave darker colours, especially with the addition of ammonia. This lichen possesses dyeing properties which make it suitable for local use, but it would be of no interest for export.—J. F. B.

Colouring matter of the glumes of the sweet Sorghum; Industrial application of the —. A. Piédallu. Comptes rend., 1918, 167, 345—348.

The glumes of the sweet Sorghum and of several varieties of Sorghum with black glumes contain a dye, which can be extracted with dilute acid and which dyes wool, silk, leather, and cotton. The dye is extracted by heating the glumes in an autoclave with 1% sulphuric or hydrochloric acid or with 2% sodium bisulphite. The colours obtained on wool and silk are bright and strong, the shades being from violet to red, from beige (natural wool colour) to brown, and from pearl grey to deep grey varying with the mordant. The dye may be used with or without mordants, the most satisfactory mordant being stannous chloride, which gives bright amaranth and crimson tints. All the shades are fast to washing. They pass a little towards violet under the influence of alkali, the tint being restored by dilute acid.—W. G.

p-Phenylenemethyldiamines; Acylated —. G. T. Morgan and W. R. Grist. Chem. Soc. Trans., 1918, 113, 688—694.

METHYLANILINE is prepared by treating aniline with formaldehyde in presence of zinc dust and caustic soda (Eng. Pat. 102,834; this J., 1917, 207) and the secondary base is converted into acyl derivatives by heating for several hours with concentrated formic acid, acetic acid, etc. The corresponding *p*-phenylenemethyldiamine derivatives may be obtained by known methods, the most convenient being by nitration of the acylmethyl-aniline and reduction of the *p*-nitro compound, which is the main product of the nitration with ordinary nitrating mixture at 0°—10° C. *p*-Aminomethylformanilide, m.p. 132° C., and *p*-aminomethylacetanilide, m.p. 63° C., when treated with nitrous anhydride in dry acetone solution, give colourless diazonium hydroxides which combine with dry β -naphthol with elimination of water. Azo dyestuffs are formed by diazotising the *p*-aminomethylacylanilides in the ordinary way and coupling with various phenolic compounds. (See also Eng. Pat. 111,321; this J., 1918, 5A.)—J. F. B.

Benzanthrone; A new synthesis of —. II. Transformation of 1-phenylnaphthalene-2,3-dicarboxylic acid anhydride into benzanthronecarboxylic acid. A. Schaarschmidt and E. Korten. Ber., 1918, 51, 1074—1082.

WHEN 1-phenylnaphthalene-2,3-dicarboxylic acid anhydride (I) is heated with 91% sulphuric acid for 3 hours at 155° C., it yields benzanthronecarboxylic acid (III) and a sulphonated 3,4-benzofluorenone-1-carboxylic acid (II). As this acid (II)

is the product formed by the prolonged action of sulphuric acid in the cold, and gives the same result if heated as above, the chief reaction may be represented thus:

It is an example, therefore, of the rupture of a weak 5-ring and establishment of a 6-ring. 3,4-Benzofluorenone itself suffers a similar change when heated with sulphuric acid, and the imide corresponding with the above anhydride exhibits the phenomenon most readily. (See further J. Chem. Soc., 1918, 1, 434.)—J. C. W.

Benzanthrone; A new synthesis of —. III. A. Schaarschmidt and E. Georgacopol. Ber., 1918, 51, 1082—1087.

WHEN 3,4-benzofluorenone is fused with potassium hydroxide, the 5-ring is ruptured in the two possible ways, the products being salts of 1-phenylnaphthalene-2-carboxylic and *o*- α -naphthylbenzoic acids. If the free acids are treated with phosphorus pentachloride and then aluminium chloride, the former yields 3,4-benzofluorenone again and the latter benzanthrone. (See further J. Chem. Soc., 1918, 1, 434.)—J. C. W.

Quinonoid dyes; Nature of cyclic —. F. Kehrman. Annalen, 1917, 414, 131—188.

A THEORETICAL paper containing a discussion of the results of investigations of the constitution of azonium, azthlonium, azoxonium, carboxonium, carbothonium, and acridonium compounds. They are regarded in general as desmotropic substances which acquire the ortho- or the para quinonoid structure according to the conditions. (See also J. Chem. Soc., 1918, 1, 449.)—C. S.

PATENTS.

Lignine sulphonic acid or its salts; Method of preparing azo colouring matters from —. E. Oman, Stockholm. Eng. Pat. 103,822, Jan. 4, 1917. (Appl. No. 201 of 1917.) Under Int. Conv., Jan. 28, 1916. Addition to Eng. Pat. 103,479.

AFTER the coupling has been made according to the process specified in Eng. Pat. 103,479 (this J., 1918, 407A), an inorganic or organic base is added, with stirring, to the reaction mixture until slightly alkaline, whereby the corresponding salt of the azo compound is precipitated, or may be precipitated by means of a salt, e.g., a soluble carbonate. If the reaction be carefully carried out at a low temperature, the base may be added to the diazotised amine before coupling. The colour of the precipitated compound varies according to the base employed.—J. F. B.

Mono-azo dyestuffs of the pyrazolone series able to be chromated and process of making same. E. Reber, Assignor to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,270,325, June 25, 1918. Date of appl., Sep. 11, 1917.

NEW mono-azo dyes of the pyrazolone series are prepared by combining diazo-derivatives of anthranilic compounds with hydroxyaryl substituted

pyrazolones. In particular, the dyestuff obtained by coupling the diazo-derivative of anthranilic acid with 1-(5'-sulpho-3'-carboxy-2'-hydroxy)-phenyl-3-methyl-5-pyrazolone dyes wool yellow tints in an acid bath which turn to brownish-yellow on being after-chromed.—L. A. C.

Vegetable dye and process of making same. H. Warkup, Kingston, N.Y., Assignor to J. S. Young and Co., Hanover, Pa. U.S. Pat. 1,273,293, July 23, 1918. Date of appl., Dec. 20, 1917.

A QUERCITRON extract is evaporated to form a thick liquid, which is then treated at the boiling point with a number of mordanting substances. After standing for some time, the liquid is neutralised or rendered slightly alkaline with sodium carbonate, heated to expel carbon dioxide and finally evaporated *in vacuo* to about 51° Tw. (sp. gr. 1.255). The bath produced by dilution of the product can be used for the direct mordanting and dyeing of cotton.—L. A. C.

Ortho[hydr]oryazo dyestuffs; Substantive — and a process of making same. E. Anderwert, H. Fritzsche, and H. Schobel, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pats. 1,265,030 and 1,265,031, May 7, 1918. Date of appl., Jan. 24, 1917.

SEE Eng. Pat. 12,250 of 1915; this J., 1916, 1008.

Gallocyanine dyestuffs; Condensation product of — with amines, and process of making same. A. Grob and J. Würzler, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,268,453, June 4, 1918. Date of appl., July 7, 1917.

SEE Eng. Pat. 116,754 of 1917; this J., 1918, 407A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Silks; Differentiation of natural and artificial —. A. Herzog. *Kunststoffe*, 1917, 7, 277—278. *Z. angew. Chem.*, 1918, 31, Ref., 225.

A PHYSICAL method of differentiation is described which is based on the differences between the refractive indices and which is applicable in the case of dyed fibres. A fibre of natural silk mounted in aniline and examined under a microscope with a Nicol prism is almost invisible when its longitudinal axis is at right angles to the plane of polarisation of the prism, and becomes more and more visible when the stage is rotated, until it reaches a maximum of visibility at right angles to the original position. Artificial silk fibres have a refractive index considerably below that of aniline and are distinctly visible at all positions of the revolving stage.—J. F. B.

Rape straw as a paper and fodder material. E. Heuser and T. Blasweiler. *Papier-Zeit.*, 1918, 43, 593, 613. *Chem.-Zeit.*, 1918, 42, Rep., 108.

THE examination of the rape plant showed, on the dry substance, cellulose, 30.31; pentosans, 24.10; lignin, 40.06, and ash, 5.53%. The composition of the plant substance is somewhat similar to that of cereal straw, which suggests that rape, like straw, might be used as a raw material both for paper pulp and for fodder. A pulp prepared by the soda process had the composition: cellulose, 55.60; pentosans, 30.50; lignin, 10.10; ash, 3.77%. In consequence of the higher proportion of lignin in the rape straw as compared with cereal straw, a sharper treatment is necessary in order to obtain

a similar degree of resolution. The pulp would be described from a technical point of view as a "half-cellulose," such as is employed for the manufacture of boards.—J. F. B.

Utilisation of rice and its by-products. See XIXA.

PATENTS.

Textile fabrics, wood, leather, and other materials; Treatment of —. W. M. Gillard, Chelsfield, and M. Heslam, Upper Holloway. Eng. Pat. 117,640. (Appl. Nos. 5769, Apr. 24, and 14,675, Oct. 10, 1917.)

IN order to render material such as canvas, wood, leather, etc., more suitable for the reception of photographic prints, hand painting, etc., it is coated with a preparation containing a filling material such as kaolin, a binding medium such as gelatin, and substances such as formaldehyde and glycerin, to impart insolubility and flexibility. —B. V. S.

Wool scouring or like effluents or liquors; Process for the separation of grease from —. G. G. Jarman, Huddersfield. Eng. Pat. 118,332, Aug. 25, 1917. (Appl. No. 12,220 of 1917.)

Wool scouring liquor or other effluent containing grease is first passed, preferably just below the boiling temperature, through a hydro-extractor or centrifugal filter in order to separate the sand and heavy foreign impurities, and is then delivered, preferably from an overhead feed tank into which the filtered liquor is pumped, to a cylindrical or bowl centrifugal separator, having a feed jet and baffle-plate at the bottom, in which the grease is separated from the aqueous layer and both are discharged through separate delivery channels at the top.—J. F. B.

Fibre; Method of treating vegetable —. M. W. Marsden, Philadelphia, Pa. U.S. Pat. 1,269,476, June 11, 1918. Date of appl., Feb. 6, 1917.

FOR the manufacture of pulp, the incrusting and other difficultly soluble bodies are removed by subjecting the prepared stock to the solvent action of a mixture of sodium chloride and lime in the presence of heat, moisture, and pressure.—J. F. B.

Fibre plants and woody material; Process of retting, degumming, and drying —. B. Loomis, Hartford, Conn. U.S. Pat. 1,271,591, July 9, 1918. Date of appl., Aug. 2, 1915.

THE material is placed in layers on grids in a closed tank, and hot water and fatty acid solvents including acetic acid are circulated around and between the layers until the gummy and resinous matter has been released; this is floated off and separated from the water, and the solvent liquor is repeatedly reheated and circulated through or in contact with the fibre material until retting and degumming are completed.—J. F. B.

Fibre; Process for treating —. R. R. Roberts, Washington, D.C., Assignor to United Textile Co. U.S. Pat. 1,272,851, July 16, 1918. Date of appl., July 30, 1917.

THE fibres are boiled under pressure in an alkaline solution containing kerosene, then treated in an acid bath, washed in a saponaceous solution, rinsed, and dried.—J. F. B.

Silk; Process for degumming — L. Elkan Erben Ges., Charlottenburg. Ger. Pat. 305,920, Aug. 26, 1917.

SOLUTIONS of "lignic acid" are employed in the degumming baths.—J. F. B.

Cuprammonium cellulose solutions for artificial threads; Preparation of stable — by the use of sugars. Glanzfäden Akt.-Ges., Petersdorf. Ger. Pat. 306,107, Oct. 13, 1917.

MONOHYDROSE sugars of the dextrose group are employed in the cuprammonium solutions as well as sugars of the sucrose group, in such quantities that the spinning qualities of the solutions are not impaired. Even at normal temperature the monosaccharides exert a reducing action which impedes the oxidation of the copper compound and the cellulose during the preparation of the solution, so that the solubility of the copper oxide in ammonia is greater and the cellulose dissolves more rapidly and completely; the stability of the cellulose solution is also improved. A proportion of 0.25% of starch glucose or invert sugar calculated on the weight of the cellulose is sufficient to counteract the tendency to oxidation during the preparation of the cellulose solution.—J. F. B.

Pulp [from bracken] for making paper, paper boards and the like; Manufacture of — W. T. Moore, Bromley, Kent. Eng. Pat. 118,291, Sep. 12, 1917. (Appl. No. 3651 of 1917.)

BRACKEN is collected either in the autumn during the withering period or in the winter when the fronds are dead, and the pinnae and pinnales (primary and secondary leaflets) are stripped off the stems by drawing the fronds through an aperture formed by two plain or toothed pieces of wood or metal placed parallel in the same plane, in a frame, at a suitable distance apart. The leaflets fall on one side of the frame and the stems on the other side. The leaf material is boiled separately with water without pressure and without the use of alkali, and the stems are digested, preferably without pressure, with 5–10% of their weight of soda, preferably in the form of caustic soda. The two materials are broken-in, beaten, bleached, and washed and may be blended together at any stage after the breaking process.—J. F. B.

Treating to an impregnating fluid, particles of non-uniform moisture content; Apparatus for — [e.g. in the preparation of wood pulp]. G. H. Hess, La Grange Park, Ill. U.S. Pat. 1,265,330, May 7, 1918. Date of appl., May 17, 1917.

THE apparatus comprises a dryer in which the material, e.g., wood chips, is partially dried; a bin in which the partially dried material is retained until the moisture content becomes uniform throughout; a storage bin to receive the contents of the preceding bin, and a vessel in which the material is subjected to the action of an impregnating fluid, e.g., a digester for the manufacture of wood pulp.

Paper pulp; Manufacture of — S. D. Wells, Madison, Wis. Dedicated to the Government and people of the United States. U.S. Pat. 1,269,350, June 11, 1918. Date of appl., Apr. 30, 1918. (Dedicated to the public.)

IN the process of digesting wood or other fibrous material, the desired amount of moisture is introduced into the digester during the process, in direct combination with the steam, whereby the cellulose is protected to a marked degree from the action of the digestion liquors, while their action on the incrusting matters is not diminished.

—J. F. B.

Paper; Safety — E. E. Schmidt, Boston, Mass., Assignor to Paramount Safety Paper Co., Chicago, Ill. U.S. Pat. 1,269,863, June 18, 1918. Date of appl., Feb. 6, 1917.

THE paper is coated with a composition containing ingredients capable of being decomposed by acid and alkaline ink eradicators to release substances which stain the paper and to render writing ink containing iron indelible. Suitable ingredients are a soluble ferrocyanide, an iodide, glycerin, ox-gall, tapioca flour, and caustic soda; the ox-gall is for the purpose of rendering the paper permeable to the composition.—J. F. B.

Paper containing salicylic or benzoic acid; Manufacture of — L. Elkan Erben Ges., Charlottenburg. Ger. Pat. 305,956, June 27, 1917.

PAPER is treated with easily soluble salts of salicylic or benzoic acid. The absorption by the fibre is so complete and permanent that no visible efflorescence of crystals occurs.—J. F. B.

Paper textiles; Process for cleaning old — T. Goldschmidt A.-G., Essen. Ger. Pat. 306,000, Sep. 12, 1917. Addition to Ger. Pat. 305,427 (this J., 1918, 410 A).

AFTER cleansing with bleach liquor or chlorine water, any looseness of texture produced by the treatment is corrected by impregnating the textiles with a mixture of gelatin solution and glycol, before finishing by mechanical treatments.

—J. F. B.

Cardboard; Process for rendering grease- and waterproof. L. Buchbinder, Vienna. Ger. Pat. 306,028, Dec. 2, 1917.

THE proofing composition consists of a mixture of a glue precipitate with a decoction of Iceland moss containing gypsum ("Federweiss") or magnesia, or with a concentrated alcoholic solution of resin. The composition is applied warm, e.g. with a brush in the case of containers intended for fatty substances which readily solidify, or by filling the container with the composition and pouring out after 3–4 minutes, in the case of those intended for substances of low melting point. The coating must be dried at the ordinary temperature. The mixture of magnesia and glue-tannin fills up the pores of the paper and makes the container watertight; if it has to withstand mineral oil, a second coating of waterglass is applied. An alternative method consists in treating the cardboard with a mixture of precipitated glue and magnesia and then soaking in a decoction of Iceland moss containing formaldehyde.—J. F. B.

Drying paper, pasteboard, wood-pulp, and other materials; Apparatus for — L. A. Lyeche, Sandviken, Norway. U.S. Pat. 1,271,738, July 9, 1918. Date of appl., Oct. 12, 1917.

SEE Eng. Pat. 5855 of 1915; this J., 1916, 41.

Collodion coating for incandescence mantles. Ger. Pat. 306,103. See IIB.

PATENTS.

Kiers; Vomiting —. E. D. Jefferson, Boston, Mass., U.S.A. Eng. Pat. 112,260, Sep. 26, 1917. (Appl. No. 13,894 of 1917.) Under Int. Conv., Dec. 29, 1916.

A vomiting kier of the type described in Eng. Pat. 25,307 of 1904 (U.S. Pat. 772,450; this J., 1904, 1202) is provided with an external trap into which the liquor accumulating at the bottom of the kiers can penetrate through a non-return valve. The top of the trap is connected with a mechanically time-controlled valve through which a determined quantity of high-pressure steam is admitted at intervals above the liquid collected in the trap. An external vomit-pipe leads from the bottom of the inside of the trap into the top of the kiers, and the liquid is forced up by the steam pressure and sprayed over the top of the goods. A narrow vent pipe is provided between the top of the trap and the top of the kiers to equalise the pressure when the trap is filling up. A battery of kiers may be arranged with the steam valves of all the kiers controlled at one place by a single motor, with means for throwing the control mechanism of any kiers out of action.—J. F. B.

Mordanting of vegetable fabrics and fibres. The Calico Printers' Association, Ltd., and F. Ashton, Manchester. Eng. Pat. 117,715. (Appl. Nos. 12,510, Aug. 31, 1917, and 3287, Feb. 25, 1918.)

Chromium mordants, either alone or in conjunction with other mordants, are fixed on vegetable fibres by first preparing the fabric in a solution of a chromium salt and subsequently immersing in a caustic soda solution of a minimum density of 20° Tw. (sp. gr. 1.10) and allowing the material to lie batched or piled long enough to complete the fixation. If desired, the material, after the treatment with caustic soda, may be subjected, without drying, to the action of steam before batching or piling.—J. F. B.

Aniline Black upon vegetable fibres; Production of —. The Calico Printers' Association, Ltd., and E. A. Fourniaux, Manchester. Eng. Pat. 117,987, Aug. 31, 1917. (Appl. No. 12,509 of 1917.)

For the production of Aniline Black developed by drying with hot air or "ageing" and after-treatment with sodium chromate, the ingredients mentioned in Eng. Pat. 116,562 (this J., 1918, 463A) are mixed within the limits of the following molecular proportions:—The primary arylamines other than aniline should not exceed 3 mols. out of a total 11 mols. of amines; the proportion of strong mineral acid should not exceed one-half of that required to

neutralise completely the bases used; for 1 mol. of aniline or the equivalent mixture of bases, the boric acid may range from 0.4 to 1.0 mol., the formic acid should not be less than 0.75 mol., the organic catalyst (*p*-phenylenediamine or *p*-aminophenol) not less than 0.03 mol., the soluble copper salt not less than 0.1 mol., and the chlorate between 0.3 and 0.45 mol. Suitable thickening agents are made into a paste and boiled with a little formic acid; the aniline, the acids, and the salts of the bases are then dissolved in the warm thickening, and the sodium chlorate in solution is added after cooling; the copper salt is added only immediately before use.—J. F. B.

Beam dyeing machine. E. and L. Holt, Burlington, N.C. U.S. Pat. 1,269,934, June 18, 1918. Date of appl., July 1, 1915.

A PERFORATED beam for holding a quantity of warped or wound yarn is mounted in a closed vat, and liquid is circulated from the inside to the outside of the beam and *vice versa*. Means are provided for introducing compressed air above the surface of the liquid for simultaneously forcing the treating agents from the vat and for oxidising them on the yarn as they escape from the vat; means are also provided for introducing compressed air into the bottom of the beam.—J. F. B.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,271,144, July 2, 1918. Date of appl., Aug. 3, 1917.

WITHIN a receptacle having non-perforated sides are two foraminous plates, spaced apart, each plate comprising a series of extended hollow cones having vertical openings in the sides. A distributing chamber converging downwards is spaced below the lower foraminous plate, and contains a series of parallel curved blades converging downwards and inwards. A pump for forcing liquid through the apparatus is connected with the lower portion of the distributing chamber and an overflow pipe is provided above the upper foraminous plate. A smaller testing device exterior to the dyeing chamber, similar and proportionate to the larger vessel, is connected with the latter below the lower foraminous plate.—J. F. B.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,271,549 and (B) 1,271,550, July 9, 1918. Dates of appl., May 16 and June 30, 1917.

(A) A RECEPTACLE contains a series of revolving fibre chambers each having foraminous walls with members extended inwards, and with openings between the members, a foraminous member spaced from the inner wall of the fibre chamber and integral therewith, a series of tubes, each tube of which opens upon a portion of the inner face of the foraminous member and extends outwards through the hollow core of the device, and a second series of similar tubes extending through the core in the opposite direction. Means are provided for maintaining the fibre chambers beneath a liquid within the receptacle, for continuously passing a liquid through the tubes and fibre chambers, for passing air through them, and for revolving the fibre chambers, foraminous member, and tubes. (B) A dyeing chamber contains a series of fibre chambers each comprising a foraminous bottom having non-perforated sides and members extending upwards, and a foraminous top plate to each series of fibre chambers having members extending downwards. There are also a reserve tank, the upper portion of which is connected with the upper and lower portions of the dyeing chamber and the lower portion with a pump, a second dyeing chamber adjacent to the first and connected thereto at the top and the bottom, and means for passing a liquid through the fibre chambers in opposite directions.

—J. F. B.

Fabrics; Method for sponging, setting, and finishing — E. Heldler, Garfield, N.J., Assignor to Columbia Conditioning Co., Inc., New York. U.S. Pat. 1,270,153, June 18, 1918. Date of appl., Aug. 9, 1916.

Fabric in the width is unrolled and passed with a continuous travelling motion through the following operations in the sequence stated: brushing both faces of the fabric, heating it by exposure to the action of steam, sponging it with water, heating it by passing round a heated surface, ironing it on both faces by heated cylinders running in the opposite direction to the travel of the fabric, allowing the fabric to accumulate in folds, subjecting the fabric to tension, supplying steam to the fabric, cooling it gradually and supplying it with a natural amount of water by passing it over moistened rollers, spreading it in a transverse direction, and finally winding up the fabric in finished condition.—J. F. B.

Sericin soap; Manufacture of a substitute for — [for use in silk dyeing]. Gebr. Schmid, Basle, Switzerland. Eng. Pat. 117,042, Jan. 14, 1918. (Appl. No. 805 of 1918.) Under Int. Conv., Sep. 4, 1917. Addition to Eng. Pat. 100,169, Mar. 12, 1915 (this J., 1916, 734).

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Manufacture of — by the ferric oxide contact process. H. Ditz and F. Kanhäuser. Z. angew. Chem., 1918, 31, 149–150, 153–156.

In the manufacture of sulphuric acid by the ferric oxide contact process (this J., 1902, 1137; 1905, 729; 1908, 402) the burner gases are first brought into contact with ferric oxide at a high temperature, 50 to 60% of the sulphur dioxide being converted into sulphur trioxide, whilst the arsenic is retained by the contact mass. The gases are then cooled, and, after absorption of the sulphur trioxide by means of sulphuric acid, are brought into contact with a platinum mass whereby the oxidation is completed. Samples of sulphuric acid deposited in the fan casing of a plant had the following composition:—Sulphuric acid, 97.82 and 97.01; lead sulphate, 1.28 and 1.04; selenium, 0.104 and 0.006; selenium dioxide, 0.161 and 0.058; selenic acid, 0.008 and 0.014; arsenious oxide, 0.014 and 0.007; and sulphur dioxide, 0.012 and 0.064% respectively. Experiments to determine the volatility of lead sulphate showed that when heated with sulphuric acid alone, it was only slightly volatile, but that in the presence of selenium, especially in the elementary form or as SeO_2 , the volatility was greatly increased. The high proportion of lead in the acid was contrary to recorded statements. According to Lunge 100 parts of sulphuric acid of sp. gr. 1.841 dissolves 0.039 part of lead sulphate, whilst Marshall gives the solubility in 98% acid as 0.09%, but the authors have shown (this J., 1917, 641) that 98 to 100% sulphuric acid is able to dissolve a large proportion of lead. The variations in the proportions of selenium in the acid are attributable to the variable composition of the pyrites or to variations in the working of the plant. The presence of selenium has probably an unfavourable influence on the oxidation of the

sulphur dioxide. The process should convert up to 95% (usually about 92%) of the sulphur burned, but in a plant studied by the authors the yield was sometimes less than 90%. This was probably partly due to the toxic action of the arsenic in the gases upon the platinum contact mass, but it was also possible that selenium and lead compounds in the burner gases had an influence on the activity of the ferric oxide contact mass.—C. A. M.

Sodium sulphate, ammonium sulphate and water; The ternary system —. Utilisation of nitre cake for the production of ammonium sulphate. H. M. Dawson. Chem. Soc. Trans., 1918, 113, 675–688.

WHEN finely powdered Glauber's salt and ammonium sulphate are brought into intimate contact at the ordinary temperature, a pasty mass is obtained and the temperature of the mixture falls considerably. This is due to the formation of sodium ammonium sulphate: $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O} + (\text{NH}_4)_2\text{SO}_4 = \text{Na}_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 4\text{H}_2\text{O} + 6\text{H}_2\text{O}$. The lowest temperature at which this reaction occurs is -16°C . Above 59.3°C . the double salt decomposes with the formation of the anhydrous simple salts. The composition of the saturated solutions which characterise the ternary system has been determined at temperatures between -19.5°C . (the eutectic temperature) and 100°C . The solutions which are saturated simultaneously with respect to the double salt and sodium sulphate show a very pronounced minimum in the ammonium sulphate content and a maximum in the sodium sulphate content at 26.5°C ., which is the temperature at which Glauber's salt is transformed into anhydrous sodium sulphate in presence of the double salt. Although the double salt may be crystallised out from solutions containing the mixed sulphates at any temperature between -16°C . and 59.3°C ., if the ratio between the salts is suitably adjusted, yet the double salt is decomposed by water between -16° and 20°C . with the separation of Glauber's salt, and between 41.5° and 59.3°C . with the separation of anhydrous sodium sulphate. Saturated solutions of the double salt containing equivalent quantities of sodium and ammonium sulphate are only obtainable, in the absence of supersaturation, between 20° and 41.5°C . In view of the fact that solutions saturated with respect to Glauber's salt and ammonium sulphate (or the double salt) at low temperatures contain a large excess of ammonium sulphate, it is possible to crystallise out a large proportion of sodium sulphate from a solution containing the two sulphates by cooling. If the mother liquor is subsequently evaporated at about 100°C . pure ammonium sulphate may be obtained so long as the ratio of ammonium sulphate to sodium sulphate in the residual hot liquor does not fall below about 2.7. By repeating the cooling and evaporating processes, complete separation of the sodium and ammonium sulphates may be effected. By the use of this process it is possible to make use of nitre cake for the absorption of ammonia in the production of ammonium sulphate, Glauber's salt being obtained as a by-product—H. M. D.

Nitre cake; Use of — in the manufacture of sulphate of ammonia. P. Parrish. Gas J., 1918, 143, 395–396.

IN order to produce a saleable mixed sodium and ammonium sulphate, the method has been successfully adopted at the Stafford Gas-Works of introducing ground solid nitre cake into the acid-charge pot. The following precautions were found necessary for the satisfactory application of the method: The sulphuric acid content of the bath should not

be allowed to fall below 6%, as determined by titration; the nitre cake should be added regularly; frequent tests should be made to ascertain the presence of undecomposed nitrates, which results in corrosion of the lead. As an alternative to the introduction of the solid cake, it is suggested that it might be dissolved in the feed acid in lead-lined tanks, provided the nitre cake is sufficiently pure and the acid free from arsenic. The method adopted at the Llwynpia works of the Glamorgan Coal Co. is to feed a nitre cake solution of 6% sulphuric acid content along with the free acid in certain fixed proportions into the saturator. As soon as deposition of crystals begins in the saturator, as indicated by an excess back pressure, some of the liquor is run into the mother liquor well, where, on cooling to 46° C., practically the whole of the sodium sulphate crystallises out. A further supply of solution is then run into the saturator. The mother liquor containing ammonium bisulphate and small quantities of sodium bisulphate, is again introduced into the cycle of operations. Ammonium sulphate containing 23.8% NH_3 is obtained as the final product. Trial has been made on a Mond recovery plant at Langwith of the exclusive use of nitre cake for extraction of the ammonia. The cooled gases, freed from tar, are scrubbed in a tower with a 3 to 4% sulphuric acid solution. On reaching the saturation point, the solution is evaporated to crystallise out the ammonium sulphate. The mother liquor, maintained at about 80° C. is used to wash the nitre cake, the conditions being such that very little sodium sulphate goes into solution. The liquor is then used again in the tower, diluted with washings from the sodium sulphate sludge. Ammonium sulphate containing 24.5% NH_3 is thus obtained.

—L. A. C.

Chlorine; Determination of — in mixtures containing silicates. G. Bruhns. *Z. angew. Chem.*, 1918, 31, 156.

CHLORINE may be determined by titration with silver nitrate in the presence of dissolved or gelatinous silicic acid (water glass, detergents, etc.), provided that the liquid is made neutral to phenolphthalein with nitric acid and any resulting gelatinous mass is finely distributed by trituration or shaking.—C. A. M.

Chlorates, peroxides, etc.; Source of error in Bunsen's method for the determination of —. E. Rupp. *Z. anal. Chem.*, 1918, 57, 226–230.

THE results obtained by this method are from 0.5 to 2% too low when the substance is distilled directly with hydrochloric acid, the chlorine collected in potassium iodide solution, and the liberated iodine titrated. This is due to reaction between chlorine and steam with the formation of hydrochloric acid and oxygen. Better results are obtained when potassium iodide is added to the distillation mixture and the iodine distilled over and titrated, since iodine does not decompose water vapour. The concentration of the hydrochloric acid has an influence, however, and the results in some cases tend to be too high owing to slight decomposition of the iodide by hydrochloric acid. To obtain concordant results the distillation must always be carried out under the same conditions.

—W. P. S.

Nitrates and nitrites; Estimation of —. W. Strecker. *Ber.*, 1918, 51, 997–1004.

THE solution to be analysed, containing nitrites and nitrates equivalent to not more than 0.11 grm. NaNO_2 and 0.18 grm. KNO_3 , is dropped into a boiling, concentrated solution of ammonium

chloride, at least 100 times as much of this salt being taken as there is nitrite present, the solution being in a flask which is connected with an apparatus for making air-free carbon dioxide, on the one hand, and a water-cooled Schiff's nitrometer, containing potassium hydroxide, on the other. After adjusting the pressure and noting the volume of nitrogen, a solution of iron in concentrated hydrochloric acid is introduced and the nitric oxide is collected.—J. C. W.

Vanadium compounds; Quantitative analysis of — with the aid of carbon tetrachloride. P. Jannasch and H. E. Harwood. *J. prakt. Chem.*, 1918, 97, 93–137.

VANADIUM in various vanadium compounds can be estimated by heating the latter in a current of carbon dioxide and carbon tetrachloride vapour. The compound is placed in a silica boat inside a silica tube and the resulting volatile vanadium oxychloride and tetrachloride are collected by passage into two receivers containing dilute nitric acid and water respectively. The resulting solution of vanadic acid is evaporated to dryness, the residue being subsequently dissolved in dilute sulphuric acid, treated with a slight excess of potassium permanganate to remove traces of organic matter, and then reduced by a current of sulphur dioxide. After the expulsion of the excess of sulphur dioxide by boiling, the vanadyl sulphate which remains is estimated by titration at 70° C. with potassium permanganate solution. A repetition of the reduction and titration may be made with the same solution. The reaction may be expressed:

Details are given of the conditions necessary for the satisfactory decomposition of various vanadium compounds by carbon tetrachloride. It is also possible to expel phosphoric acid from sodium phosphate by heating a mixture of the latter with sodium chloride or silica in carbon tetrachloride vapour; boric acid and titanate acid can be displaced in a similar manner, but the details necessary to render the process capable of application to quantitative analysis are not yet completed.

—D. F. T.

Hydrogen peroxide; Neutralisation of — with sodium borate. J. Cambe and H. Diacono. *J. Pharm. Chim.*, 1918, 18, 12–17.

CERTAIN samples of hydrogen peroxide when mixed even with an excess of sodium borate did not give a red coloration to phenolphthalein. These samples contained hydrofluosilicic acid or were freshly prepared and contained "active" oxygen, and the non-appearance of the red coloration of the phenolphthalein when sodium borate was added was due to the presence of these substances; other indicators were not affected. (See also *J. Chem. Soc.*, Oct., 1918.)—W. P. S.

Bismuth tellurides. H. M. Amadori. *Atti R. Accad. Lincei*, 1918, 27, I., 131–134.

THERMAL investigation shows that fused mixtures of Bi , Bi_2S_3 , and Bi_2Te_3 give no compounds analogous to the natural sulphotellurides, tetradimite, grunlingite, and joseite. (Compare *J. Chem. Soc.*, Oct., 1918.)—T. H. P.

Silicon hydrides. V. Decomposition of silicon hydrides by water. Action of hydrogen bromide on monosilane. A. Stock and C. Somieski. *Ber.*, 1918, 51, 989–996.

THE silanes (silicon hydrides) are practically unaffected by water during several days, unless the

glass renders the mixture alkaline, when they decompose in a few hours into hydrogen and silicic acid. Monosilane reacts very readily with hydrogen bromide in the presence of aluminium chloride to give the lower bromides, thus: $\text{SiH}_4 + \text{HBr} = \text{SiH}_3\text{Br} + \text{H}_2$, and $\text{SiH}_4 + 2\text{HBr} = \text{SiH}_2\text{Br}_2 + 2\text{H}_2$. A mixture of monosilane, hydrogen bromide, and bromomonosilane can be analysed by means of water. The last-named reacts immediately to form the gas disiloxane, which decomposes after two or three hours into silica and hydrogen, thus: $2\text{SiH}_3\text{Br} + \text{H}_2\text{O} = (\text{SiH}_3)_2\text{O} + 2\text{HBr}$;

If the volume of the mixture is a , the volume after the initial contraction is b , and the final volume is c , then $c-b$ gives the volume of SiH_3Br , and $a-b-\frac{1}{2}(c-b)$ the volume of HBr . (See further J. Chem. Soc., Oct., 1918.)—J. C. W.

Catalysts; Influence of foreign substances on the activity of —. V. *Experiments with palladium hydrosol in the presence of the hydroxides of iron, copper, and zinc.* C. Paal and W. Hartmann. Ber., 1918, 51, 894–906. (Compare this J., 1918, 560 A.)

THE hydroxides mentioned are peptised by sodium protoborate but differ in their influence on the activity of palladium hydrosol, protected by this colloid, in the union of hydrogen and oxygen. Ferric hydroxide has no action at all. Precipitated copper hydroxide lowers the activity of the catalyst but large quantities would be necessary to spoil it altogether; colloidal copper hydroxide actually causes an increase in the activity of the palladium at first, but this is followed by a rapid decrease. Zinc hydroxide depresses the activity during the first hour to about one-half, but a remarkable recovery ultimately takes place, and the catalyst actually becomes more than normally active. (See further J. Chem. Soc., Oct., 1918.)—J. C. W.

Iodine; Enrichment of — during its purification. F. Lenzi. Boll. Chim. Farm., 1918, 57, 121–123.

IN the purification of iodine, sublimation removes most of the cyanogen iodide—which sublimes first—and also of the bromine and moisture. Chlorine and bromine are eliminated by sublimation in presence of potassium iodide. The loss of iodine accompanying these processes may be avoided as follows (see Tarugi, this J., 1918, 284 A). When qualitative analysis indicates the presence of iodine monochloride and iodic acid, the water used for washing the iodine is treated with an acid (sulphuric) solution of ferrous sulphate. If, however, cyanogen iodide is present, the washing water is first left in contact with a sufficient quantity of iodine monochloride for 24 hours and then treated with the acid ferrous sulphate in the usual way. If the iodine contains iodine bromide, this is converted into hydrobromic acid and iodine by the ferrous sulphate.—T. H. P.

Effect of the iron content of ammonium persulphate on its photographic reducing power. Sheppard. See XXI.

PATENTS.

Sulphuric acid; Manufacture of — from nitre cake. F. A. Freeth, Northwich. Eng. Pat. 117,649, June 29, 1917. (Appl. No. 9347 of 1917.)

NITRE cake, calcium sulphate, and water are mixed in suitable proportions (e.g., 689:180:313) and heated to 50° C. with constant stirring until a solution saturated with sodium bisulphate, the double salt $\text{CaSO}_4 \cdot \text{Na}_2\text{SO}_4$, and calcium sulphate is produced. The precipitated double salt containing some calcium sulphate is separated and the

solution cooled to 25° C. until sodium bisulphate separates out. This is removed and the solution is concentrated until it contains 70–75% of sulphuric acid and is then cooled to 25° C., the remaining sodium sulphate being deposited as $\text{Na}_2\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$. After separation of this substance the solution contains 75–80% of sulphuric acid with less than 1% of sodium sulphate. The sodium bisulphate and the $\text{Na}_2\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ are treated with more calcium sulphate and the cycle of operations repeated. The double salt $\text{CaSO}_4 \cdot \text{Na}_2\text{SO}_4$ is decomposed by extracting it with hot water, the sodium sulphate going into solution and the greater part of the calcium sulphate remaining insoluble. Temperatures much higher or lower than 50° C. are unfavourable to the main reaction.—A. B. S.

Sulphuric anhydride and the like; Apparatus for the manufacture of —. E. L. Wilke, Buffalo, N.Y. U.S. Pat. 1,270,997, July 2, 1918. Date of appl., Oct. 4, 1916.

SULPHUR dioxide gas is passed tangentially into an outer annular chamber at a point midway of its height, and passes into an inner chamber containing a heated contact material, through a number of passages opening into the upper end of the outer chamber and into the lower end of the inner contact chamber. Dust separates from the gas in the outer chamber. The outlet for gases leaving the inner contact chamber is provided with a damper to control the pressure in the chamber, the volume of gas passing being kept constant.

—A. B. S.

Metallopyrophosphoric acids or their salts associated with boron compounds or containing boron; Manufacture of — and the application of the products in tanning. B. Levin, Hale, Chester. Eng. Pat. 117,693, Aug. 3, 1917. (Appl. No. 11,224 of 1917.)

METALLOPYROPHOSPHORIC acids containing boron or their salts may be made by heating pyrophosphoric acid (Eng. Pat. 116,735; this J., 1918, 416 A) or a mixture of boric acid and pyrophosphoric acid with a compound of a suitable metal such as chromium, aluminium, iron, tungsten, or manganese at a temperature not exceeding 300° C. For example, a chromium salt, such as chrome alum, is mixed with boric oxide and commercial orthophosphoric acid in the proportions Cr: B: P_2O_5 = 52: 44: 600 and heated until a heavy mobile mass is obtained and the temperature exceeds 250° C. The product is poured on to trays which are heated until a substantially anhydrous mass is obtained. The products are less hygroscopic and more stable than the metallopyrophosphates previously known. In tanning, the use of a metallopyrophosphoric acid containing boron and a metal known to have a tanning action is advantageous, because it is more soluble, and has a greater penetrative power than ordinary pyrophosphates and may be rendered insoluble in the pores of the hides by neutralising the acidity of the tan-liquor.—A. B. S.

Potassium compounds; Manufacture of —. S. R. Scholes, Beaver, Pa., U.S.A. Eng. Pat. 117,755, Nov. 5, 1917. (Appl. No. 16,157 of 1917.)

FELSPAR or other potash-bearing mineral is reduced to a fine powder and mixed with sufficient hydrated potassium or sodium carbonate to supply one equivalent of K_2O or Na_2O to every two equivalents of SiO_2 . The mixture is fused, poured into water, and then ground to powder. The product is boiled with water, and crude carbon dioxide or waste gas rich in carbon dioxide is passed through

the mixture until the amount of dissolved alkali has reached a maximum. The liquid is filtered, the filtrate evaporated, and the potassium and sodium carbonates recovered. When sodium carbonate is used, an amount of the evaporated product equal in weight to the sodium carbonate employed may be added to a fresh quantity of rock and the process repeated. By this means, the proportion of potassium carbonate in the evaporated product will be increased from about 20% to about 40%. This re-use of part of the evaporated product may be repeated five or six times until most of the sodium present has been eliminated, after which only potassium carbonate is added to fresh charges. Alternatively the mixed sodium and potassium carbonates may be separated by evaporating the solution until a concentration is reached at which most of the sodium carbonate crystallises out. The filtered solution is then evaporated to dryness and the product used for treating fresh quantities of potash-bearing mineral as previously described. An important feature of the process is the removal at the end of each cycle of a quantity of mixed carbonates equal to the amount of potassium carbonate extracted from the rock.—A. B. S.

Potassium salts; Process for the recovery of — from blast furnace flue dust or the like. Stafford Coke and Iron Co., Ltd., and J. R. Richmond, Stoke-on-Trent. Eng. Pat. 117,991, Sept. 8, 1917. (Appl. No. 12,887 of 1917.)

BLAST-FURNACE flue dust is extracted with hot water in a suitable apparatus, e.g., a hydro-extractor, steam-heated tanks, etc., and the filtered solution is blown with air and treated with lime until it shows an alkaline reaction, whereby iron, manganese, and magnesium are precipitated, after which it is evaporated to dryness. The residue is baked, thus removing any soluble organic matter and rendering the iron insoluble, re-dissolved in water and filtered. The clear solution is evaporated until crystallisation begins, when it is allowed to cool. High-grade potassium salts crystallise out, and, after separation of the crystals, further quantities of crude salts may be obtained by evaporation of the mother liquor. Ammonia may be recovered, either as the chloride by heating the dust before extraction, or, as gas, when lime is added to the liquor.—L. A. C.

Potassium aluminate, alumina, and potassium carbonate; Manufacture of —. E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 118,155, Aug. 18, 1917. (Appl. No. 11,887 of 1917.)

A POWDERED mixture of potassium chloride (450 parts), bauxite or any aluminous substance (e.g., calcined bauxite containing about 70% Al_2O_3 , 400 parts), calcium hydroxide (222 parts), and coke (40 parts) is heated to redness in a retort or muffle, and 133 parts of arsenic trioxide vapour is introduced. Arsenic trichloride, potassium aluminate, hydrogen, and calcium carbonate are produced. The potassium aluminate is removed by lixiviation and aluminium hydroxide precipitated from the solution by passing in carbon dioxide. The potassium carbonate solution remaining after filtration of the alumina is evaporated to dryness.

—J. H. P.

Sodium aluminate, alumina, and sodium carbonate; Manufacture of —. E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 118,156, Aug. 18, 1917. (Appl. No. 11,888 of 1917.)

In the process described in Eng. Pat. 118,155 (see preceding abstract) sodium chloride (351 parts) is used in place of potassium chloride.—J. H. P.

Borates; Method of separating — from their gangue. H. W. Faulkner, Ryan, Cal., Assignor to Pacific Coast Borax Co., Reno, Nev. U.S. Pat. 1,269,170, June 11, 1918. Date of appl., June 26, 1917.

A MIXTURE of borate and gangue is dehydrated by heat to such a degree that the specific gravity of the borate is altered, and the two components are then separated, if necessary after crushing, by subjecting the mixture to a jigging operation, dependent on the specific gravities of the components.

—E. W. L.

Aluminium chloride; Process of making —. D. F. Smith and H. Essex, Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,270,226, June 18, 1918. Date of appl., June 22, 1917.

A MATERIAL containing alumina is heated with carbon in an electric furnace so as to form aluminium carbide and dissociated aluminium carbide, and the product is treated with a gas containing chlorine, under such conditions that aluminium chloride is produced, vaporised, and condensed in another part of the apparatus used. No external heating is required for the conversion of the carbide into chloride.—A. B. S.

Ammonia; Apparatus for the catalytic oxidation of —. M. Taliani, Isola Liri, Italy. U.S. Pat. 1,270,989, July 2, 1918. Date of appl., Apr. 26, 1918.

THE catalytic material is placed in the middle of a chamber comprising two funnel-shaped chambers united at their larger ends. Air and ammonia are admitted at one of the smaller ends and are given a whirling motion which mixes them and distributes them uniformly over the catalyst. A cooling coil may be fitted inside the apparatus, close to the catalyst. A valve is provided for controlling the pressure in the chamber.—A. B. S.

Ferrie phosphates; Process of producing —. W. H. Allen, Detroit, Mich. U.S. Pat. 1,271,002, July 2, 1918. Date of appl., Sep. 25, 1916.

FINELY divided currents of air are passed through an aqueous solution of ferrous phosphate and phosphoric acid so as to oxidise the ferrous salt to ferrie phosphate.—A. B. S.

Perechloric acid; Method of electrolytic production of —. E. C. Walker, Brookline, Mass. U.S. Pat. 1,271,633, July 9, 1918. Date of appl., Apr. 23, 1917.

A SOLUTION of hydrochloric acid, of strength not greater than N/1, is subjected in successive stages to electrolytic action with a current-density of 0.5 amp. per sq. cm., and at a temperature not materially exceeding 50° C. in the initial stage, the temperature being reduced considerably in a subsequent stage. A flow of electrolyte is maintained through the initial stage, to and through the subsequent stage, and the perchloric acid solution so produced is finally concentrated.—L. A. C.

Ammonium perchlorate; Method of producing —. G. C. Given, Tamaqua, Pa., Assignor to Atlas Powder Co., Wilmington, Del. U.S. Pat. 1,273,477, July 23, 1918. Date of appl., Sep. 10, 1917.

AMMONIUM perchlorate is produced by the interaction of a soluble perchlorate such as sodium perchlorate, with carbon dioxide in presence of ammonia, or by the action of ammonium bicarbonate on a soluble perchlorate.—J. H. P.

Silicon tetrachloride; Method for the production of — O. Hutchins, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,271,713, July 9, 1918. Date of appl., Oct. 30, 1917.

Dry chlorine is passed through a mass of silicon carbide heated electrically to at least 1000° C.

—L. A. C.

Sulphur dioxide from furnace gases; Method of recovering — H. Howard, Brookline, and F. G. Stantlat, Melrose, Mass. U.S. Pat. 1,271,899, July 9, 1918. Date of appl., May 12, 1917.

Non-oxide substances, e.g., sulphur trioxide, are precipitated from the furnace gases, and the residual gases scrubbed with a dilute alkaline solution. The solution is then treated with lime, producing calcium sulphite and an alkaline solution, which is used for the treatment of further quantities of the gas.—L. A. C.

[Rare-earth fluorides;] Purification of precipitates [of —] D. Burns, Lakewood, Ohio, Assignor to National Carbon Co. U.S. Pat. 1,272,375, July 16, 1918. Date of appl., Sep. 19, 1914.

Precipitated fluorides of rare-earth metals containing also sulphates of rare-earth metals are mixed with sodium fluoride and calcined above 500° C. The sulphates are converted into soluble salts which may be removed by washing.—W. F. F.

Titanic oxide concentrate and method for obtaining the same. A. J. Rossi, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,272,855, July 16, 1918. Date of appl., Nov. 27, 1917.

To a solution of titanate sulphate are added an extract of vegetable matter and a sufficient quantity of a calcium compound nearly to neutralise the excess of sulphuric acid. The mixture is boiled and the precipitate separated and dehydrated.

—L. A. C.

Magnesium oxide; Process for obtaining — from dolomite, etc. A. M. Mitchell, Tuckahoe, N.Y., Assignor to Mitchell and Grenelle, Inc., New York. U.S. Pat. 1,273,110, July 16, 1918. Date of appl., Mar. 25, 1916.

Ground dolomite is subjected to a tumbling and grinding operation while being heated to about 1000° F. (about 540° C.). The crystalline calcium carbonate is then readily separated from the magnesium oxide which is formed. The magnesium oxide is again calcined at a temperature sufficient to expel any remaining carbon dioxide.

—L. A. C.

Salt manufacture. C. L. Weil, Port Huron, Mich. U.S. Pat. 1,273,208, July 23, 1918. Date of appl., Nov. 3, 1917.

Small crystals of salt are first produced by "flashing" the brine, which is then cooled in a closed space provided with disc evaporators so as to produce relatively large crystals of salt, and to build up the small crystals upon the larger ones. By regulating the rate of rotation of the discs during cooling, the proportions of large and small crystals in the product may be controlled.—T. H. B.

Nitrogen compounds from metal carbides; Process for the production of — V. Thrane, Christiania, Norway. U.S. Pat. 1,273,690, July 23, 1918. Date of appl., Nov. 10, 1916.

A layer of inert material is fed on to a moving conveyor, and a mass of metal carbide is fed on

to this layer. The moving mass is subjected to a current of nitrogen, and is heated to a temperature sufficient to start a chemical reaction between the nitrogen and the carbide. Once started, the exothermic reaction propagates itself through the mass.

—J. H. P.

Ammonia; Preparation of synthetic — C. Ellis, Montclair, N.J., Assignor to C. S. Lukins, Rye, N.Y. U.S. Pat. 1,273,772, July 23, 1918. Date of appl., May 13, 1916.

A mixture of nitrogen and hydrogen is passed through a catalytic agent comprising nickel-cobalt carbide.—J. H. P.

Carbon dioxide; Preparation of — from neutral or basic carbonates. J. Behrens, Bremen. Ger. Pat. 305,417, May 11, 1917.

Neutral or basic carbonates are heated with water to 150° C. or over in closed vessels. The gas evolved is released from time to time and cooled and dried.

—L. A. C.

Bleaching liquor; Preparation of dilute — from sodium carbonate solution and chlorine. Deutsche Solvay-Werke Act.-Ges., Bernburg. Ger. Pat. 306,193, Oct. 20, 1916.

A bleaching liquor ready for immediate use, in which between 1 and 2 mols. of combined chlorine are present per 1 mol. of sodium carbonate used, is prepared by passing the requisite amount of chlorine gas into a solution of sodium carbonate; by preparing two solutions in which 1 and 2 mols. of combined chlorine respectively are present per 1 mol. of sodium carbonate used and then mixing the two solutions; or by passing chlorine gas into a solution of sodium carbonate until 2 mols. of chlorine are combined per 1 mol. of sodium carbonate, and then adding the requisite amount of sodium carbonate.—L. A. C.

Potassium persulphate; Preparation of — by electrolysis. O. Neher & Co., and O. Nydegger, Mels, Switzerland. Ger. Pat. 306,194, Feb. 7, 1917. Under Int. Conv., Jan. 25, 1917.

Sodium and/or ammonium sulphate or bisulphate is added to the solution of potassium bisulphate used as electrolyte in the preparation of potassium persulphate, the yield thereby being increased 1½ to 2 fold, and a purer product being obtained.

—L. A. C.

Nitrogen and oxygen gases; Apparatus for the separation of — from liquid air. G. James, W. T. Vint, and H. Alexander, Leeds. Eng. Pat. 117,937, Aug. 3, 1917. (Appl. No. 11,256 of 1917.)

Inside a wooden casing are two superposed tanks, preferably of equal dimensions, connected by a number of vertical pipes. Above the upper tank, which is open, is a hood provided with a valved outlet pipe passing through the casing, so arranged that it can be lowered on to the tank. At the top and bottom of the casing are adjustable shutters, whereby the passage of air over the apparatus can be regulated. An inlet pipe passes into the upper tank, and from the bottom of the lower tank an outlet pipe, fitted with a valve, leads to a helical pipe, also enclosed in a casing, the latter being open at the bottom, and having on the top an adjustable lid. In order to work the apparatus, the upper shutters and the lid above the helical pipe are closed, the lower shutters being left open. The valve connecting the lower tank with the helical pipe and the valve over the hood are both closed, the hood being raised above the upper tank.

Liquid air is poured into the upper tank, and the vapours at first formed flow out of the top of the tank over the apparatus, displacing the warmer air in the casing, which escapes through the lower shutters. As soon as the liquid air ceases to vaporise, the valve connecting the lower tank with the helical pipe is opened, and as soon as the helical pipe has cooled down to the temperature of the liquid air the hood is lowered and the valve above it opened. On opening the upper shutters and the lid of the casing enclosing the helical coil, a downward current of air through the casings evaporates the liquid air in the apparatus, nitrogen gas at approximately -191°C . passing out through the valve above the hood and oxygen gas at approximately -183°C . at the upper end of the helical pipe. Two heat-interchangers, each consisting of a helical coil of pipe having a pipe of smaller diameter throughout its interior, may also be attached to the apparatus, one replacing the helical coil. Nitrogen gas at -191°C . and liquid oxygen at the same temperature are caused to pass upwards respectively through the inner tubes and air at ordinary temperature is forced into the upper end of the outer tube. Liquid carbon dioxide and oxygen are tapped off at the points at which the temperature reaches -90°C . and -183°C . respectively, and nitrogen gas at -191°C . issues from the lower end.—L. A. C.

Sulphur; Process for recovering —. A. F. Hoffman, Pittsburgh, Pa. U.S. Pat. 1,273,370, July 23, 1918. Date of appl., Apr. 8, 1916.

Pyritic ore is heated to drive off sulphur as sulphur dioxide, which is passed into a heated container where it is burned with a gaseous hydrocarbon to produce sulphur, carbon dioxide, and water. The container may be heated by open flame gas jets, and a catalyst, such as a mixture of calcium sulphide and sulphite, may be used.

—J. H. P.

Bleaching-powder; Manufacture of —. J. W. Moore, Runcorn, Assignor to Castner-Kellner Alkali Co., Ltd., London. U.S. Pat. 1,272,880, July 16, 1918. Date of appl., Feb. 5, 1918.

VIII.—GLASS; CERAMICS.

Optical glass; Special pots for melting —. A. V. Bleiningner. J. Amer. Ceram. Soc., 1918, 1, 15—24.

SATISFACTORY pots were made from a mixture of 25% of kaolin, 25% of plastic bond clays, 7% of

felspar, and 43% of "a calcine" made by firing a mixture of 80% of equal parts of North Carolina, Florida, and Georgia kaolins, 10% of flint, and 10% of felspar at cone 14. Waste bisque of white ware potteries using a body composed of kaolin 35%, ball clay 15%, felspar 14%, and flint 36% is an efficient substitute for the above-mentioned "calcine" if not too finely ground. The following mixture is used for hand-made glass pots at the U.S. Bureau of Standards: White ware bisque (through No. 10-mesh) 35%, grog from old glass pots (through 10-mesh) 10%, felspar 3%, flint 4%, Tennessee ball clay No. 5 15%, Illinois bond clay 5%, kaolin 28%. The materials are mixed and then tempered in a wet pan with the rollers $\frac{1}{4}$ in. above the pan so as to reduce grinding to a minimum. The paste is passed through a vertical pug-mill and stored as long as possible, but not less than one month. The pots are built up by hand in the usual manner and allowed to dry for about four weeks. For pots made by casting, the body consists of white ware bisque 48%, plastic bond clay 23%, kaolin 24%, felspar 5%, made into a slip containing 80% of solids by means of an aqueous solution of 0.20% (on the dry weight of the body) of a mixture of equal parts of sodium carbonate and sodium silicate. The core of the mould must be held firmly in position by means of cross beams and tie-rods. The slip is supplied to the mould through three funnels arranged symmetrically around the circumference. Absorption is complete after about 16 hrs., and the core may then be removed. The outer mould may be removed after 24 hrs. The cast pots may be dried easily in three weeks. Previous to use, a new pot should be vitrified by heating in the glass furnace to at least 1400°C .; the temperature is then lowered and the charge introduced. Unless this is done the pots are liable to corrode unduly. The rods used for stirring the molten glass are made of the same composition as the pots.—A. B. S.

Temperature control in glass-melting furnaces; Method of —. C. N. Fenner. Phys. Rev., 1918, 11, 141. J. Soc. Glass Tech., 1918, 2, Abs., 85.

THE use of platinum and platinum-rhodium thermo-elements introduced through the furnace walls proved unsatisfactory, probably owing to contamination of the thermo-elements by furnace gases. Good results have been obtained with a Leeds and Northrup optical pyrometer. In comparative tests at the temperatures (1300° — 1400°C .), at which the important operations of glass-making are performed, the optical pyrometer gave indications agreeing almost exactly with those furnished by a thermo-junction placed in a porcelain tube introduced into the furnace, thus showing that the radiation given out by the walls of the glass furnace corresponded with black-body radiation.

Alumina; Influence of — on the fusibility of glasses. F. Singer. Keram. Rundsch., 1917, 25, 142. J. Soc. Glass Tech., 1918, 2, Abs., 53—55.

IN continuation of previous work (this J., 1917, 873), the effect of adding increasing quantities of alumina (from 0.05 mol. to 0.2 mol. in steps of 0.05 mol.) to two glasses of the formulae $0.5\text{Na}_2\text{O}$, 0.5CaO , 3SiO_2 and $0.4\text{Na}_2\text{O}$, 0.6CaO , 3SiO_2 respectively was studied. In both cases the addition of alumina rendered the melts more fusible, the effect being marked even with only 0.05 mol. Al_2O_3 and increasing with the quantity of alumina added. The results were the same whether the alumina was added as aluminium hydroxide or as kaolin. A suitable source of alumina is pegmatite, which is comparatively cheap and also introduces some of the required alkali at the same time. Alumina

(0.15 mol.) was found also to increase the fusibility of a glass of the composition, $0.2\text{Na}_2\text{O}$, $0.3\text{K}_2\text{O}$, 0.1MgO , 0.2CaO , 0.1SrO , 0.1BaO , 3SiO_2 . It is probable that in the case of other types of glass also, e.g., lead crystal, borate, or phosphate glasses, the fusibility would be improved by addition of alumina, but the limiting quantities of alumina would vary with each particular type of glass. In the case of heavy lead glasses a small quantity of alumina considerably improves the resistant qualities of the glass without having any very marked effect on the fusibility.

Selenium as a decolorising agent [in glass]. W. Frommel. *Keram. Rundsch.*, 1917, 25, 95. *J. Soc. Glass Techn.*, 1918, 2, Abs., 51—52.

GLASSES decolorised by means of selenium are more brilliant than similar glasses decolorised by means of manganese or nickel oxides, but acquire a brownish tinge on prolonged exposure to bright sunlight. The decolorising action is due to the presence of minute particles of selenium which tend to give a red colour to the glass and thus neutralise the faint green coloration due to iron. Selenium is readily oxidised, and hence can be used with advantage only in the absence of oxidising agents (nitre, etc.); preferably arsenic trioxide is added as a reducing agent. When sodium selenite is used, this is decomposed with liberation of selenium dioxide, and the latter is reduced to selenium either by the arsenic trioxide or by the furnace gases. The colouring effect of 1 kilo. of iron oxide can be neutralised by 0.208 gm. of selenium. For ordinary glass of good quality 0.1 gm. of selenium or 0.2 gm. of sodium selenite may be used for 250 kilos. of glass. The portion of the glass batch containing the selenium should be added to the pot at the second filling on. Glass decolorised by selenium may usually be recognised by its brilliance and by the reddish tinge it acquires on prolonged heating.

Glass; Structure and properties of —. G. Quincke. *Ann. Physik*, 1915, 46, 1025. *J. Soc. Glass Techn.*, 1918, 2, Abs., 61—62.

THE author applies his "foam wall" theory of the structure of solids (compare this *J.*, 1905, 1259; 1906, 932) to explain the physical and mechanical properties of glass. It is considered that during the cooling of glass there separate, at short intervals, thin invisible layers of very viscous, oily liquids, rich in silicic acid. These liquids each contain several allotropic modifications of silicic acid, the concentrations varying in the different layers. In consequence of surface tension effects at the boundaries between the different layers, "foam cells" enclosed by "foam walls" are produced, and the properties of the glass depend largely upon the character (size and shape) of the "foam walls" and the number of such "foam walls" in unit volume.

Ceramic ware; Effect of gravitation upon the drying of —. E. W. Washburn. *J. Amer. Ceram. Soc.*, 1918, 1, 25—34.

A PIECE of moist clay weighing 10 grms. and containing 30% of water was suspended by a wire in a stoppered bottle containing a little water, the clay being about 6 cm. above the water. When kept at a constant temperature the clay gradually lost water, at the rate of about 30 mgrms. per day, during eleven days. The clay was then lowered so as to be at the same level as water contained in an annular vessel inside the bottle. The clay then increased in weight. The author suggests that in the first part of the experiment the water distilled out of the clay under the influence of gravitation, and that it returned to the clay in the second experiment. It is concluded that in order to keep clay

moist by enclosing it in a chamber containing a vessel of water, the latter should not be at a lower level than the clay. Cloths hung around the sides of the chamber with their lower ends in a vessel of water and kept wet by capillary action will not prevent the drying of the clay by gravitation (as in the first experiment), as the water held up by capillary force is under tension and therefore at a low vapour pressure, which is identical with that at the surface of the water in the vessel. The behaviour of the clay is analogous to that of a gel which has been soaked in water until swelling has reached a maximum (Schroeder: *Proc. Amsterdam Acad.* 1913, 15, 1078; 1914, 17, 92). In such cases Wolff and Buchner (*Z. physik. Chem.* 1912, 89, 271) found that when precautions were taken to prevent the action of gravitation acting differently on the gel and the water, no drying occurred. If the rate of drying is determined by the difference, Δp , between the vapour pressure of the water in the clay and the partial pressure of water in the surrounding air at the height, h , above the surface of the water, and if D is the density of saturated water vapour at the temperature of the clay and water, and g the acceleration due to gravity, $\Delta p = gDh$. The rate of drying by gravity would then vary, as the temperature and a gravity dryer filled with saturated steam at 100°C . would dry more rapidly than the same dryer at 0°C . Hence, the rate of drying in a gravity dryer is determined by the vapour pressure gradient and not by the dryness of the air in the dryer, and, therefore, the more moisture there is in the air of the dryer the more rapid will be the drying.

In the discussion, A. S. Watts pointed out that potters keep clay cups moist indefinitely in a chamber with a bucket of water at the bottom, which appears to contradict the author's conclusions, but suggested that there might be a circulation of air in the potter's cupboard owing to the temperature not being kept uniform as in the author's experiments. Linbarger stated that he had found that there is more evaporation in a dryer with a relative humidity of 90% than when the humidity is 65%—a paradox which may possibly be explained by the action of gravity.—A. B. S.

Kiln; Test of a producer gas-fired periodic —. C. B. Harrop. *J. Amer. Ceram. Soc.*, 1918, 1, 35—64.

THE kiln was fired by means of a gas-producer of the round pressure type, 10 ft. 6 in. diam., with a double system of blast pipes delivering steam and air to both the bosh and the centre tuyère. The maximum rate of gasification was 1250 lb. of coal per hr., steam at 25 lb. gauge pressure being supplied at the blower. The gas had a water-gauge pressure of 0.14 in. and an average temperature of 580°C . The fuel used was an Indiana "nut" coal charged at intervals of 25 mins. Air for combustion of the gas was supplied by a No. 9 centrifugal blower through a 12 in. pipe which encircled the kiln near the top of the wall, with 4 in. pipes leading to the burners. The air pressure was 0.95 in. water gauge. The kiln was a typical one of the round downdraught type, 30 ft. diam., with 8 furnaces and a perforated floor. An Underwood's patent gas-burner was fitted to each furnace. The heating was started with four burners for 12 hrs., after which the remaining burners were lighted. For the first 12 hrs. a brick was laid across each 4 in. \times 15 in. opening above the top of the hob in each furnace; 18 hrs. after starting two bricks were laid across these openings; after 30 hrs. the openings were blocked up completely. The burning was completed in $95\frac{1}{2}$ hrs., a temperature of 995°C . being first attained, after which it was slowly increased during 24 hrs. The

contents of the kiln consisted of 9522 common and 62,184 facing bricks made by the stiff plastic process and weighing just under $5\frac{1}{2}$ lb. each; they were set in the usual manner in 2-brick benches. The bricks settled 11 in. in a total height of 14 ft., the gas being shut off as soon as this amount of settlement was reached. The heat expenditure and losses were: In producer and flues, 13.2%; in flue gases, 28.8%; in moisture and waste gases, 0.3%; consumed in dehydration of clay, 2.2%; in ware at end of burning, 20.6%; in kiln structure above ground level at end of burning, 6.3%; in kiln bottom at end of burning and loss by radiation and convection, 28.6%, of which only about 15% was due to radiation and convection. The coal consumption averaged 989 lb. per 1000 bricks. Owing to the loss of heat in the producer and flues, the use of producer gas is less efficient than the direct combustion of coal, but advantages are gained through the centralisation of coal and ash, the greater cleanliness of the yard, the reduced space required for the kilns, the greater control of the combustion, the more rapid burning and the saving in labour when more than one burner is employed. Either oxidising or reducing conditions to any degree can be obtained as desired, and the change from one to the other may be made rapidly. The producer gas has a lower flame temperature than coal burned direct, but temperatures up to 1150°C . and possibly higher may readily be obtained.—A. B. S.

Refractory bricks; Testing and inspection of — C. E. Nesbitt and M. L. Bell. Amer. Soc. for Testing Materials, June, 1918. Blast Furnace and Steel Plant, 1918, 6, 341–345. (See also this J., 1917, 1048, 1049.)

Tests should be made during manufacture to ensure uniformity in grinding, drying, and burning. Silica bricks are not usually subjected to slugs, and for them a spalling and a hot crushing test are sufficient, but fireclay bricks should also be subjected to slag penetration tests. The authors do not favour the hot crushing test for fireclay bricks, but prefer the load or ball impression test. In addition, all bricks should be carefully inspected, and cracked, warped, poorly moulded, off-sized, and badly burned bricks should be eliminated. Serious lack of uniformity in the products of a single works is shown by the great variations in the results of spalling and crushing tests of individual or successive deliveries. The present methods of manufacture do not produce a uniform product, and specifications should, therefore, be used by purchasers.—A. B. S.

Baryta glazes; Experiments on — H. Fritz. Sprechsaal, 1918, 51, 51. Z. angew. Chem., 1918, 31, Ref., 239.

MIXTURES of baryta and quartz, or baryta, alumina, and quartz, do not melt at Seger cone 4a–6a (1160° – 1200°C). The addition of felspar causes superficial sintering, but not fusion. On addition of zinc in the presence of at least 0.6BaO, and an "acidity" not less than $0.1\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$, good glazes are formed at this temperature; these have a pale blue tint which produces a good white on a stoneware body, and may render the use of cobalt unnecessary.—A. B. S.

Zinc sulphide; Use of — in white and luminous enamels. J. Schaefer. Keram. Rundsch., 1917, 28, 75. J. Soc. Glass Techn., 1918, 2, Abs., 50.

Zinc sulphide may be used with excellent results as an opacifying agent in enamels for sheet iron, provided metallic oxides capable of decomposing it are not present. The opacity, which is due to the sulphide as such and not to zinc oxide produced by oxidation, is equal to that obtained with tin

oxide, but the zinc sulphide enamels have not the whiteness and brilliancy of tin enamels. Zinc sulphide should not be used in coloured enamels or in those containing oxides of lead, arsenic, antimony, or bismuth. Enamels in which luminous zinc sulphide has been used remain unaltered or with only a very slight loss of luminosity for years.

PATENTS.

Glass for absorbing ultra-violet radiations; Manufacture of — R. Haddan, London. From Corning Glass Works, Corning, N.Y., U.S.A. Eng. Pats. (A) 118,397 and (B) 118,398, Apr. 15, 1918. (Appl. Nos. 6398 and 6399 of 1918.)

A GLASS for absorbing ultra-violet rays is made by adding to an ordinary lime, barium, lead, or zinc glass batch: (A) at least 6% of titanium dioxide, an oxidising salt (nitre) in sufficient quantity to prevent the reduction of the TiO_2 , with or without cerium oxide and/or vanadium oxide; or (B) at least 1% of a higher oxide of vanadium than V_2O_5 , with or without an oxidising agent (nitre) and a complementary, but absorptively inert substance (MnO_2 , CoO , NiO , UO_2) to change the hue of the glass from green to amber. Titanium dioxide is about half as effective as cerium oxide. A lime-soda glass containing 7.7% TiO_2 and 7.7% $\text{Ce}(\text{NO}_3)_3$ is brilliantly clear yellow, and in plates 2 mm. thick completely cuts off the 0.365 ultra-violet line. A glass containing both $\text{Ce}(\text{NO}_3)_3$ and TiO_2 has a more brilliant colour and greater desirable absorption than a glass containing one of these substances superimposed on a glass containing the other. The addition of borax to the glass batch increases the refractive index of the glasses containing TiO_2 . Reduction of higher vanadium oxides to V_2O_5 must be prevented, as the latter does not cut off the ultra-violet rays. A large proportion of borax in the glass containing vanadium makes the colour muddy. A glass containing 1% vanadium oxide completely cuts off the ultra-violet 0.365 line in plates of 4 mm. thickness, and if 2% of vanadium oxide is used the same cut-off is effected in plates 2 mm. thick.—A. B. S.

Lehr. W. L. Clause, Assignor to Pittsburgh Plate Glass Co., Pittsburgh, Pa. U.S. Pat. 1,268,217, June 14, 1918. Date of appl., June 15, 1912.

A GLASS-ANNEALING *lehr* has a bottom wall supported above the ground by several vertical walls spaced apart to permit the passage of air between them. Conduits for heating gases are provided beneath the bottom wall for heating the *lehr* and a heat-storing arrangement beneath these conduits, with its thickest part adjacent to the front end of the *lehr* and gradually diminishing in thickness to the other end. Cold air may also be passed through conduits beneath the heat storage element.

Glass; Method of making coloured — H. T. Bellamy, Chicago, Ill. Assignor to Western Electric Co., Inc., New York. U.S. Pat. 1,271,652, July 9, 1918. Date of appl., Feb. 5, 1917.

A BATCH of sand, red lead, sodium nitrate, antimony oxide, borax, tin oxide, potash, lime, and gold in suitable proportions is heated to 2400°F . (1315°C .), cooled, and then reheated until plastic.

—A. B. S.

Gas and air mixer for glass furnaces. E. Majot, Maumee, Ohio. U.S. Pat. 1,273,171, July 23, 1918. Date of appl., Aug. 28, 1917.

A COMBINED mixer and heater for a glass furnace consists of two flues—the upper one for hot air and the other for producer gas—with outlets in a vertical plane and a third hot air flue, with a horizontal

outlet close to the lower outlets of the other two flues, and with a shutter for regulating the amount of air passed through this flue.—A. B. S.

Dryer [for bricks]. C. H. Klein, Chaska, Minn. U.S. Pat. 1,272,676, July 16, 1918. Date of appl., Sep. 17, 1917.

A DRYING chamber is provided with doors at the ends for the introduction of trucks. Each truck carries a number of superimposed trays, fitting closely against the side walls of the chamber, and adapted to hold pallets of bricks spaced apart. Hot air or gas, entering the chamber under pressure just above the lowest tray, travels to an outlet at the top by passing from side to side of the chamber across each tray in succession, the spaces between consecutive trays being in communication by means of ducts alternately in one or other of the two side walls. Other ducts in these walls enable the moist gases to be reinforced by introduction of fresh dry gases at certain stages in their travel.—J. H. L.

Refractory ceramic article and method of making the same. A. W. Oliver, Assignor to Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,273,529, July 23, 1918. Date of appl., Feb. 16, 1918.

PLASTIC clay, a refractory material (e.g., carborundum and graphite), water, and tar are mixed until a high degree of plasticity is developed and the mixture is then moulded into the desired form.

—A. B. S.

Muffle kiln; Tunnel — for ceramic products. A. Krautzberger, Wistritz, Bohemia. Ger. Pat. 306,055, May 17, 1917.

ONE or more externally heated muffles are built at the side of the tunnel. The goods to be heated are placed on cars and pass along the tunnel in the usual manner until they reach one of these muffles, when (by means of an opening opposite the muffle) they are pushed into the latter and remain there until they attain the desired maximum temperature. They are then drawn back on to the cars, are gradually taken through the remainder of the tunnel, and finally pass out of the kiln. The goods only remain in the side muffle for about 10 mins., so that the operation of the kiln is practically continuous. If each part of the tunnel in front of and behind the muffle holds six cars, the goods pass completely through the kiln in 2 hrs.—A. B. S.

Glass; Apparatus for manufacture of sheet —. T. J. McCoy, Shinglehouse, Pa., U.S.A. Eng. Pat. 117,194, Oct. 29, 1917. (Appl. No. 15,735 of 1917).

Cane-glass manufacture. Manufacture of glass rods and tubes. J. T. Fagan, Cleveland, Ohio, Assignor to General Electric Co. U.S. Pats. 1,273,345 and 1,273,346, July 23, 1918. Dates of appl., June 3, 1913, and July 20, 1916.

SEE Eng. Pat. 17,602 of 1913; this J., 1914, 831.

IX.—BUILDING MATERIALS.

Anhydrite and dead-burned gypsum; Hydration of —. A. C. Gill. J. Amer. Ceram. Soc., 1918, 1, 65—71.

IN a wide-mouthed 250 c.c. bottle with a metallic screw cap, but no rubber washer, was placed 50—60 grms. of anhydrite crushed small enough to pass through an 8-mesh sieve. A second similar bottle was charged with several lumps of alabaster which

had been heated for $3\frac{1}{2}$ hrs. to 560°C ., the lumps being 1 in. or more in diameter, and having an aggregate volume of 60—75 c.c. Both bottles were filled with water and closed on Oct. 28, 1911. Late in 1917 it was found that all the water had evaporated, and that in the first bottle the small fragments of anhydrite were so firmly united by gypsum crystals that they could not be removed without crushing them. Glistening crystals of gypsum were seen in the interstices, and brilliant acicular crystals attaining a maximum length of $\frac{1}{4}$ in. projected into the free space which had been occupied by the water. About 34% of the original anhydrite had been hydrated into gypsum. The pieces of burned alabaster in the second bottle were covered completely with fine bristling gypsum needles about $\frac{1}{4}$ in. long, and the inner portion of the mass had set harder than ordinary plaster of Paris. About 87% of the calcium sulphate had been rehydrated, this hydration having been effected much more readily than in the case of anhydrite.—A. B. S.

PATENT.

Artificial stone; Process of making —. P. M. Sharples, West Chester, Pa., Assignor to White Heat Products Co., Plainbrook, Pa. U.S. Pat. 1,273,547, July 23, 1918. Date of appl., Feb. 2, 1918.

ARTIFICIAL stone is made by mixing calcined sand with disintegrated glass, and forming, pressing, and heating the mixture until the glass fuses.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Reaction between pure carbon monoxide and pure electrolytic — below the A1 inversion. H. C. H. Carpenter and C. C. Smith. Iron and Steel Inst., Sep. 1918. [Advance copy.] 53 pages.

WHEN electrolytic iron is heated at 650°C . in an atmosphere of carbon monoxide, a substance believed to be Fe_3C is formed: $3\text{Fe} + 2\text{CO} = \text{Fe}_3\text{C} + \text{CO}_2$, the reaction probably being facilitated by a preliminary dissociation of the carbon monoxide. It is possible that the stable condition at 650°C . is iron and graphite, the carbide formed being an intermediate metastable product. The presence of sufficient carbon dioxide in the carbon monoxide prevents the formation of the carbide, while hydrogen facilitates it.—F. C. Th.

Iron-carbon alloys; Formation of graphite in —. J. E. Hurst. Engineering, 1918, 106, 217—218.

A CONSIDERATION of the various iron-carbon diagrams suggested leads to the conclusion that graphite does not separate out directly from the liquid, but is formed as a result of decomposition of a previously separated carbide. The Upton thermal-equilibrium diagram (this J., 1908, 1114) is considered to possess a considerable amount of truth. The author considers that in cast iron graphite is precipitated from the austenite and not from the cementite. On reheating grey cast iron to 900°C . part of the graphite is re-absorbed, forming austenite, without any visible intermediary formation of carbide. In grey cast irons containing ferrite the latter is deposited after the graphite and around it.—F. C. Th.

Steel; Influence of hot-deformation on the qualities of —. G. Charpy. Iron and Steel Inst., Sep., 1918. [Advance copy.] 19 pages. (See also this J., 1918, 469 A.)

FORGING under the hammer or press results in very marked differences in the extension

produced at different points. The effects of such treatment are exceedingly irregular, especially towards the ends of the bars. Rolling produces practically regular deformation throughout the whole length of the billet. Results are given which indicate that the effect of hot working is to produce deterioration in the test-bars cut transversely, and the progressive distortion of the primary dendritic structure as the working is increased is shown. The influence of the direction of the rolling, and hence of these dendrites upon the resistance to impact, is shown by the following results. When the notch was perpendicular to the direction of rolling, the impact value of a certain steel was 13.5 kilogrammetres; when notched at an angle of 45°, 3.4; at an angle of 20°, 1.5; and parallel to the direction of rolling, 1.3.—F. C. Th.

Steels; Slow contraction of hardened carbon —. T. Matsushita. Sci. Rep. Tohoku Imp. Univ., 1918, 7, 43—52.

AFTER being quenched, hardened steel is in a highly strained state, the strain subsequently undergoing gradual relief with concurrent generation of heat and contraction (compare Brush and Hadfield, this J., 1917, 505). In well hardened steels the gradual contraction is always observed, but in imperfectly hardened specimens there is a gradual elongation often associated with a subsequent contraction. This effect is attributed to an incomplete A1 transformation by the moderately rapid cooling, the subsequent gradual conversion of austenitic structure to pearlitic being accompanied by an expansion; the contraction is due to the gradual separation of an unstable cementite; if the temperature be raised to 100° C. this separation is greatly accelerated, occupying less than 2 hours, and no subsequent contraction is then observable. The separation of the unstable cementite does not appreciably affect the hardness of the steel, but the separation of the more stable cementite (which is possible at 340° C.) is accompanied by a loss of hardness. Quenching causes a considerable increase in the electrical resistance of steel by increasing the amount of cementite in solid solution, whilst tempering has the reverse effect. The evolution of heat which invariably accompanies the gradual elongation or contraction of quenched steel arises from the heat of transformation, and is not due merely to the yielding strain as was formerly supposed.—D. F. T.

Hardened steel; Rate of change at 100° C. and at ordinary temperatures in the electrical resistance of —. E. D. Campbell. Iron and Steel Inst., Sep., 1918. [Advance copy.] 6 pages.

THE rate of change of electrical resistance of four steels containing from 0.57 to 1.05% C. and hardened from 900° C., was determined at ordinary temperatures and at 100° C. A selection of the results (microhms per cm. cube) is given in the following table:—

Treatment	Carbon, per cent.			
	0.57	0.76	0.95	1.05
Quenched from 907° C.	21.88	32.24	36.32	39.73
Tempered 1 hr. at 100° C.	20.67	27.47	29.62	32.97
Tempered 12 hrs. at 100° C.	19.87	25.75	27.31	29.19
After standing at 25° C.:				
For 7 days	21.17	32.48	38.53	39.87
For 24 months ..	20.60	30.33	32.53	36.47

—F. C. Th.

Nickel steels; Thermal and electric conductivities of —. K. Honda. Sci. Rep. Tohoku Imp. Univ., 1918, 7, 59—66.

AN investigation of the thermal and electric conductivities (compare Honda and Simidu, this J., 1918, 125 A) of a complete series of nickel-iron alloys made by fusing commercial nickel with various proportions of low-carbon steel. The curves for the two conductivities follow similar courses, each reaching a marked minimum at 70% Fe and 30% Ni; the ratio of the two conductivities is not constant, but the variation is not great. Specimens once cooled in liquid air show a small maximum and minimum in each curve at 21% and 27% Ni respectively, the curves then declining to the marked minimum already mentioned; specimens once heated to 900° C. do not exhibit a secondary maximum, a slight inflexion forming the only irregularity. Experiments were also made as to the intensity of magnetisation with these alloys.

—D. F. T.

Hardness [of metals]; Relation between ball hardness and scleroscope —. A. F. Shore. Iron and Steel Inst., Sep., 1918. [Advance copy.] 20 pages.

UNDER normal conditions of testing it has not been found possible to obtain a satisfactory curve for converting Brinell to scleroscope hardness numbers. If the load to produce a constant indent of 1 mm. diameter is used as a measure of ball hardness, a smooth curve is obtained when this value is plotted against the scleroscope value:—30 on the scleroscope scale then corresponds to 90 tons per sq. in., 60 to 212 tons, 90 to 425 tons. The substitution of a diamond ball under a load of 750 kilos. for the usual hardened steel ball results in much more consistent values being obtained for very hard steels. It is claimed that the scleroscope measures a value closely connected with the elastic limit, the Brinell number being more nearly allied to the maximum stress. By using a small load (750 kilos.) the agreement between the two tests becomes much closer; a load of 3000 kilos. is considered to be far too great.

R. Hadfield, in an appendix, strongly recommends the operation of the Brinell test with variable load so as to give the same size depression (1 mm. diameter), and gives curves and tables showing the relationship of hardness to tensile and compression properties.—F. C. Th.

Iron alloys; Magnetic analysis as a means of studying the structure of —. K. Honda. Iron and Steel Inst., Sep., 1918. [Advance copy.] 43 pages.

MAGNETIC analysis is practically free from any time lag, and indicates the existence of critical points in steel at 790° C., 900°—910° C., and 1410°—1420° C., in cobalt at 1150° C., in nickel at 280° C., in cementite at 215° C., in the double carbide of iron and tungsten (see this J., 1918, 421 A) at 400° C., and in magnetite at 580° or 680° C. These changes allow changes in the structure of steel at high temperatures to be investigated. Thus cementite heated to 800° C. or higher partially decomposes and gives free iron, which, with undecomposed carbide, gives the A1 point. About 90% of the Fe₃C is thus decomposed. The double carbide of iron and tungsten is completely decomposed at 850° C. A very full examination of the tungsten steels is given.

—F. C. Th.

Zirconium in ferrozirconium and steel; Determination of —. J. D. Ferguson. Eng. and Min. J., 1918, 106, 356.

ONE grm. of ferrozirconium (or 3 grms. of steel) is dissolved in 25 c.c. of a mixture of 10 c.c. of water,

5 c.c. of nitric acid, and 5 c.c. of hydrochloric acid, and evaporated to dryness. The residue is heated with 1 c.c. of concentrated sulphuric acid and 30 c.c. of water and the silica filtered off and washed successively with boiling water, with 1 c.c. of sulphuric acid diluted with 20 c.c. of water, and again with boiling water. If a residue remains after fuming off the silica with hydrofluoric acid, it is fused with an excess of sodium carbonate, extracted with hot water, and the insoluble sodium zirconate fused with potassium bisulphate. The solution of this fusion is added to the main filtrate from the silica. The combined filtrate is diluted to 400 c.c., heated to boiling, and 6 grms. of sodium thiosulphate for each grm. of alloy is added, with constant stirring. The addition of 1 grm. of sodium phosphate in solution precipitates zirconium as a greenish precipitate, and after standing on a hot plate the precipitate is filtered off without suction, and washed. The precipitate is ignited, and weighed as zirconium phosphate. Iron should be reduced to the ferrous condition, and the solution before precipitation should contain approximately 1% of sulphuric acid. If titanium is present, as noted by the pink colour of the zirconia precipitate, the latter is fused first with sodium carbonate and then with potassium bisulphate as above, and the 1% acid solution is treated with hydrogen peroxide to oxidise the titanium, and the zirconia precipitated as phosphate as described.—C. A. K.

Copper: Effect of cold work upon the tensile properties of pure —. W. E. Alkins. Inst. of Metals, Sep., 1918. [Advance copy.] 14 pages.

A HOT-ROLLED bar of copper, $\frac{7}{8}$ in. in diameter, was cold drawn to 0.04 in., the maximum stress being determined during the process. This increased from 15 to 31 tons, a break in the curve occurring at 23 tons per sq. in., corresponding to a diameter of about 0.35 in. It is suggested that the break is due to an allotropic change.—F. C. Th.

Copper-zinc alloys: an investigation of some of their mechanical properties. F. Johnson. Inst. of Metals, Sep., 1918. [Advance copy.] 9 pages.

THE test-pieces were cast in a horizontal mould producing castings 6 in. long by $\frac{3}{4}$ in. square. It was found that the Brinell hardness was uniform from 95 to 70% Cu; no decided maximum was found. The hardness curve of annealed alloys rich in zinc showed slight irregularities at 5% and at 15% Cu, but no sudden fall followed by a sharp rise. Alloys consisting wholly of the β solid solution were stronger than those containing excess of either α or γ ; the β solution containing 53% Cu possessed an ultimate tensile stress of 30.4 tons per sq. in. and an elongation of 37.5%, i.e., properties superior to those hitherto observed.—W. R. S.

Phosphorus in bronzes: Rapid method of estimating —. T. E. Rooney. Inst. of Metals, Sep., 1918. [Advance copy.] 2 pages.

DRILLINGS of the sample (0.5–2 grms.) are digested with 10 c.c. of strong hydrochloric and 20 c.c. of strong, or, if preferred, 60 c.c. of dilute, nitric acid (sp. gr. 1.135). The digestion must be sufficiently long to oxidise the whole of the phosphorus, but actual boiling and prolonged heating would cause precipitation of tin, which is difficult to re-dissolve. The liquid is diluted, if necessary, to 70 c.c., cooled, and 40 c.c. of ammonia (sp. gr. 0.96) added slowly with constant stirring, followed by 35 c.c. of molybdate mixture. The liquid is shaken for a few minutes, allowed to stand for 1–2 hours, and filtered preferably through a pulp filter. The precipitate is washed with water until free from acid, returned to the flask, and dissolved in N/20 caustic

soda; the excess of the latter is titrated with N/20 sulphuric acid in presence of phenolphthalein; 1 c.c. N/20 NaOH = 0.00337% P on 2 grms.—W. R. S.

Gun-metal: Influence of impurities on the mechanical properties of Admiralty —. F. Johnson. Inst. of Metals, Sep., 1918. [Advance copy.] 12 pages.

AFTER summing up the published statements on the influence of impurities on gun-metal, the author describes mechanical tests made with synthetic test-pieces ($\frac{1}{2} \times 4 \times 3$ in.), both chill-cast and annealed. The work was undertaken with the object of ascertaining which element or elements showed promise of utility in the manufacture of gun-metal castings, and which were detrimental. Tentatively the following conclusions, some of which are at variance with those submitted by other observers, are submitted in tabular form:

Impurity (not exceeding 1%)	Effect on mechanical properties	Effect on fluidity and surface appearance of chill castings
Al	Hardening and embrittlement	Good
Si	Inappreciable	Bad
Mn	"	Good
As	"	Inappreciable
Sb	"	Bad
Fe	Strengthening without loss of ductility	Bad
Ni	Toughening; increase of ductility	Inappreciable

—W. R. S.

Copper-aluminium alloy: A case of disintegration of a —. R. Seligman and P. Williams. Inst. of Metals, Sep., 1918. [Advance copy.] 3 pages.

A NUMBER of wire frames forming part of a consignment of scrap aluminium wire netting received for re-melting showed unusual signs of disintegration; the surface of the wire was broken up into loosely adhering, elongated grains uniformly inclined to the axes of the wires. The solid core remaining after removal of the loose grains contained Si 0.33, Fe 0.30, and Cu 2.65%; the copper content of the grains was 2.49%. The bulk of the material was found to contain Si 0.24, Fe 0.22, and Cu 0.07%. The disintegrated wire had apparently been severely overdrawn, for the core broke readily when bent at right angles; on annealing its ductility was restored, showing that the brittleness was not due to disintegration.—W. R. S.

Aluminium sheet: Annealing of cold-rolled —. R. J. Anderson. Inst. of Metals, Oct. 11, 1918. [Advance copy.] 18 pages. (See also this J., 1918, 245 A, 424 A.)

FULL annealing of cold-rolled aluminium sheet sufficient for draw-press requirements (i.e., Shore hardness 5 for the annealed metal) can be effected in 1 hour at 370°C. and in 10 minutes at 400°C. The temperature necessary falls as the amount of reduction in rolling is increased. Blistering of the sheets during the annealing is no worse with short heating at 400°C. than with long ones at lower temperatures, and is not affected by the oxidising atmosphere of the furnace. Short annealing at a higher temperature, besides being more economical, resulted in a smaller percentage of defectives in the subsequent drawing.—F. C. Th.

Tungsten: Metallography of —. Z. Jeffries. Engineering, 1918, 106, 239–242, 269–275, 300–302.

UNLIKE the majority of metals tungsten in which the crystals are drawn out by cold work, giving a fibrous fracture, is ductile and pliable. When, however, as a result of heating, recrystallisation occurs, the metal is extremely brittle and fragile at the

ordinary temperatures. Ductile tungsten is produced as follows. Tungstic oxide produced from the ore by fusion, lixiviation, and acidification of the solution, is dried and after the addition of 0.75% of thoria made into a paste with thorium nitrate solution. The mixture is dried and heated to 1100° C. for at least an hour to coarsen the particles. The fired oxide is then reduced in hydrogen at 1000° C. The coarse powder produced is compressed, baked in hydrogen at 1300° C., and then electrically sintered at 3000° C. for 10–15 mins. The resulting ingot has sp. gr. 18. The working of the metal is done in a swaging machine with high-speed steel dies. Before this treatment it is electrically heated to 1600° C. in hydrogen and reheated from time to time. Four or five dies are used to form a round rod. As the degree of work on the rod increases, the reheating temperature is lowered gradually to 1300° C., or for wires of less than 0.03 in. diameter to 1100° C. High-speed rolls may be substituted for the swaging dies. The sintered ingot, which is brittle as glass, consists of equiaxed crystals, which are drawn out during working, and the resulting wire can be bent or drawn cold. The tensile strength of the sintered ingot is 18,000 lb. per sq. in. and that of the 0.03 in. swaged wire 215,000 lb., with an elongation of 4% on 2 in. and a reduction of area of 28%. Wires less than 0.03 in. are hot drawn through diamonds; the smallest wires are the strongest. The tensile strength of a wire 0.00114 in. diameter is 590,000 lb. per sq. in., with a reduction of area of 65%. Reheating ductile tungsten to the recrystallisation temperature causes the loss of its ductility, this metal thus behaving in exactly the opposite way from others. Molybdenum acts like tungsten in that it is more ductile in its "coldworked" condition than in the equiaxed state. Tantalum when very pure and melted *in vacuo* is one of the most malleable and ductile of metals, and when annealed *in vacuo* at 1600° C. for 5 mins., the drawn wire recrystallises, becoming, unlike tungsten, much more ductile. When annealed in hydrogen at 1600° C., tantalum becomes very brittle. The effect of thoria on the sintered tungsten ingot is to decrease the grain growth at high temperatures, thus rendering the tungsten capable of being worked hot. More than 2% of thoria renders tungsten difficult to work into fine wires, since the crystals in the sintered ingot are relatively very large; 5% of thoria, however, again gives a finely crystalline structure. Tungsten very readily shows the excessively coarse structure found locally in annealed coldworked iron. With 2.5% of thoria the temperature of coarse grain growth is 3200° C., with 1.5% it is 2900° C., and with 0.75% 2600° C. The finest structure is obtained by reheating the tungsten to just above these "germinative" temperatures, the time required increasing as the temperature becomes lower, e.g., 12 mins. at 3200° C. or 30 mins. at 2600° C. In the presence of carbon at high temperature, W₂C is formed around the crystals, rendering the metal very brittle. With 0.75% of thoria, the amount generally used, a grain size of 6000 per sq. mm. is aimed at. A fine-grained metal is very hard. The lower the temperature of working the tungsten, the more ductile will it be. The recrystallisation temperature after cold work is 1300° C. for a 99.99% reduction, 1500° C. for 90%, and 2200° C. for 24%, whence the necessity for the working at progressively lower temperatures as the wire becomes finer.—F. C. Th.

Lead-bismuth-silver and lead-gold-silver alloys.
M. Goto. J. Coll. Eng., Imp. Univ., Tokyo. 1918, 9, 63–114.

In the presence of bismuth it is more difficult to concentrate by Pattinson's process the silver in

silver-lead alloys. The mother liquor contains much of the bismuth. A ternary eutectic is present, but no compound is formed. In the silver-gold-lead alloys rich in lead, this metal first separates out, the solution becoming richer in gold and silver. A eutectic of lead and a solid solution of gold and silver then freezes until the residue contains no silver. The mother liquor then contains 15% Au and freezes finally at 208° C. (See further J. Chem. Soc., Oct., 1918.)—F. C. Th.

Non-ferrous metals; Rapid recrystallisation in deformed —. D. Hanson. Inst. of Metals, Sep., 1918. [Advance copy.] 5 pages.

A BROKEN, tapered, tensile test-piece of aluminium was annealed for 30 mins. at 480° C. In the neighbourhood of the shoulder, where the strain was least, remarkably coarse crystals were developed. At 450° C. a less coarse recrystallisation resulted after 5 mins. reheating. Magnesium, zinc, lead, and copper gave similar results. An alloy of aluminium with 3% Cu and 20% Zn annealed for 5 mins. at 450° C. also gave a well-marked coarse grain between fine-grained regions. A 70/30 brass annealed at 800° C. for 5 mins. showed signs of a similar critical growth but less well marked.

—F. C. Th.

Solder without tin. C. W. Hill. Chem. and Met. Eng., 1918, 19, 170.

OF the lead-cadmium alloys that containing 8 to 9% Cd is the strongest, its freezing range extending from 275° to 248° C. The best flux is a mixture of fused chlorides in the following proportions: Sodium chloride 11%, potassium chloride 14%, zinc chloride 65%, ammonium chloride 10%. The solder will not flow well on copper, and must be maintained at a very even temperature not more than 30° C. above its melting point. The addition of tin, unless in considerable quantities, does not appreciably improve this solder. The addition of 5% of zinc to the cadmium-lead solder with 8.5% Cd gives excellent results applicable to a wide variety of work.—F. C. Th.

Metals; Resistance of — to penetration under impact. C. A. Edwards. Inst. of Metals, Sep., 1918. [Advance copy.] 28 pages.

THE diameter (d) of the indent made by a 10 mm. ball striking the sample with energy of 63 in.-lb. is related to the Brinell hardness number (H) by the equation $H = \frac{7455}{d^3}$. Further if ϵ is the energy of im-

pact the formula $d = c \sqrt[3]{\epsilon}$, where c is a constant for each metal, is approximately true especially for the harder metals and alloys. Experiments are recorded with balls and cones on lead, tin, aluminium, copper and iron which partly confirm the conclusion of Martel (Commission des Methodes d'Essai des Mat. de Construction, 1895, 3, Sect. A (Métaux), 261–277) that given a constant energy of impact then for each metal the volume of metal displaced is independent of the shape of the striker. There appears, however, to be some other as yet unknown factor involved. Metals such as tin, cadmium, and zinc in which crystal twinning is produced by rapid stresses show an abnormally high hardness under impact compared with the Brinell hardness figure. The Brinell hardness figures of 31 elements are recorded, and these when plotted against the corresponding atomic weights give a curve which is very similar to that given by the atomic volumes and melting point respectively. The hardness is a periodic function of the atomic weight.—F. C. Th.

Grain growth in metals. Z. Jeffries. Inst. of Metals, Sep., 1918. [Advance copy.] 32 pages.

In most metals the lowest temperature at which recrystallisation after cold work occurs is 0.35 to 0.45 of the absolute melting point. The recrystallisation temperature is not fixed and for any particular metal will be lowest when a fine-grained sample has been worked as much as possible at a comparatively low temperature. A metal worked at a temperature above that of recrystallisation is composed, after cooling, of equiaxed crystals which will be the larger the higher was the finishing temperature of working. Reheating such a metal above the finishing temperature usually causes grain growth, which may also occur on prolonged heating to a slightly lower temperature. Allotropic changes may also result in grain growth. The velocity of the growth of the crystals is very great during the first stages of recrystallisation, becoming less as the grains grow larger. Abnormal grain growth produced by annealing after cold work at times attains a maximum at a certain temperature. Higher temperatures result in less growth ensuing. The general laws of grain growth are discussed and typical examples are given, including several in metallic tungsten.—F. C. Th.

Ilsemanite, a blue water-soluble molybdenum compound occurring in Utah. H. F. Yancey. Chem. and Met. Eng., 1918, 19, 186—190.

A CONSIDERABLE deposit of molybdenum ore has been found near Ouray, Utah. It is a sandstone containing ilsemanite, a blue compound, soluble in water, to which the formula $\text{MoO}_3 \cdot 4\text{MoO}_3 \cdot 6\text{H}_2\text{O}$ is given. Lead and vanadium are absent. Analysis of an air-dried sample gave: 65.92% SiO_2 , 4.35% Fe_2O_3 , 12.27% Al_2O_3 , 0.35% TiO_2 , 1.36% CaO , 0.50% MgO , 1.22% MoO_3 , 11.09% of sulphur as SO_3 , 1.01% moisture, loss on ignition 4.89%. The dark blue solid obtained from the water-soluble portion contained 23.85% of molybdenum as MoO_3 and 38.5% SO_3 . The blue compound was extracted with ether in a hydrochloric acid solution and the molybdenum occurring as MoO_3 determined by titration with N/100 permanganate. The total molybdenum was obtained by fuming with sulphuric acid and passing the solution through a Jones "reductor" (see Mellor's "Quantitative Inorganic Analysis," 1913, p. 190). The molybdenum may be extracted from the ore with water, dilute acids, dilute alkali carbonates and alkalis, and by roasting with a small amount of the reagents followed by a water leach. The best results, corresponding to an extraction of about 80% of the molybdenum, were obtained with a cold water leach followed by hot treatment with 15% sulphuric acid or by treatment of the ore with caustic soda. (See also J. Chem. Soc., Oct., 1918.)

Bismuth tellurides. Amadori. See VII.

PATENTS.

Hardening, tempering, and case-hardening metal articles; Processes for —. J. J. W. York, Bensham-on-Tyne, and S. W. H. Taylor, Newcastle-on-Tyne. Eng. Pat. 117,761, Nov. 20, 1917. (Appl. No. 17,078 of 1917.)

α -NAPHTHOL, β -naphthol, α -anthranol, β -anthranol, phthalic acid, naphthalene mono- or di-sulphonic acids or salts, anthracene mono- or di-sulphonic acids or salts, and borneol are used in conjunction with water, oils, or other fatty substances for the purposes mentioned.—C. A. K.

Annealing metal wire by electricity; Process of —. H. Alexander and W. T. Vint, Leeds, and A. Imbery, Halifax. Eng. Pat. 117,822, July 30, 1917. (Appl. No. 2878 of 1917.)

PORTIONS of a continuously travelling wire are heated by causing them to form parts of a regulated electric circuit and are cooled by passing through a bath, the operations being repeated in sequence with any variation of heating required, as many times as desired. The wire travels between guide rolls which form the contacts of the electric circuit.

—C. A. K.

Heat treatment of metals; Furnaces for —. H. Rogers and C. M. Walter, Birmingham. Eng. Pat. 117,903, Aug. 9, 1916. (Appl. No. 11,225 of 1916.)

FOR the heat treatment of metals in a neutral or other atmosphere with after-quenching of the metal without exposure to air, a vertical retort is provided, with a removable lid at the upper end, the lower end dipping into a quenching bath. A portion of the retort is heated externally and the desired atmosphere is obtained by passing a suitable gas through an inlet above the bath. The metal article to be treated is suspended from the lid and is heated by radiation from the heated portion of the retort.—C. A. K.

Heat treatment furnaces for metals; Annealing, tempering, or —. J. R. Hoyle and H. S. Burn, Sheffield. Eng. Pat. 118,040, Dec. 4, 1917. (Appl. No. 17,931 of 1917.)

FOR the treatment of metals which require a rapid or special rate of cooling, a fan is provided to supply the air necessary, and may be fixed to draw the hot air from the chamber or to force cold air into the furnace.—C. A. K.

Metals; Deposition of — by electrolysis. M. A. Bolton, Oakamoor, and A. Walker, Stoke-on-Trent. Eng. Pat. 117,872, Nov. 8, 1917. (Appl. No. 16,339 of 1917.)

THE cathode is treated with a solution of wax or the like in petrol or similar solvent containing dissolved hydrogen sulphide, whereby a waxy sub-sulphide film is produced sufficient to produce a coloration. This film prevents adhesion between the deposited metal and the cathode, without unduly increasing the electrical resistance.—C. A. K.

Metals; Electrochemical precipitation of —. E. R. Holden, Los Angeles, Cal. U.S. Pat. 1,269,565, June 11, 1918. Date of appl., Oct. 10, 1916. Renewed Nov. 5, 1917.

THE electrolyte is agitated, and the electric current introduced at a number of points at different distances from the cathode, the voltage at each point being regulated, in accordance with its distance from the cathode, to maintain any desired density of current throughout the solution.—E. N.

Crucible furnaces for melting brass and the like. C. F. Price, Birmingham. Eng. Pat. 118,000, Sep. 19, 1917. (Appl. No. 13,450 of 1917.)

A PORTABLE coke-fired crucible furnace is built so that the outer casing is supported by the grate-bar frame, the outer casing having projecting feet for the support of the internal firebrick lining. The shape of the feet is such as to allow of a circulation of air for the protection of the metal parts.

—C. A. K.

Crucible melting-furnaces heated by gas or oil. L. C. Harvey, and The Morgan Crucible Co., Ltd., Battersea. Eng. Pat. 118,037, Nov. 23, 1917. (Appl. No. 17,302 of 1917.)

To facilitate the removal of spilt slag and metal which has solidified in the base of a furnace, a false cover is suspended over the solidified bed, after the removal of the crucible, thus enabling a high temperature to be generated locally sufficient to melt the spilt material. Drain holes are provided in the bottom of the furnace for the escape of the melted mass.—C. A. K.

Aluminium; Production of —. R. Welford, London. Eng. Pat. 118,312, Aug. 18, 1917. (Appl. No. 11,865 of 1917.)

ALUMINA-BEARING clay or other aluminous material is dried and mixed with hot hydrochloric acid, filtered, and the filtrate evaporated in a still, the acid being recovered. The separated salts are removed from the still to a crucible or heating chamber, and heated to obtain oxides or hydroxides for subsequent reduction to metal in an electric furnace.—T. H. B.

Oxides [e.g., alumina]; Reduction of metallic —. P. R. Hershman, Chicago, Ill., Assignor to The Mineral Products Co., New York. U.S. Pat. 1,273,220, July 23, 1918. Date of appl., Dec. 21, 1914.

ALUMINA is reduced to metal by mixing it with silicon carbide and heating to 2200° C., the gaseous reaction products being quickly and positively removed.—T. H. B.

Aluminium; Process of annealing —. L. H. Whitney, Pittsfield, Mass., Assignor to General Electric Co. U.S. Pat. 1,273,706, July 23, 1918. Date of appl., May 7, 1917.

ALUMINIUM containing dissolved silicon is annealed by heating it rapidly to about 370° C. to 450° C., maintaining the temperature until the aluminium is softened, then quickly chilling so as to prevent the formation of appreciable quantities of graphitoid silicon.—T. H. B.

Aluminum-solder. D. M. Campbell, Brooklyn, N.Y. U.S. Pat. 1,273,146, July 23, 1918. Date of appl., Aug. 22, 1917.

ALUMINIUM solder having a melting point substantially that of ordinary solder consists of copper, 6 to 8%; aluminium, 7 to 11%; lead, 12 to 15%; tin, 20 to 30%; and zinc, 40 to 50%.—C. A. M.

Zinc-distilling furnace and condenser; Electric —. J. Thomson, New York, Assignor to J. Thomson Press Co., Jersey City, N.J. U.S. Pat. 1,265,973, May 14, 1918. Date of appl., Jan. 19, 1916.

THE condenser is provided with a number of transverse plates, and the fume from the furnace passes between the plates and around their ends. Near the outer end of the condenser the plates extend the full width of the condenser except where the upper parts of the ends are cut away to allow the passage of fume. In each of the sections bounded by these latter plates the condensed metal is kept separate, whereas in the sections formed by the earlier plates the condensed metal collects to form a common bath. By suitable regulation of the temperature in the condenser, practically pure zinc is collected in this common bath, and nearly the whole of the cadmium in the condensed metal in the separate sections at the outer end of the condenser. The metal may be drawn from the different sections of the condenser by means of trapped taps.—C. A. K.

Zinc vapour; Apparatus and method for condensing —. C. H. Fulton, St. Louis, Mo., Assignor to Metallurgical Laboratories, Inc., Chicago, Ill. U.S. Pat. 1,271,560, July 9, 1918. Date of appl., Jan. 8, 1917.

ZINC vapours from the furnace are conducted through an annular passage between concentric tubular chambers, which may be either heated or cooled. Baffle-plates are provided to act as condensing surfaces.—C. A. K.

Phosphorus; Process for making alloys of —. L. A. Jeffs, Salt Lake City, Utah. U.S. Pat. 1,268,849, June 11, 1918. Date of appl., Nov. 13, 1917.

A MIXTURE of a phosphate rock, carbon, a suitable compound of the required metal, e.g., copper, and a flux, is placed in an electric furnace and a sufficiently strong current is passed to maintain a fusion zone in which oxides of phosphorus and the molten metal are liberated. An excess of carbon is used to ensure the reduction of the oxides of phosphorus.—B. V. S.

Metal coating. E. W. McMullen, Assignor to Simmons Co., Kenosha, Wis. U.S. Pat. 1,268,987, June 11, 1918. Date of appl., Feb. 11, 1918.

A COATING of zinc is electrolytically deposited on the surface of steel or other ferrous metal articles, the deposit itself being afterwards coated with a cellulose laquer.—C. A. K.

Galvanised iron. J. H. Gravell, New York. U.S. Pat. 1,273,358, July 23, 1918. Date of appl., Mar. 23, 1918.

GALVANISED iron is provided with a superficial coating of zinc phosphate and over the latter an adherent coating of paint.—B. N.

Alloy; Soft [bearing] metal — and method of making same. W. L. Rice, Assignor to P. S. Braucher, Reading, Pa. U.S. Pat. 1,269,000, June 11, 1918. Date of appl., June 27, 1916.

AN alloy of lead, tin, antimony, and sodium is prepared by adding caustic soda to a molten mixture of tin and antimony, mixing the molten product with lead, then adding a further quantity of caustic soda.—T. H. B.

Waste pickle liquor; Method of treating —. *Process of producing by-products from waste pickle liquor.* (A) A. F. Hoffman and W. M. Parkin, (B) A. F. Hoffman, Pittsburgh, Pa. U.S. Pat. (A) 1,269,441 and (B) 1,269,442, June 11, 1918. Date of appl., Apr. 8, 1916. Renewed Nov. 10, 1917.

(A) SPENT pickle liquor is evaporated and ferrous sulphate crystals are separated and pulverised. The acid mother liquor is used again for pickling. The ferrous sulphate is allowed to oxidise and the product heated in the presence of steam at a temperature between 179° C. and 338° C. to recover ferric oxide and sulphuric acid, the acid vapours evolved being absorbed in waste pickle liquor. (B) Waste pickle liquor is treated with calcium and magnesium compounds to precipitate the soluble iron salts as hydroxides, the sludge being dried and calcined in such a manner as to reduce the calcium sulphate. The alkaline-earth sulphide is removed from the calcined product by leaching with a suitable liquid.—C. A. K.

Pickling process and bath. A. F. Hoffman, Pittsburgh, Pa. U.S. Pat. 1,269,443, June 11, 1918. Date of appl., Jan. 23, 1917. Renewed Nov. 10, 1917.

THE article to be pickled is subjected to the action of a pickling bath which is afterwards restored to

an active condition by treatment with an oxidising agent in presence of an oxygenating catalyst (e.g., a manganese compound) at a boiling temperature. —C. A. K.

Electric welding process. H. A. Newcomb, Wilkesburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,270,860, July 2, 1918. Date of appl., May 11, 1914.

METALS having different melting points are heated unequally by the passage of an electric current. In somewhat relative proportion to their melting points, and are at the same time pressed together until surface fusion is effected. Iron or steel articles may be welded by fitting a refractory metal plug (e.g., of tungsten type) into recesses formed in the ends of the articles and applying heat and pressure to weld the refractory metal in the recesses.—C. A. K.

Furnace [for reduction of tungsten]; Electric —. C. A. Pfanstiehl, Highland Park, Ill., Assignor to Pfanstiehl Co., Inc., North Chicago, Ill. U.S. Pat. 1,271,760, July 9, 1918. Date of appl., Oct. 30, 1916.

A TUBE of refractory material is surrounded by a heating element, and a protecting lining of nickel covering the inner wall of the tube is provided within and insulated from the heating element for protecting the walls of the furnace from the sub-oxides of tungsten. Means are provided for supporting the tungsten trioxide, to be reduced to metallic tungsten, within the metal lining.—B. N.

Converter lining. F. E. Hanners, Milwaukee, Wis. U.S. Pat. 1,272,442, July 16, 1918. Date of appl., Oct. 19, 1917.

A LINING is made, shaped, and burned, and is afterwards inserted in the shell with a wet packing between the lining and the shell.—C. A. K.

Removing enamel from enamelled metal articles. R. D. Cooke, Assignor to Columbian Enamelling and Stamping Co., Terre Haute, Ind. U.S. Pat. 1,272,917, July 16, 1918. Date of appl., Sep. 5, 1917.

THE enamel is rendered porous by an acid solution and then loosened by an alkali; for example the articles are treated with 10% hydrochloric acid heated to 160° and then with 25% sodium hydroxide at 160°.—J. H. P.

Platinum and similar metals; Extraction of — from their sands and ores. R. Thayer, Philadelphia, Pa. U.S. Pat. 1,273,202, July 23, 1918. Date of appl., Aug. 15, 1917.

THE sand or ore is mixed with metallic mercury, with or without an alkali metal, and the mercury distilled off at a temperature below the melting point of platinum or similar metals, the distilled mercury and "volatilised platinum" being collected in water and suitably separated.—T. H. B.

Cerium and the like; Process of making —. A. and M. Hirsch, New York, Assignors to Alpha Manufacturing Co. U.S. Pat. 1,273,223, July 23, 1918. Date of appl., Sep. 1, 1917.

FUSED chloride of cerium and similar rare earth metals is electrolysed, and during the electrolysis hot, dried solid portions of the chloride are added to the bath to maintain the temperature at about 850° C. The cathode current density used is sufficient to cause lanthanum and didymium to separate with cerium, and the portion of the anode

above the electrolytic bath is protected by a coating of the electrolyte. A terminal voltage of less than 12 volts is used and an anodic current density of less than 8 amp. per sq. in.—T. H. B.

Nickel; Method of separating — from nickel-copper alloys. J. Dlavernas, Assignor to United States Nickel Co., New Brunswick, N.J. U.S. Pat. 1,273,465, July 23, 1918. Date of appl., Sep. 8, 1917.

COPPER-NICKEL matte is roasted, then reduced to metal, and treated with neutral or slightly acid copper solution to dissolve the nickel. The solution is treated with metallic nickel to precipitate traces of copper, and the solution of nickel salts drawn off.—T. H. B.

[Aluminium] alloy. T. S. Fuller, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,273,762, July 23, 1918. Date of appl., May 24, 1917.

AN aluminium alloy containing about 6–12% Zn, 0.5–2.5% Mg, and 1–3% Fe.

Electric welding. S. C. Cary, Brooklyn, N.Y., U.S.A. Eng. Pat. 118,138, Aug. 10, 1917. (Appl. No. 11,511 of 1917.)

Tin-plates; Manufacture of —. C. D. Godfrey and A. J. Way, Briton Ferry, Glam. Eng. Pat. 118,377, Dec. 5, 1917. (Appl. No. 18,053 of 1917.)

Alloys. The Cooper Co., Assignees of H. S. Cooper, Cleveland, Ohio, U.S.A. Eng. Pat. 113,259, May 14, 1917. (Appl. No. 6846 of 1917.) Under Int. Conv., Oct. 30, 1916.

SEE U.S. Pat. 1,221,769 of 1917; this J., 1917, 556.

Wires; Process for the manufacture of — from refractory materials [e.g., tungsten]. A. Lederer, Vienna, Assignor to Westinghouse Lamp Co. U.S. Pat. 1,273,506, July 23, 1918. Date of appl., May 16, 1914.

SEE Eng. Pat. 12,358 of 1914; this J., 1915, 967.

Process for the recovery of potassium salts from blast-furnace flue dust or the like. Eng. Pat. 117,991. See VII.

Method of recovering sulphur dioxide from furnace gases. U.S. Pat. 1,271,899. See VII.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Furnaces or other appliances; Supply of electrical energy to —. W. Travis, and T. H. Watson and Co. (of Sheffield), Ltd., Sheffield. Eng. Pat. 118,233, Feb. 27, 1918. (Appl. No. 3460 of 1918.)

THREE-PHASE current is distributed to electric arc or resistance furnaces, or other similar appliances consuming electrical energy and having unequal resistances, by an improved method so that the loads on the several phases are balanced one with another in the power and power factor. The three transformer secondary windings, grouped in open delta fashion, are arranged so that the two windings, connected to the two top electrodes, are connected to the ends of the transformer winding connected to the furnace hearth or bottom electrode, and each makes a vector angle of 120° therewith. The two first-named transformer windings are identical in voltage and capacity, and the last-named

transformer winding is less than either of the other two, and varies in its relation thereto according to the relative resistance of the furnace hearth to the normal resistance of the electric arc of the furnace between the two upper electrodes and the charge in the furnace. In an alternative method two of the transformer secondary windings are connected in mesh or delta fashion, and are connected at their meeting ends to the hearth or bottom electrode of the furnace. The other secondary winding is split, each portion being connected to the open ends of one of the last-named windings and making a vector angle of 120° therewith, and also connected to one of the two upper electrodes. From the above arrangements, when the hearth is non-conductive, the current passing from one top electrode to the second top electrode must traverse all three transformer secondary windings in series. In a further arrangement, the secondary windings are connected by the "Scott" method, the two ends of one transformer winding being connected to the upper electrodes, whilst the ends of the other transformer winding are connected respectively to the middle point of the first-named winding and to the hearth or lower electrode.—B. N.

Furnaces; Electric —. H. Wade, London. From Booth-Hall Co., Chicago, Ill., U.S.A. Eng. Pat. 118,357, Sep. 27, 1917. (Appl. No. 13,956 of 1917.)

THE furnace is formed of a heating chamber, the hearth of which is conductive when hot, and is provided with a wall terminal embedded in the hearth underneath a co-acting main electrode of opposite polarity, automatically adjustable. An auxiliary electrode, adjustable by hand, of the same polarity as the wall terminal, is adapted to give the furnace a preliminary heating. One terminal of the secondary circuit of a transformer is connected to the main electrode, and the second terminal with both the wall terminal and the adjustable auxiliary electrode. Several wall terminals, with refractory facings which are conductive when hot, may be arranged in the hearth with main electrodes directly above them, and the furnace is supplied with two-phase or three-phase current, the secondary circuits on one side being connected with the main electrodes, and on the other side with the wall terminals and the auxiliary electrode. The secondary circuits are provided with connections whereby one conductor from the auxiliary electrode is used in common on one side of the circuits, and a conductor is also included in the circuit between the wall terminals, the conductor having a switch which is opened when the auxiliary electrode is withdrawn.—B. N.

Furnace; Electric —. W. E. Moore, Pittsburgh, Pa. U.S. Pat. 1,272,077, July 9, 1918. Date of appl., Sep. 11, 1917.

THE furnace is provided with three arcing electrodes, an electrically-conducting shell, and a bottom composed of a mixture of refractory material increasing in electrical conductivity towards the lower face. Transformer secondaries are connected to the electrodes in Y formation, the neutral point being connected to the conducting shell. Switches are provided for connecting the transformer primaries either in delta or Y formation, and thus varying the voltage of the electrode arcs at will. A circulation of the molten bath is produced.—B. N.

Electric furnace contact. F. T. Snyder, Oak Park, Ill. U.S. Pat. 1,271,093, July 2, 1918. Date of appl., Mar. 1, 1917.

A hollow contact extending through the bottom of the furnace contains a cooling medium, and is provided with ribs projecting from the inside and

outside so as to increase the surface, whereby the contact has a relatively high conductivity for alternating current and a low conductivity for heat. The end of the contact projecting below the bottom of the furnace is encircled by a strap, and means are provided for clamping conductor ends between the ends of the strap, for conducting current to the contact, and for protecting the strap and conductors against injury.—B. N.

Furnace; Electric —. E. F. Collins, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,271,280, July 2, 1918. Date of appl., May 12, 1917.

PRISMATIC electrical conductors are arranged in pairs on the base of the furnace, so as to form recesses with upwardly diverging sides. Replaceable conductive blocks are fitted in the recesses in electrical contact with the conductors, and an adjustable electrode co-operates with each block to support an electric arc.—B. N.

Furnace; [Electric] melting —. T. F. Bally and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,272,186, July 9, 1918. Date of appl., Sep. 4, 1917.

THE heating chamber is provided with a hearth located at the bottom of the chamber, and with spaced walls within the chamber, above the hearth. A circular resistance element in the form of a trough is supported on the spaced walls, and heat rays radiating upwards from it are reflected by the roof down on to the hearth, whilst heat rays radiating downwards strike directly on the hearth.—B. N.

Electrolytic tank for electro-chemical reactions. E. H. Hamilton, Trail, British Columbia, Assignor to The Consolidated Mining and Smelting Co. of Canada, Ltd., Toronto, Canada. U.S. Pat. 1,269,078, June 11, 1918. Date of appl., Oct. 4, 1917.

AN electrolytic tank is provided with electrodes, and with a hollow baffle, which is interposed between the tank inlet and the adjacent electrode, the inflowing electrolyte being thus directed below the electrodes. The baffle is provided with an inlet and outlet to allow of the circulation of an agent for regulating the temperature, and also with interior strengthening pieces, which resist distortion of the baffle whilst permitting circulation of the fluid.—B. N.

Electrode. A. T. Stuart, Assignor to The Toronto Power Co., Ltd., Toronto, Canada. U.S. Pat. 1,269,128, June 11, 1918. Date of appl., July 5, 1917.

THE electrode is composed of current distributors, and a number of metallic strips arranged parallel to each other and with the rear edge of each strip in contact with the distributors, the width of the strip being at an appropriate angle to the surface formed by the front free edges of the strips. The strips form current-conducting paths, and the unobstructed spaces between them permit freedom of movement of the electrolyte and the electrolytic products of the reaction. The lengths of the strips are many times their width or diameter or thickness.—B. N.

Depolarisers; Process of making battery —. H. F. French and R. C. Benner, Fremont, Ohio, Assignors to National Carbon Co., Inc. U.S. Pat. 1,269,173, June 11, 1918. Date of appl., Nov. 21, 1916.

COPPER oxide is reduced by an excess of sulphur, and the mass re-oxidised in the presence of the excess of sulphur.—B. N.

(A) Depolariser; Organic manganese-compound —.

(b) *Process of making conducting hydrated black manganese dioxide.* (c) *Process of making manganese dioxide [depolariser].* (d) *Poly-acid of manganese depolariser.* (A and B) C. Ellis, (B and C) C. Ellis and A. A. Wells, Montclair, N.J., Assignors to National Carbon Co., Long Island City, N.Y. U.S. Pats. (A) 1,269,913, (B) 1,269,914, (C) 1,269,915, (D) 1,269,916, June 18, 1918. Dates of appl., (A) Oct. 18, 1915, (B) Dec. 2, 1915, Renewed Feb. 8, 1918, (C) Dec. 6, 1916, (D) Jan. 17, 1917.

(A) MANGANESE dioxide is treated with glycerol in the presence of an alkali, and the product of the reaction decomposed, whereby hydrated manganese dioxide is obtained. (b) Manganese sulphate, in a solution containing not more than 0.5 to 1% of free acid, is oxidised by sodium hypochlorite, and the sulphuric acid liberated is progressively neutralised so as to maintain the acidity at the above value. (c) A grey or ash-coloured manganese dioxide depolariser is produced by oxidising a slightly acid boiling solution of manganese chloride containing hydrochloric acid by means of a hypochlorite, and progressively neutralising the acid formed. (d) A depolariser for a Leclanché cell consists of a poly-acid of manganese dioxide substantially free from salts of poly-manganous acid.—B. N.

Depolariser; Electric battery —. M. E. Holmes, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,272,952, July 16, 1918. Date of appl., Jan. 7, 1916.

A DEPOLARISER for primary batteries contains molybdenum trioxide.—B. N.

Electrolytic apparatus. A. J. MacDougall and G. N. Middleton, Assignors to The Toronto Power Co., Ltd., Toronto, Canada. U.S. Pat. 1,269,566, June 11, 1918. Date of appl., July 5, 1917.

AN electrolytic cell is provided with electrodes and with an insulated "off-take," the diameter of which bears such proportion to its length that the electrolyte may circulate with negligible shunt-current losses, and so that the evolved gases during their ascent through the "off-take" convey with them portions of the electrolyte. Gas-separating means are provided, through which the evolved gases and portions of the electrolyte are caused to circulate for their separation, and the separated electrolyte, the temperature of which is regulated by suitable means, is returned through an insulated arrangement to the cell.—B. N.

Electrolyte-feeding device. F. G. Wheeler, Assignor to Bleach Process Co., Appleton, Wis. U.S. Pat. 1,269,666, June 18, 1918. Date of appl., June 18, 1917.

THE tank in which the level of liquid is to be maintained is connected with an upper supply tank by a sealed conduit provided with an air-trap portion at an intermediate point in its length, the air-trap consisting of a pressure chamber having an overflow port communicating with the conduit, and a lower feed-port communicating with the liquid of the supply tank. The lower end of the conduit is immersed in the liquid in the lower tank, so as to include a body of gas extending from the top of the trap to the bottom of the immersed open end of the conduit, the gas being under a pressure substantially equal to the depth of immersion of the open end in the electrolyte. The pressure of liquid in the supply tank is maintained constant at the outlet, and in amount sufficient to force liquid therefrom up to the overflow level of the trap.

—B. N.

Electrolysis; Apparatus for effecting —. A. Dohmen, Cologne, Germany, Assignor to A. F. Krause, Buffalo, N.Y. U.S. Pat. 1,272,397, July 16, 1918. Date of appl., Dec. 1, 1914.

AN electrolytic cell of the filter-press type comprises frameless, sheet nickel bi-polar electrodes, less than 1 mm. in thickness, alternating with diaphragm-supporting members in the form of frames. Rigid parallel flanges are provided within the frame opening, and a diaphragm is held within the opening between the parallel flanges in crimped connection, thus dividing the interior of the frame into two compartments. Two transverse gas passages are arranged through the top of the frame, and these passages are respectively connected with the compartments on each side of the diaphragm by enlarged chambers extending laterally; the electrodes are similarly provided with holes registering with these passages.—B. N.

Electrolysing apparatus. H. C. L. Gougnard, Paris, Assignor to The Linde Air Products Co., Cleveland, Ohio. U.S. Pat. 1,273,357, July 23, 1918. Date of appl., Sep. 4, 1915.

AN apparatus of the filter-press type comprises a series of electrolysing elements clamped together, and supported by lugs on parallel insulated rods on which the elements may be shifted lengthwise. Each element is composed of a diaphragm held between two insulating frames forming cells on opposite sides of the diaphragm, and a metal plate electrode applied to one of the frames, over the cell parallel with the diaphragm. The several elements are provided with registering openings forming an electrolyte conduit communicating with all the cells, and gas conduits each of which communicates with alternate cells through passages in the frames.—B. N.

Electrolyte for electrolytic cells, such as lightning-arresters, condensers, and the like. L. W. Chubb, Edgewood Park, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,270,784, July 2, 1918. Date of appl., Oct. 2, 1914.

A FILM-FORMING electrolyte is composed of a solution of boric acid and ammonium borate, the number of gram-molecules of boric acid present being 45—98%, preferably substantially 97%, of the total gram-molecules of soluble material.—B. N.

Electrolytes for electrical etching; Composition for —. J. H. Weeks, Rutledge, Pa., Assignor to J. S. Weeks, Delaware Co., Pa., and R. M. Weeks, Philadelphia. U.S. Pat. 1,273,432, July 23, 1918. Date of appl., Apr. 4, 1917.

THE electrolyte is composed of one or more of the oxalates of ammonium, barium, calcium, cadmium, magnesium, iron, potassium, sodium, or strontium, dissolved in water, together with a sulphate, a chloride, and an acid.—B. N.

Electrical furnace. H. Nathusius, Friedenshütte, Germany. U.S. Pat. 1,265,485, May 7, 1918. Date of appl., Oct. 5, 1914. Renewed Mar. 30, 1918. See Eng. Pat. 13,951 of 1914; this J., 1916, 547.

[*Electrolytic*] **process of making combustible gas.** U.S. Pat. 1,273,050. See IIa.

Method of electrolytic production of perchloric acid. U.S. Pat. 1,271,633. See VII.

Preparation of potassium persulphate by electrolysis. Ger. Pat. 306,194. See VII.

XII.—FATS; OILS; WAXES.

Oil seeds from Sierra Leone; New —. Bull. Imp. Inst., 1918, 16, 35–40.

Pentadesma butyracea, "butter or tallow tree," is a large tree, which occurs sparsely in West Africa, but which could be planted if a demand for the seeds arose. The kernels are large, reddish-brown, and irregular in shape; the samples arrived with 29% of moisture but the kernels could be dried before shipment so as to yield about 40% of fat. The fat is equivalent to 41.8% on the dry substance, pale yellow in colour and rather soft. The following data were obtained:—Sp. gr. at 100°/15° C., 0.8565; m.pt., 33° C.; acid value, 17.4; saponification value, 191.7; iodine value, 42.8%. The residual meal cannot be used for feeding purposes and contains only a small proportion of nitrogen. *Piassava oil*. A sample, presumably obtained from the fruit of a species of *Raphia*, had a dark orange-red colour and contained a fair proportion of separated stearine; it was darker and more liquid than palm oil. The sample showed:—Sp. gr. at 15°/15° C., 0.919; solidifying point of fatty acids, 41.1° C.; acid value, 6.2; saponification value, 192.7; iodine value, 79.5%; Hehner value, 94.7; insoluble fatty acids, 92.6%; unsaponifiable matter, 2.1%; volatile acids, soluble, 0.3; ditto, insoluble, 0.2. This oil is similar in character to ordinary palm oil and would have the same commercial value. "*Po-Yoak*" nuts and oil. These nuts are almost spherical, 1.3 in. diam., with rough dark brown shell. The kernel has a slightly wrinkled, light brown surface and the flesh is fairly soft, dark reddish-brown, and very oily; it has a peculiar odour resembling that of tung oil. The nuts are probably derived from a species of *Parinarium*. The sample of oil received possessed the same odour; it was pale yellow with a considerable deposit of "stearine." Analysis showed:—Sp. gr. at 15°/15° C., 0.963; solidifying point of fatty acids, 30.6° C.; acid value, 2.6; saponification value, 189.1; iodine value, 156.9%; unsaponifiable matter, 0.84%. The high iodine value of the oil indicates that it belongs to the class of "drying" oils; the skin formed on drying is rather rough and not transparent. The oil could be used for the manufacture of paints and varnishes; it becomes thick like linseed oil on heating at 280° C.

Determination of chlorine in mixtures containing silicates. Bruhns. See VII.

PATENTS.

Oils; Preparing catalytic agents for hydrogenating —. K. Kimura, Kobe, Japan. Eng. Pat. 118,323, Aug. 22, 1917. (Appl. No. 12,032 of 1917.)

A powdered nickel salt is mixed with a non-combustible non-catalytic substance such as powdered asbestos or pumice, and the mixture dried and heated in a vessel made of non-catalytic material, while ammonia gas or a vaporised ammonium compound, such as ammonium chloride, is passed through it. Catalytic material thus prepared acts at a relatively low temperature.—C. A. M.

Oily material containing unsaturated bodies; Hydrogenating —. *Hydrogenation of unsaturated bodies*. M. H. Ittner, Jersey City, N.J. U.S. Pats. (a) 1,271,575 and (b) 1,271,576, July 9, 1918. Dates of appl., May 6, 1914, and Sep. 27, 1915.

(a) MATERIAL containing unsaturated compounds is mixed with a catalyst and forced through an orifice

communicating with a supply of hydrogen or gas containing hydrogen, so as to cause the gas to be drawn into the mixture and intimately mixed therewith. The mixture is then discharged into an enclosed space containing an atmosphere of hydrogen and also more of the mixture of unsaturated substance and catalyst, and may be made to pass well beneath the surface of the mixture in the container. (b) Oily material is mixed with a catalyst and forced, e.g., centrifugally outwards, through an orifice below the surface of the material. This orifice communicates with a supply of hydrogen which thus becomes entrained by the oil and catalyst and intimate admixture effected. On continuing the circulation of the mixture through the apparatus further amounts of hydrogen are entrained until the desired degree of hydrogenation is obtained, whilst the resulting currents are arrested by means of barriers such as wire screens or baffles to prevent the formation of a vortex.

—C. A. M.

Oils and the like; Apparatus for extracting —.

R. Wells, Homer, N.Y., Assignor to Cobwell Corporation, Cleveland, Ohio. U.S. Pat. 1,272,744, July 16, 1918. Date of appl., Apr. 23, 1915.

THE apparatus comprises a cylindrical chamber for the material to be treated, provided with a central vertical shaft, driven from outside, and carrying radial arms close to the bottom of the chamber, whilst arms freely suspended independently on pivots at intervals along a radius of the chamber engage the upper portion of the mass as it is agitated by the radial arms.—C. A. M.

Process for the separation of grease from wool scouring or like effluents. Eng. Pat. 118,332. See V.

Treatment of linseed oil fatty acids. Eng. Pat. 118,228. See XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Varnishes; Hardness and viscosity of —. R. P. L. Britten. Oil and Colour Chem. Assoc., Sep. 17, 1918.

THE varnish maker's practical "thumb-nail test" is inadequate, as it fails to give quantitative expression to the results obtained. The mechanical hardness testers of Laurie and Baly, Jahns, and Clemens measure toughness rather than hardness. The author described a method which would determine true hardness, and which was based on the principle of the hardness of minerals scale, scratching points of various crystals of known relative hardness being used. A method embodying the use of gelatin points of differing water content and registering results obtained in degrees of water was also suggested. Of the various types of instruments for determining viscosities of the widely differing types of varnishes, those in which force as against time, was the factor determined, are recommended. The author has elaborated a type of viscometer having for its principle the determination of the time taken for a glass or metal ball suspended on one arm of a balance of high moment of inertia to fall a definite distance through the liquid the viscosity of which has to be determined. The times taken under similar conditions in air and in water serve for the standardisation of the instrument ("retardation for water"). Viscosity is calculated as time taken in the liquid

less time taken in air, divided by the retardation for water. As equilibrium is readjusted after immersion of the ball, a correction is made for specific gravity. In this way values were obtained for four characteristic oils as follows:—linseed oil, 7.7; olive oil, 10.5; rape oil, 12.1; castor oil, 200.

New oil seeds from Sierra Leone. See XII.

PATENTS.

Linseed oil fatty acids: Treatment of —. Barry, Ostlere and Shepherd, Ltd., and J. Barry, Kirkcaldy. Eng. Pat. 118,228, Feb. 5, 1918. (Appl. No. 2037 of 1918.)

LINSEED oil fatty acids are rendered readily oxidisable, and thus suitable for the manufacture of linoleum and paints, by subjecting them to the action of superheated steam, preferably after heating in a steam-jacketed pan. The superheated steam decomposes any metallic compounds present, expels volatile deleterious substances, and acts as an oxidation catalyst.—C. A. M.

Impregnated material: Manufacture of —. J. Rosen, Assignor to Soc. Anon. des Combustibles Industriels, Paris. U.S. Pat. 1,273,673, July 23, 1918. Date of appl., Jan. 11, 1915. Renewed May 29, 1918.

THE basic material is dehydrated, and coated first with a layer of tar oils, then with tale, and then with successive layers of tar oils having different degrees of oxidation from that of the first coating.—C. A. M.

Treatment of textile fabrics, wood, leather, and other materials. Eng. Pat. 117,640. See V.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanised rubber; Porosity of —. Remarks on the nature of the vulcanisation process. G. van Iterson. Communications of the Netherlands Govt. Inst. for Advising the Rubber Trade and the Rubber Industry. Int. Assoc. for Rubber Cultivation in the Netherland Indies, 1916 (in Dutch; 1918 in English), Part VII., 224–261.

RUBBER articles vulcanised in direct steam without precautions being taken to prevent condensation on their surface become superficially porous. Every rubber mixing, however, may be made to yield an internally porous product by under-vulcanising in direct steam and then releasing the steam pressure suddenly. Internal porosity is also frequently observed in vulcanite, but can be prevented by raising the temperature very slowly at the commencement and releasing the steam pressure very gradually at the end, a period of 1½ hours being none too long for each of these operations. The internal porosity is due to the presence of moisture in the rubber-sulphur mixture, even normally masticated rubber sometimes retaining 0.2 to 0.3% of moisture; this explanation of the origin of the porosity is confirmed by experience with oil bath vulcanisation (this J., 1918, 215 A), and by experiments in which the development of water vapour bubbles was prevented by an external pressure of steam or even of air. Under-vulcanised rubber is much more liable than well-vulcanised rubber to the development of porosity, because when the external pressure of the rubber is suddenly released, the temperature being still above 100° C., the under-vulcanised rubber is in a very soft, plastic condition, with low tensile strength, and the vapour pressure of the included

water causes the formation of cavities which still persist when, on cooling, the plasticity gradually becomes replaced by elasticity. In vulcanising bulky articles porosity is likely to occur because there may be a lag in the vulcanisation of the interior, which will also remain warm and plastic longer than the exterior after the release of the steam pressure. It is also possible that during the earlier stages of vulcanisation the vapour pressure may, for various reasons, locally exceed the pressure predominant in the vulcanisation apparatus, with the result that porosity may be developed which may then be rendered permanent by the further progress of the vulcanisation process. In a review of the work of the Institute and of other investigators on the nature of the vulcanisation process the following views are expressed. The sulphur becomes definitely "bound" by the rubber during vulcanisation, but the limit of combination probably is not reached at the proportions 32:68, corresponding with the composition $C_{10}H_{16}S_8$; no final evidence as to the reversibility of vulcanisation is yet forthcoming. The nature of the curve representing the variation in the rate of vulcanisation with alteration in the amount of sulphur in the mixing is largely dependent on the latter; with less than 10% of sulphur the curve is almost rectilinear, whereas above this percentage the curve takes the S shape characteristic of an autocatalytic process. In the initial stages of vulcanisation of mixtures containing a high percentage of sulphur the rate of fixation of the sulphur is dependent on the limited solubility of the latter in rubber; as the rubber becomes vulcanised its solvent power gradually increases, and therefore assists the autocatalytic effect in causing the gradual steepening of the vulcanisation coefficient—time curve (see also Skellon, this J., 1915, 671); the initial rate of combination is therefore not proportional to the concentration of sulphur when the latter is high, viz. above 10%. The continuity of the changes induced by vulcanisation, whether by sulphur or by sulphur chloride, together with the considerable effect produced by quite small percentages of "combined" sulphur or sulphur chloride, leads the author to favour the view that a colloidal process plays an important part, and that either the vulcanising agent or a chemical compound of this with part of the rubber becomes colloidal bound with the remaining rubber, forming a complex which is insoluble in the ordinary rubber solvents. Consideration is given to the possibility that the various allotropic modifications of sulphur may be involved in the vulcanisation process, and attention is again drawn to the fact that the common organic accelerators of vulcanisation are also effective catalysts in the inter-transformation of S_8 and S_2 (compare this J., 1917, 787), but no definite conclusion is attained.—D. F. T.

Mottling of [vulcanised] Para rubber; Nature of —. H. Rimpel. Gummi-Zeit., 1916, 31, 144. Chem.-Zeit., 1918, 42, Rep., 119.

THE sample examined was free from substitute, and yielded only about 3% of ash. The lightest patches contained twice as much free sulphur as the darkest. The formation of the patches is explained as follows:—After vulcanisation the sulphur which has not combined chemically with the rubber passes on cooling into the amorphous or the rhombohedral form, except at the surface, where octahedral crystals quickly separate. Sulphur wanders from the interior of the sample to the surface, and the sample "sulphurs up." At the same time, however, there occurs conversion of the less stable into the more stable form within the sample, the rubber acting as a solvent, and sulphur wanders from certain parts of the solution and accumulates round other centres.—E. W. L.

XVI.—SOILS; FERTILISERS.

Nitrification in natural soils and its importance from an ecological point of view. H. Hesselmann. Skogsvårdsföreningens Tidskrift, 1917, 15, 312—446. Bull. Agric. Intell., 1918, 9, 662—665.

A STUDY of the nitrogen cycle in forest-soils. The author distinguishes between “sweet” humiferous soils, well aerated by the action of worms and insects, and “strong” humiferous soils, formed of dead decomposed or decomposing vegetation, the former being characteristic of deciduous forests and, to a lesser degree, of pine forests on soils rich in inorganic salts, the latter, on the contrary, being found in pine forests of the ordinary type, and often forming a series of layers, with varying stages of decomposition, which can be clearly separated from the mineral subsoil. The sources of nitrogen in forest soils are the dead, decomposed covering, to the nitrogen of which is added the atmospheric nitrogen fixed by leguminosae, alders, and other plants; the soil fungi and bacteria which can fix nitrogen, and which obtain their energy for this fixation by decomposing the organic matter in the soil; the ammonia and nitric acid in rain. In naturally wooded land the second factor is the most important one. The processes of nitrate formation in forest soils were investigated by the examination of the soil for nitrifying bacteria, the determination of the nitrifying capacity of the soil, and determination of the nitrogen content of the trees and plants at different seasons, the following conclusions being drawn. The “sweet” humus of beech woods contains as many nitrifying as denitrifying bacteria and has considerable nitrifying power, and the herbs and grasses also help considerably to increase the stock of nitrogen in

such a type of soil. The humus of pine forests with a mossy covering is characterised on the other hand by the absence of nitrifying and denitrifying bacteria, and no potassium nitrate can be found in the tissues of the plants covering the soil. With regard to the acidity of the dark humic soils of pine woods, the author observes that, as colloids are coagulated by the addition of inorganic salts, the humus lying on a subsoil very rich in soluble inorganic salts is less likely to give an acid reaction, because the humus particles are flocculated, thus allowing the penetration of roots, worms, and insects, all of which favour the aeration of the soil. Many natural soils have the power of nitrification, and it is characteristic that humus formation in such soils takes place under the influence of electrolytes, the formation of “sweet” humus being facilitated by the action of worms and insects. In many places nitrification is so rapid that there is a considerable accumulation of nitrogen in the covering vegetation, as in dense beech, elm, oak, ash, and alder forests. Nitrification is not only largely influenced by the origin of the soil, but also by the climate, and as the degree of nitrification constitutes a powerful factor determining the composition of the plant associations of a given soil, the factors of the soil formation may have a decisive influence, in certain cases, on that composition. Thus the same forest trees grow more rapidly on soils where nitrification takes place than where there is no nitrification, and a suitable forest system should make it possible to thin numerous forests so as to favour soil nitrification, thus assuring a higher yield of wood, although a good yield of pine and spruce wood can be obtained on soils where there is no nitrate formation. In the latter case rate of growth is governed by the rate of ammonification, and the formation of the soil might well be influenced by a suitable system of forest management.—W. G.

Phosphates; Influence of nitrifying bacteria on — C. G. Hopkins and A. L. Whiting. Univ. of Illinois Agric. Exp. Stat., Bull. 190 (June, 1916), 395-406. Bull. Agric. Intell., 1918, 9, 790—791.

EXPERIMENTS showed that during the conversion of ammonia into nitrite by nitrite bacteria, there was also an action on any insoluble phosphate present, a portion being rendered soluble. About 1 lb. of phosphorus and 2 lb. of calcium were dissolved for each pound of nitrogen oxidised. Nitrate bacteria and ammonia-producing bacteria did not convert insoluble phosphate into soluble compounds, but certain acid-producing bacteria did so. The amounts of calcium and phosphorus rendered soluble in this manner by biochemical action exceed the requirements of a crop.—J. H. J.

Nitrogen fixation and losses of nitrate in the soil; Influence of plant residues on — H. B. Hutchinison. J. Agric. Sci., 1918, 9, 92—111.

LABORATORY, pot, and field experiments have been conducted to determine the effect of carbohydrates (sugar and starch) and plant residues, as sources of energy, on nitrogen fixation by *Azotobacter*. In the laboratory experiments, under suitable conditions, an increment of upwards of 6 mgrms. of nitrogen per gm. of plant residues occurred, and in pot experiments gains of 9 mgrms. per gm. of substance were obtained. In the field experiments definite increases of crops, equal to 20—54%, were obtained by the application of sugar (at the rate of 1 ton per acre per annum) when the soil conditions were favourable. The difference between the action of plant residues and sugar being largely one of degree, it is reasonable to suppose that

such substances as stubble, leaves, etc., may also contribute indirectly to the reserves of soil nitrogen. For the successful operation of nitrogen fixation the suitable general soil conditions are, in addition to the supply of some source of energy, a suitable temperature, the presence of phosphates, and a supply of a base such as calcium carbonate. Even under favourable conditions, however, there occurs a period during which adverse processes come into play, and these should be allowed to run to completion before a crop is introduced. Under unfavourable conditions, and particularly during periods of low temperature, these adverse changes may persist without any subsequent soil gains. Thus in the field experiments the only cases where crop increases were obtained were when the sugar was applied in the early autumn for the next year's crop of barley.—W. G.

Nitrification; Influence of potsherds on — in the Indian alluvium. J. N. Sen. J. Agric. Sci., 1918, 9, 32—42.

The results of pot and lysimeter experiments in the field indicate that the admixture of 30% of potsherds with the soil causes a marked increase in the total amount of nitrates found in the percolation water.—W. G.

Soil; Protozoa and the phenomena of reduction in —. C. A. H. von Wolzogen Kühr, jun. Arch. Sulkerind. Ned. Ind., 1917, 1125—1182. Bull. Agric. Intell., 1918, 9, 788—790.

QUANTITATIVE determinations of reduction phenomena in soil include the "reduction-index," i.e., the number of c.c. of $N/10$ permanganate required to oxidise the ferrous iron liberated from 100 grms. of dried soil in a "sulphurous solution," and the "ferro-index," a similar result obtained in an "acetic solution." Soils may be divided into three classes: good soils, showing little reduction and containing few protozoa, less than 50 per grm.; bad soils, with a high reduction-index and many protozoa, over 50 per grm.; very bad soils, with a very high reduction-index and few protozoa. As protozoa are aerobic, their number increases during the first stages of reduction when they feed on the anaerobes; as reduction continues, the air decreases and the development of the protozoa is checked; finally, the activity of the anaerobes increases to such an extent that the protozoa decrease and die. Butyric fermentation is especially fatal to protozoa. Sulphate reduction is not so injurious, as the hydrogen sulphide produced combines with the iron present. The examination of a large number of soils from sugar-cane plantations in Java showed that there was a relation between the water content, the reduction-index, the ferro-index, and the number of protozoa.

—J. H. J.

"Soil sicknesses"; Researches on certain —. N. L. Sölmgren, A. Kuetemann, and K. T. Wieringa. Verslag. van Landbouwk. Onderzoek. der Rykslandbouwproefstat., 1917, 21, 121—165. Bull. Agric. Intell., 1918, 9, 659—662.

AN investigation of the soil conditions favouring the appearance of "haverziekte" (oat disease) and "Hooghalensche ziekte" (Hooghalen disease) which have appeared recently in the Netherlands and Germany. The first is attributed to an excess of bases in the soil, and the second to excessive soil acidity. The direct and immediate cause of the appearance of these "soil sicknesses" has not yet been determined, but a close relationship has been established between their appearance and the free humic acid content of the soil, thus enabling the soil to be rendered healthy by means of suitable

treatment. Two methods for the determination of the content of free and combined humic acid and the lime requirement of a soil are described, namely, (a) by means of cultures of *Azotobacter*, and (b) by the aid of a diffusion method on agar plates stained by indicators. In method (a) 50 c.c. of distilled water, 2% of mannitol, 0.2% of dipotassium phosphate, and 5 grms. of soil are placed in each of two conical flasks, the mixture is inoculated with *Azotobacter* and incubated at 26° C. A control flask receives in addition some calcium carbonate. The soil is said to be basic or acid according as the bacteria do or do not grow in the flask without calcium carbonate, and it was found that soils causing the oat disease did not favour the growth of the bacteria, whilst soils affected with Hooghalen disease did favour their growth. To determine the lime requirement of the soil two species of *Azotobacter* were used, *A. vinelandii* and *A. chroococcum*, the former being able to grow at a slightly higher degree of acidity than the latter. The lime requirement of a soil was taken as that amount which just suffices for the growth of *A. vinelandii*, but is insufficient for *A. chroococcum*. The results by this method agree quite well with those obtained by the diffusion method. This latter method is based on the fact that acids and bases, even when difficultly soluble, diffuse in a hydrogel. In a layer of agar coloured by litmus, small cavities are made without piercing the layer, and it is found that acids or alkalis placed in these cavities develop a surrounding zone of acid or alkaline reaction in the agar, and this effect is perceptible down to a dilution of $N/5000$. In the determination of the free humic acid content of a soil, 10-grm. portions of soil are heated for three hours at 100° C. with increasing quantities (5 mgrms. at a time) of calcium carbonate, and their reaction is then tested on the agar plate, the results for the soil being expressed in mgrms. of calcium carbonate on the soil or on its loss on ignition. For the determination of total humic acid content (free and combined), the soil is boiled with $N/10$ hydrochloric acid, filtered, and washed free of chlorine, and then the total humic acid is titrated by the agar plate method. For the determination of excess of alkali in a soil, increasing amounts of hydrochloric acid instead of calcium carbonate are added to 10-grm. portions of the soil and the process continued as above. From the results of a large number of analyses the authors find that for any soil, whether sand or peat, acid, neutral or alkaline, the total humic acid per grm. of loss on ignition is always constant and equivalent to about 80 mgrms. of calcium carbonate. They have determined the ratio of free humic acid: combined humic acid, and state that if this ratio is greater than 0.6 the soil is "hyper-acid"; if it is between 0 and 0.5 the soil is healthy, the best percentage of free humic acid being 25% of the total. The content of free humic acid is increased by the application of such salts as potassium chloride, magnesium chloride, and ammonium sulphate, and decreased by the addition of lime, magnesium or sodium carbonates, and sodium nitrate.—W. G.

Bacterio-toxins in the soil; Non-persistence of —. H. B. Hutchinson and A. C. Thaysen. J. Agric. Sci., 1918, 9, 43—62.

SEVEN English soils were examined in order to ascertain whether partial sterilisation effects are due to the destruction of bacterio-toxins in the soils. The test organism used was *B. prodigiosus* and the untreated extracts made by means of 0.8% salt solution varied largely in their suitability for the growth of this organism. Treatment of the extracts by heat invariably led to bacterial decreases, contrary to the results of Greig Smith

(Proc. Linn. Soc. N.S.W., 1910, 25, 808—822; 1911, 26, 679—699; Cent. Bakt. Par. ii., 1911, 30, 154—156), who stated that the toxins are destroyed by heat. Extracts of soils treated with antiseptics (which are not supposed to destroy toxins) were on the whole more favourable for growth than those of untreated soils and were found to contain more organic nitrogen than the latter. Unsuitable extracts could be converted into favourable media by the addition of minute quantities (6 parts nitrogen per million) of peptone. Similar tests with a common soil organism, *B. fluorescens liquefaciens*, gave no evidence of toxicity. The decreases in bacterial numbers in poor, untreated soil extracts are symptomatic of starvation. These results are opposed to Greig Smith's views (*loc. cit.*) and only one soil, an acid heath soil, gave extracts at all similar to those reported by him. The value of the extract from this soil was distinctly increased by heating it to 94° C. for one hour, which process at the same time caused the precipitation of acid iron and alumina compounds removed from the soil by the action of the saline solution. The "toxicity" of this soil can be effectively removed within twenty-four hours by treatment with calcium carbonate. Although it is possible, under well-defined conditions, to induce the formation of bacterio-toxins in culture solutions, there is no evidence to show that these are likely to possess importance in the phenomena of partial sterilisation of soil.—W. G.

Saline soils and their improvement. K. K. Gedroie. Reprint, pp. 1—16.

THE author describes the treatment necessary for the improvement of soils containing excess of neutral salts, such as the so-called white alkali land, and those containing soda, such as the black alkali land.—T. H. P.

Soil; Absorptive power and zeolitic bases of —. K. K. Gedroie. Reprint, pp. 1—55.

EXPERIMENTS have been made on the displacement of the zeolitic bases of a soil by other bases, this being effected by repeated treatment of the soil with solutions of one or more chlorides of N/5, N/1, and 4N concentrations.—T. H. P.

Salt requirements for young and for mature buckwheat plants in solution cultures; Comparative study of —. J. W. Shive and W. H. Martin. J. Agric. Res., 1918, 14, 151—175.

THE culture solutions used were thirty-six different sets of salt proportions of the three salts potassium phosphate, calcium nitrate, and magnesium sulphate, the total initial osmotic concentration in each case being equal to 1.75 atmos. In a period of four weeks directly following germination the highest yield of buckwheat tops and roots was obtained in solutions containing the following salt proportions: $\text{K}_2\text{H}_2\text{PO}_4$ 0.0144 m., $\text{Ca}(\text{NO}_3)_2$ 0.0052 m., and MgSO_4 0.0200 m. During the second four weeks (including the period of seed production and ripening) the highest yield was obtained in a solution containing $\text{K}_2\text{H}_2\text{PO}_4$ 0.0108 m., $\text{Ca}(\text{NO}_3)_2$ 0.0130 m., MgSO_4 0.0100 m. The amounts of water lost by transpiration in each of the two periods of differing development indicate in a general way the yields of tops. There is no definite correlation between the yields of tops and of seeds, such as there is between the yields of tops and of roots.—W. G.

Carbon dioxide; Reduction of — by hydrogen peroxide as the basis of assimilation by plants. H. Wislicenus. Ber., 1918, 51, 942—965.

HYDROGEN peroxide is always at the disposal of the green plant, and the author regards this as the

agent which causes the first stage in the reduction of carbonic acid, namely to formic acid. The carbonate anions are supposed to have peroxide structures, and consequently the reaction is a mutual de-oxidation of two peroxides and requires no expenditure of energy. The process can be tested, for example, with solutions of potassium bicarbonate and hydrogen peroxide, in which case the following equation is given:

(See further, J. Chem. Soc., 1918, i., 472.)—J. C. W.

Plant; Direct influence of the sap of the wild on the cultivated —, and the action of acid solutions, directly absorbed, on the plant. C. Campbell. Atti R. Accad. Lincei, 1918, 27, I., 57—61.

ACCORDING to Comes, the greater resistance normally exhibited by wild plants when compared with cultivated ones is due to the greater acidity of the juices of the former. In this connection the author has made some preliminary experiments to ascertain the influence exerted on a cultivated stock by a wild graft and the effect on plants of the direct absorption of acid solutions.—T. H. P.

Plants; Influence of organic substances on the development of —. H. G. Ciamician and C. Ravenna. Atti R. Accad. Lincei, 1918, 27, I., 38—42.

FURTHER experiments have been made to ascertain the effect of a number of organic compounds on the germination of the seeds and the development of the plants of beans, maize, tobacco, beetroot, and lupins. (See J. Chem. Soc., 1918, i. 473.)—T. H. P.

Nitrogenous refuse [leather and horn waste, etc.]; Utilisation of —. E. Donath and G. Ulrich. Oesterr. Chem.-Zeit., 1917, 20, 165—168. Z. angew. Chem., 1918, 31, Ref., 218.

REFUSE, rich in nitrogenous matter, is heated with waste sulphuric acid; a portion of the nitrogen is thus converted into ammonium sulphate and the remainder is obtained in the form of a highly nitrogenous charcoal. Products which are practically dry, and rich in ammonium sulphate, are obtained by heating for several hours at over 240° C. Chamber acid or waste sulphuric acid may be used. If larger proportions of acid are employed, pasty products are obtained from which fertiliser mixtures may be prepared by combining them with ground limestone or phosphate. The yield of ammonium sulphate may be increased by carrying out the destruction in the presence of certain catalytic agents, preferably at 250°—270° C.—J. F. B.

XVII.—SUGARS ; STARCHES ; GUMS.

Law of action of sucrose [invertase]; hypothesis of an intermediate compound. Colin and Chandun. See XVIII.

Utilisation of rice and its by-products. See XIXA.

PATENTS.

Carbons; Decolorising — and process of producing the same. H. M. Shilstone, New Orleans, U.S.A. Eng. Pat. 116,253, July 26, 1917. (Appl. No. 10,759 of 1917.) Under Int. Conv., May 31, 1917.

RICE hulls, rice straw, or rice chaff, or other cereal fibrous material rich in silica, is carbonised and then heated with an alkaline solution to extract any resinous or other soluble matters. The material may first be heated gradually, to vaporise volatile resins, the temperature being subsequently raised for carbonisation; the ground product is then boiled with alkali, preferably with 20% of its weight of sodium hydroxide, and after washing with water it may be extracted with acid. The use of carbons prepared by this process for the decolorisation of, and removal of tannins from, saccharine liquids, e.g., sugar cane juice, is also claimed.—J. H. L.

Carbon; Process of manufacturing decolorising —. The Ensuiko Seitō Takushoku Kabushiki Kaisha, Y. Okada, and H. Miyake, Shimeisho, Japan. Eng. Pat. 117,828, June 27, 1917. (Appl. No. 9248 of 1917.)

Fatsia papyrifera, cane megasse, or any grass found in fresh or sea water, is boiled with a solution of calcium hydroxide, and after the latter has been removed by washing, the material is carbonised, preferably in an iron retort at 750°—800°C. The product may subsequently be extracted with acid.—J. H. L.

Adhesive [from starch]. C. R. Robinson, Assignor to Perkins Glue Co. U.S. Pat. 1,267,699, May 28, 1918. Date of appl., Mar. 13, 1916.

DRY starch is treated with sodium bisulphate (1%) and sodium hydroxide (6%), and then mixed with trisodium phosphate (1%) and water (6%), with or without ammonia. The mixture is cooked to render the starch soluble, and then neutralised and treated with cupraammonium sulphate (1%), with or without casein. Adhesive or coating preparations are claimed consisting of soluble starch, water, and a waterproofing material, with or without casein.

—J. H. L.

Glue; Process of manufacturing vegetable — [from starch]. V. G. Bloede, Catonsville, Md. U.S. Pat. 1,269,678, June 18, 1918. Date of appl., Oct. 10, 1917.

A CLEAR viscous liquid is prepared from starch by the action of a caustic alkali and water, and the alkali is then completely or partly neutralised by injection of acid in vapour form.—J. H. L.

Starch; Method of producing dustless —. A. W. H. Lenders, Cedar Rapids, Iowa. U.S. Pat. 1,272,682, July 16, 1918. Date of appl., Mar. 30, 1914.

STARCH or other friable material is freed from dust by subjecting it, during its descent through a relatively short, unobstructed chamber, to a series of jets of air at various angles, the separated dust being carried by a current of air away from the field of the jets and the region of delivery of the treated starch.—J. H. L.

Fuel from waste material and making and utilising the same. Eng. Pat. 117,921. See IIA.

XVIII.—FERMENTATION INDUSTRIES.

Wine; Fixed organic acids, especially lactic acid, in [Tuscan]. G. de Astis, Annali Chim. Appl., 1918, 9, 155—211.

MOESLINGER'S method of determining lactic acid in wine (precipitation as barium lactate) usually gives results from 0.1 to 0.2 gram. per litre too high, owing to the influence of tartaric, malic, citric, or succinic acids, but in the case of wines from grapes grown on calcareous soils, or which from their treatment contain a considerable amount of calcium malate, the error may be as high as 0.75 gram. per litre. The addition of sulphur dioxide (5 to 8 grms. per litre) to Tuscan grape juice retarded for a few days the beginning of fermentation, but then accelerated its course and increased the yield of alcohol by 0.1 to 0.5 gram. per litre. It reduced the loss of fixed organic acids, but this effect was lessened or inhibited by the presence of grape stalks during the fermentation. The quantity of fixed and volatile acids produced during fermentation of Tuscan wines fluctuates between 20 and 50 c.c. of N/1 acid per litre (1.80 to 4.20 grms. of tartaric acidity), and is composed mainly of lactic acid (5 to 11 c.c. of N/1 acid), succinic acid (11 to 19 c.c.), and volatile acids (8 to 20 c.c.). The loss of acidity in the course of a year during the conversion of must into wine may vary from 14 to 134 c.c. of N/1 acid (1 to 10 grms. as tartaric acid per litre). The addition of citric, malic, or succinic acid to grape must causes an irregular increase in the amounts of glycerol, extract, ash, and alkalinity of ash of the wine, whilst tartaric acid has the opposite effect. In the case of Tuscan wines it is the usual practice to ferment the must in such a way as to reduce the fixed acidity and to increase the volatile acidity by 0.1 to 0.4 gram. (as acetic acid) per litre. In these wines the free and combined tartaric acid varies from 1.5 to 5 grms. per litre, and rarely exceeds the higher limit. Tartaric acid does not contribute to the formation of lactic acid in the wine, but even checks the formation if present in quantities of 0.2% and over. The tartaric acid in Tuscan wines may amount to as much as 86% of the total fixed acidity. The amount of malic acid in Tuscan grape musts varies as much as the tartaric acid, over which it predominates only in unripe grapes. It is exceedingly soluble in wine, and is readily destroyed by fermentation and by bacteria. Free malic acid in wine does not undergo the malolactic fermentation, but in the form of calcium malate

is rapidly transformed into lactic acid both by yeasts and bacteria. Malic acid added to wine in the proportion of 0.5 to 1.5% increases the fixed acidity and the extract, but may totally disappear during the maturing of the wine, without producing lactic acid. The amount of succinic acid in Tuscan wines varies from about 0.65 to 1.20 gm. per litre; it is formed as a metabolic product of the yeast during the fermentation of the must. It exists for the most part in the free state in the wine, though it tends to form soluble salts. When added to grape must it may be transformed by specific bacteria into lactic acid, even in the presence of sulphur dioxide. Citric acid is present in traces in the grape must and is not produced during fermentation. When added to the must or the wine it comes next to tartaric and succinic acids in its resistance to micro-organisms. It remains largely unaltered in wines containing sulphur dioxide, but in the absence of sulphites is destroyed by bacteria. It does not contribute to the production of lactic acid, but checks the production when present in quantities of about 0.2%. The addition of citric acid to grape must increases the solubility of tartaric acid in the wine, and causes an increase in the amounts of glycerol, extract, ash, and alkalinity of the ash. In practice citric acid is added in association with sulphur dioxide to maintain the acidity of the wine during and after fermentation. Tuscan wines contain from 0.5 to 4 grms. of lactic acid per litre, corresponding to 4 to 49% of the fixed acidity. The larger quantities are due to abnormal fermentation of the sugar, or to bacterial fermentation of the malic and succinic acids and probably also of the glycerol. Neutralisation of part of the acidity of the grape must by means of calcium carbonate promotes the rapid production of lactic acid. Wines containing 1% of total acidity rarely undergo lactic fermentation. The method of fermentation used for Tuscan wines accelerates and increases the production of lactic acid by 0.1 to 0.9 gm. per litre. As the wine matures there is a gradual decomposition of the lactic acid, 50% of which may disappear within a year. Wines rich in alcohol (12% or more) are usually poorer in lactic acid than wines of lower alcoholic strength.—C. A. M.

Sucrase [invertase]; Law of action of —; hypothesis of an intermediate compound. H. Colin and A. Chaudun. *Comptes rend.*, 1918, **167**, 338—341.

THE results obtained in the hydrolysis of sucrose by varying the relative proportions of sucrose and sucrase are in agreement with Brown's hypothesis (this J., 1902, 419) of the formation of a compound between the sugar and the enzyme. (See further *J. Chem. Soc.*, Oct., 1918.)—W. G.

Utilisation of rice and its by-products. See XIXA.

Yeast; Method of treating brewers' — to render it suitable for baking purposes. H. W. Anderson, Exeter, W. Lambhead, Paignton, W. Lambhead, jun., Exeter, and J. M. Ramsay, Kilmarnock, Ayrshire. Eng. Pat. 117,666, July 24, 1917. (Appl. No. 10,632 of 1917.)

BREWERS' yeast is treated first with an aqueous solution of borax and an alkali carbonate, and subsequently with a solution of alkali carbonate alone. For example, 25 galls. of yeast, mixed with 60 galls. of water, is sifted and left to stand; after removal of the water the yeast is stirred for about 15 mins.

with 50 galls. of water containing 3 lb. of borax and 10 oz. of sodium bicarbonate and allowed to subside. The liquid is then drawn off and the yeast stirred for 20—30 mins. with 60 galls. of water containing 7 oz. of potassium carbonate or an equivalent amount of other alkali carbonate.—J. H. L.

Yeast; Preparation of —. L. Roush, Beaver, Pa. U.S. Pat. 1,271,371, July 2, 1918. Date of appl., Apr. 5, 1917.

YEAST is stimulated by growth in a fluid culture mass into which air is caused to penetrate through a porous body; *e.g.*, pressed yeast is invigorated by introducing it into a wort prepared from malt flour, malt combs, and flour, and allowing air to penetrate through a porous body into the wort.

—J. H. L.

Wort and other liquids; Aeration and carbonisation of — in connection with counter-current surface cooling apparatus. P. Robinson, Burton-on-Trent. Eng. Pat. 117,911, May 25, 1917. (Appl. No. 7514 of 1917.)

IN apparatus such as those used for cooling and aerating wort or carbonating beer, in which the liquid and gas are together passed through a tubular system subjected to external counter-current cooling, claim is made to two devices, one connected with the inlet and the other with the outlet of the tubular system. The former consists of a small chamber through which the liquid passes and into which air or gas is injected through minute orifices in the ends of one or more tubes projecting into the chamber. The latter consists of a small chamber the lower part of which is filled with the wort issuing from the tubular system, and this liquid supports a float actuating a snift valve which controls the pressure of air or gas in the liquid by allowing it to blow-off whenever the pressure exceeds the desired value.—J. H. L.

Grain; Process of treating — for beverages. B. Leibbrandt, Santa Cruz, Cal. U.S. Pat. 1,269,100, June 11, 1918. Date of appl., Nov. 12, 1917.

WHEAT in the form of whole grains is first softened at about 80° F. (27° C.) until germination commences, next moistened and subjected to a "cooking heat" for about 6 hours until it becomes mellow, then dried by gentle heat, and finally roasted.

—J. H. L.

Sulphite [cellulose] liquor; Process of fermenting —. A. Lackman, New York. U.S. Pat. 1,269,287, June 11, 1918. Date of appl., Feb. 26, 1912.

THE waste sulphite liquor is brought to the boil and a quantity of sulphuric acid, *e.g.*, about 0.2%, substantially equivalent to the sulphur dioxide and sulphites present, is added to the hot liquor; the sulphur dioxide liberated is removed in the gaseous form, and the acidified liquor is cooled and fermented.—J. F. B.

Sulphite [cellulose] liquors; Process of obtaining alcohol from —. R. H. McKee, Ridgefield Park, N.J. U.S. Pat. 1,273,392, July 23, 1918. Date of appl., Aug. 27, 1917.

YEAST is added to sulphite liquor containing an appreciable amount of free sulphurous acid, the solution being aerated substantially throughout the fermentation, thereby maintaining the fermentative action; alcohol vapours are recovered from the exit gases by scrubbing them with unfermented liquor.—J. F. B.

Distilling liquid mixtures or [alcoholic] solutions; Method of —. H. O. V. Bergström, Stockholm, Sweden. U.S. Pat. 1,271,654, July 9, 1918. Date of appl., Jan. 8, 1917.

Is the recovery of relatively small proportions of alcohol from an aqueous liquid, the latter, suitably preheated, is introduced into a column still at a point above the lower de-alcoholising portion, in which it is boiled by injection of steam. The alcoholic vapours produced, after mounting through the upper dephlegmating portion of the column, yield their heat (in a tubular cooler) to a cooling liquid (water) which, being maintained under a relatively low pressure, becomes vaporised and thus yields a useful quantity of steam.—J. H. L.

Beverages; Process of stabilising temperance cereal —. C. S. Ash, Assignor to Gould and Ash, San Francisco, Cal. U.S. Pat. 1,271,991, July 9, 1918. Date of appl., Nov. 15, 1917.

The beverages are rendered chill-proof and capable of undergoing pasteurisation without deterioration of flavour by treating them, at any stage of their manufacture, with tannin and sulphurous acid or its salts, and removing the precipitate formed thereby. (Cp. U.S. Pat. 1,231,255; this J., 1917, 1059.)—J. H. L.

Vinegar-making; Process of —. Apparatus for vinegar-making. E. Klein, Peekskill, N.Y. U.S. Pats. (A) 1,272,276 and (B) 1,272,277, July 9, 1918. Date of appl., Jan. 12, 1916.

(A) The vapours escaping with the spent air from an acetifier working on the Schutzenbach principle are condensed by means of the incoming gyle, which has previously been cooled, and the mixture is then subjected to the action of fresh air. (B) An acetifier is divided by a number of false bottoms into a vertical series of compartments, these false bottoms consisting of strips with spaces between. Means are provided for cooling the gyle, and for making air rise through the false bottoms at a temperature automatically maintained below a predetermined maximum.—C. A. M.

Alcohol; Process for the manufacture of — from grain in open vats with the employment of saccharifying mucors. H. Boulard, Paris U.S. Pat. 1,266,657, May 21, 1918. Date of appl., Dec. 7, 1916.

See Eng. Pat. 102,945 of 1916; this J., 1918, 525 A.

Bread-making process. U.S. Pat. 1,239,754. See XIXA.

XIXA.—FOODS.

Wheat, flour, etc.; Determination of the non-digestible residue in — by means of pancreatin. L. Devillers. J. Pharm. Chim., 1918, 13, 5—12.

Five grms. of the wheat (whole grains) is placed in a thick-walled stoppered flask and covered with N/5 sodium borate solution (38.20 grms. per litre) diluted with three times its volume of water. The flask is immersed in water at 55° C. for 12 hrs., the contents then shaken, the grains collected on a sieve, washed with warm water, returned to the flask, and again heated at 55° C. with 25 c.c. of N/5 sodium borate solution, 3 c.c. of N/1 calcium chloride solution, 2.5 c.c. of 1% pancreatin solution (in chloroform water), and sufficient water to make the volume up to 100 c.c. The mixture is stirred until the grains are disintegrated

(this requires from 1 to 2 hrs.), the flask is then closed securely and heated, first at 75° C. for 30 mins., and then in an autoclave at 120° C. for 15 mins. After cooling to 55° C., 2.5 c.c. of the pancreatin solution is added, and the mixture maintained at 55° C. until all the starch has been hydrolysed (iodine test). Ten c.c. of N/1 hydrochloric acid is then added, the heating at 55° C. continued for 1 hr., and the insoluble residue collected, dried, and weighed. Wheat yields from 9.9 to 11.5% of insoluble matter (calculated on the dry substance), flours 4.8 to 8.2%, bread 7.5%, and bran 35.2%.—W. P. S.

Maize protein; Efficiency of — in adult human nutrition. H. C. Sherman and J. C. Winters. J. Biol. Chem., 1918, 35, 301—311.

FEEDING experiments with maize on a young woman are described, which show that nitrogenous equilibrium can be maintained over long periods with a protein intake considerably below that of the Chittenden standard, and of which very much the largest part may be maize protein. This indicates that the protein in maize is sufficient to maintain life even in the case of a low protein diet. Ordinarily, therefore, the substitution of maize products for those of wheat is physiologically justified.—H. W. B.

Rice and its by-products; Utilisation of —. Bull. Imp. Inst., 1918, 16, 16—24.

A NUMBER of samples of Burmese rice have been examined, classified, and analysed, all of which would be suitable for starch manufacture and brewing. In these industries the broken grains are employed, and it is not considered advisable to grow special varieties for the purpose. For starch manufacture a rice of medium hardness with low protein content is preferred. The variation in the percentage of starch is not large, and this percentage is not necessarily an index of the manufacturing yield; variations in the fat content have no influence. "Red skin" is objectionable, as it gives a dark solution when the grain is softened by alkali. Yellowness of the grain, generally caused by heating in transit, is also objectionable. Fully matured rice is preferred as being freer from undersized granules. For brewing, rices with a minimum fat-content and maximum percentage of starch give the best results. *Rice straw for paper-making.* A sample of Egyptian rice-straw has been tested, containing moisture, 11.8; ash, 17.6; cellulose, 50%. The length of the ultimate fibres was 0.6—3.0 mm.; mostly 0.9—1.3 mm. On digestion for 4 hours at 140° C. with 14% of caustic soda the yield of dry pulp was 41%; with 10% of soda, 50%; and with 8% of soda, 52%, all expressed as dry pulp on air dry straw. These pulps all bleached easily to a pale cream colour, almost white. On digestion for 12 hours at 140° C. with 20% of lime, the straw yielded 56% of yellow straw pulp suitable for boards and brown papers. The above experiments showed that a good bleaching pulp could be obtained with an unusually small consumption of soda, but this advantage is partly counterbalanced by losses in the recovery of soda from a material containing such a large proportion of silica. *Rice husks.* The sample examined contained on the dry substance 14.7% of ash and 42% of cellulose; the fibres varied in length from 0.5 to 1.5 mm., being mostly 0.5—0.7 mm. When digested for 4½ hours at 140° C. with 16% of caustic soda, the husks yielded 36% of dry pulp on the air dry weight. The pulp contained a large proportion of gelatinous material and could not be bleached satisfactorily. It gave a very weak and brittle paper, and could not be used in paper-making except as a filler in admixture with pulps of longer fibre.—J. F. B.

Milk; Correlation between the percentage of fat in cow's — and the yield. E. Roberts. J. Agric. Res., 1918, 14, 67—96.

THE results of a statistical investigation into the relation between quality and yield of cow's milk are given in the case of American cattle. The breeds studied were Jerseys, Guernseys, Ayrshires, Holstein-Friesians, and unclassified cows. It was found that the yield of milk increased with age up to 5 years (cows over 5 were classed with those of 5). The percentage of fat remained constant, except for the Ayrshires, where there was a decrease with age. Breed had an influence on the variability of the two factors: for variability in yield the order was Holsteins, Ayrshires and Guernseys equal, Jerseys; for variability in fat the order was Jerseys, Guernseys, Ayrshires and Holsteins equal. The total yearly yields were: Holsteins, 14,443 lb.; Ayrshires, 9417 lb.; Guernseys, 8644 lb.; Jerseys, 7491 lb.; unclassified, 5824 lb. The average percentages of fat were: Jerseys, 5.39; Guernseys, 5.03; Ayrshires, 3.93; unclassified, 3.90; Holsteins, 3.43.—J. H. J.

Milk; Effect of heat on the citric acid content of —. Isolation of citric acid from milk. H. H. Sommer and E. B. Hart. J. Biol. Chem., 1918, 35, 313—318.

MILK contains about 0.2% of citric acid. The content of citric acid is not affected by heating the milk. The anti-scorbutic property of milk, which is lost by heating, cannot therefore be associated with its content of citric acid. (See further J. Chem. Soc., 1918, i., 465.)—H. W. B.

Chymosin (rennet) and pepsin; Action of —. IV. Action of the enzymes on sodium caseinogenate. O. Hammarsten. Z. physiol. Chem., 1918, 102, 32—77.

THE differences in the action of two extracts of gastric mucous membrane containing pepsin and rennet on milk and on fibrin or white of egg are exactly paralleled by their action on sodium caseinogenate in alkaline and acid solution respectively. Thus, if one extract shows relatively greater clotting than digesting power when tested on milk and on fibrin, then it is found that its action on sodium caseinogenate is more marked in alkaline than in acid solution. These facts support the hypothesis which regards rennet and pepsin as two distinct enzymes.—H. W. B.

Fruit juices [raspberry and apple]; Examination of —. F. Härtel and J. Söiling. Z. Unters. Nahr. Genussm., 1918, 35, 437—442.

SIX samples of raspberry juice, which had been fermented in the presence of the fruit, then expressed, and filtered, yielded the following results on analysis:—Sp. gr., 1.0139 to 1.0171; alcohol, 1.96 to 3.48; total solids, 3.48 to 5.15; acidity, 1.46 to 2.19; sucrose, none; invert sugar, 0.09 to 0.40; ash, 0.44 to 0.71 gm. per 100 c.c.; alkalinity value, 10.50 to 12.17. A raspberry juice expressed directly had sp. gr. 1.0361; alcohol, none; total solids, 8.48; acidity, 1.17; sucrose, 0.034; invert sugar, 5.54; ash, 0.49 gm. per 100 c.c.; alkalinity value, 10.09. Analyses are also given of 24 raspberry juices which had been treated with various preservatives, kept for 1 year, and then examined. Salicylic acid (1 gm. per litre) gave the best results, then followed hydrofluoric acid (0.5 gm. per litre), benzoic acid (1.5 gm. per litre), and formic acid (2.5 gms. per litre). Seven of the samples had decomposed in spite of the presence of preservative, and four of these had been preserved with formic acid. A sample of apple juice was also examined, the first, last, and main runnings being analysed separately to see whether there was any difference in these portions of the juice; no differ-

ence was found. The results for the main runnings were:—Sp. gr., 1.0503; alcohol, none; total solids, 12.48; acidity, 0.66; sucrose, 1.76; invert sugar, 8.02; ash, 0.28.—W. P. S.

Sudan-grass hay; Composition and digestibility of —. W. G. Gaessler and A. C. McCandlish. J. Agric. Res., 1918, 14, 176—185.

THE dry matter of Sudan-grass (*Andropogon sorghum*) hay changes slightly in composition from the time of heading until the crop is ripe. The protein and fat content increase in the early stages of ripening and then decrease, whilst the changes in the nitrogen-free extract (carbohydrates) and ash content are in the opposite direction. There is very little change in the fibre content of the dry matter from the time the Sudan grass heads out until it is fully ripe. Either as a green feed or as hay Sudan grass is very palatable, and the hay has a comparatively high apparent digestibility, the coefficients of digestibility, as determined with two heifers a year and a half old, being dry matter 64.9%, protein 47.4%, nitrogen-free extract 67.8%, fibre 70.6%, ether extract 58.4%. Sudan-grass hay supplies energy to cattle much more efficiently than it does protein as compared with hay from timothy or millet.—W. G.

Rape straw as a paper and fodder material.* Heuser and Blasweiler. See V.

Cephalin. V. Hyarocephalin of the egg yolk. Levene and West. See XX.

Erratum

Detection of cane sugar in milk. G. D. Elsdon (see this J., 1918, 558A). In lines 4 and 5 of abstract read "3N hydrochloric acid," and for "0.1 gm. of resorcinol" read "0.5 gm."

PATENTS.

Dry milk or milk-powder; Impts. in, and apparatus for, the production of —. R. R. F. Butler. Devices. Eng. Pat. 117,713, Aug. 23, 1917. (Appl. No. 12,130 of 1917.)

IN apparatus in which milk is dried on heated cylinders, the milk is kept cool, up to the moment when it comes into contact with the heated cylinder, by circulating cold brine through a jacket surrounding the containing tray and also through the feed rollers.—W. P. S.

Emulsifying apparatus [for milk]. J. T. Davis. Alameda, Cal., Assignor to J. Rothschild, San Francisco, Cal. U.S. Pat. 1,269,399, June 11, 1918. Date of appl., July 13, 1917.

AN apparatus for emulsifying milk consists of two discs having on their adjacent surfaces a series of concentric circular grooves, the grooves of one disc being eccentric to those of the other; means are provided for revolving the discs and pressing them together.—W. P. S.

Butter substitutes and the like and the preparation of same. J. J. A. Talbot, Southsea. Eng. Pat. 118,215, Dec. 13, 1917. (Appl. No. 18,546 of 1917.)

WASTE fat and meat are cut up and shredded and slowly melted, with or without the addition of chopped marrow or other bones, at about 42° C., the material being clarified by the addition of salt at intervals. The melted fat is strained from unmelting particles and impurities and poured into a mixing vessel where it is churned with milk and a binding agent such as white of egg or dried blood. The melting process may be accelerated and

coagulation of the fat on the sides of the melting vessel prevented by the use of a wooden plunger or other squeezing device.—C. A. M.

Milk-food product and method of making the same. W. P. M. Grelek, Lincoln, Nebr. U.S. Pat. 1,272,035, July 9, 1918. Date of appl., Dec. 26, 1916.

A PASTEURISED acid milk food product is prepared by subjecting soured milk to the action of a jet of steam whereby the casein is precipitated and when shaken is obtained in the form of minute, mutually non-adherent particles. These particles may be mixed with extract of malt, and the excess fluid removed.—W. G.

Prepared food. Vegetable milk. A. S. Burdick and C. Nielsen, Assignors to The Abbott Laboratories, Chicago, Ill. U.S. Pats. (A) 1,273,144 and (B) 1,273,145, July 23, 1918. Date of appl., July 13, 1917.

(A) Soy beans are soaked in water, the water drained off, the beans mashed, and the mash extracted with water. The extract is mechanically separated from the residue, filtered, mixed with a cereal flour gruel which has been malted to produce a syrupy liquid containing dextrins and sugar, and salts as contained in body tissues are added in the desired proportions. (B) Grain is soaked in water, the water drained off, the residual grain mashed, the mash extracted with water, and the extract separated from the unextracted residue.—C. A. M.

Dietetic food; Apparatus for the production of — and for obtaining fat from animal carcasses and refuse. G. Zwicky, Geneva, Switzerland. Eng. Pat. 117,852, Aug. 7, 1917. (Appl. No. 11,336 of 1917.)

THE material is disintegrated by heating it under pressure in a steam-jacketed vessel provided with a stirrer; the separated fat is then removed from the surface of the mass, and the latter is dried by stirring it, while hot compressed air is forced through it. The air inlets are at the bottom of the vessel, both at the circumference and at the centre. The dried material is discharged through an opening at the bottom of the vessel.—W. P. S.

Flour; Treating —. H. Greville, Birkenhead. Eng. Pat. 117,917, June 28, 1917. (Appl. No. 9274 of 1917.)

IN order to give a greater body and improved pile to the bread from weak or medium wheat mixtures, the sulphates or acid sulphates of sodium, potassium, or ammonium either singly or conjointly, or mixed with other substances, are mixed in powdered or granular form with the flour at the rate of 1—2 oz. per sack of 250 lb. of flour, the exact amount to be added to a particular flour being ascertained by trial bakings.—W. G.

Bread-making process. F. P. Siebel, Assignor to Siebel Institute of Technology, Chicago. U.S. Pat. 1,269,751, June 18, 1918. Date of appl., Feb. 15, 1918.

A MASH prepared with malt and water is saccharified, the wort is separated, cooled, mixed with yeast, and, when fermentation has commenced, the mixture is added to the dough. A dough for bread making is prepared from "brewers' grains" in place of other flour, and a fermenting wort in place of ordinary sugar.—W. P. S.

Food; Prepared — and process for making the same. X. Kuzmiler, Hartsdale, N.Y. U.S. Pat. 1,273,072, July 16, 1918. Date of appl., May 7, 1918.

FOOD is cooked with a liquid until practically all the soluble constituents are dissolved out. The solid portion is then removed and dried, and the solution is evaporated to a volume such as will be absorbed by the solid portion, with which it is then mixed, any necessary flavouring being added, and the whole heated at 160°—210° F. (71°—99° C.) for a time sufficient to sterilise it and dry it without overcooking. The product is packed in moisture-proof containers.—W. G.

Milk product; Desiccated — and process and apparatus for manufacturing it. C. H. Campbell, New York. Eng. Pat. 117,276, Apr. 5, 1917. (Appl. No. 4967 of 1917.)

SEE U.S. Pat. 1,233,446 of 1917; this J., 1917, 1025.

Method of treating brewers' yeast to render it suitable for baking purposes. Eng. Pat. 117,666. See XVIII.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Bacteriological examination of —. Detection of indole-forming bacteria by the bile-dextrose and phenol methods. L. Bourdet. J. Pharm. Chim., 1918, 18, 42—46.

COMPARISON of the bile-dextrose method proposed by Grysez and Pieret (Presse Med., Oct., 1917) with the ordinary method showed that the results obtained do not agree well with each other in many cases. Of fifty samples of water tested by the methods, concordant results were obtained in twenty cases only; in the others, higher results were obtained sometimes by the bile-dextrose method and sometimes by the phenol method.

—W. P. S.

Copper; Determination of — in insecticides. G. S. Jamieson. Chem. and Met. Eng., 1918, 19, 185.

FROM 0.2 to 0.5 gm. of the insecticide is moistened with 10 c.c. of water, and 5 c.c. of sulphuric acid (1:3) added. The mixture is then heated, and, when completely decomposed, most of the free acid is neutralised with ammonia. The solution is heated nearly to boiling, and 10 c.c. of sulphurous acid and 5 to 10 c.c. of a 10% solution of thiocyanate added. The precipitate is allowed to settle, filtered off, washed, dissolved in a mixture of 35 c.c. of concentrated hydrochloric acid and 20 c.c. of water, and 7 c.c. of chloroform added. The solution is then titrated with a potassium iodate solution containing 11.784 grms. KIO₃ per litre, each c.c. corresponding to 0.002 gm. of copper. The titration is done in a stoppered bottle which is well shaken after each addition of iodate.—F. C. Th.

PATENTS.

[*Sewage*] *water-purifier. Sewage treatment.* G. Moore, Joplin, Mo., Assignor to The Chemical Process Co., New York. U.S. Pats. 1,271,925 and 1,271,926, July 9, 1918. Date of appl., Oct. 31, 1914.

SEWAGE is passed into a container where it is continuously agitated in presence of previously coagulated sewage solids, and also, if desired, in presence of fuel solids. From this container the sewage is passed into a second container, where the solids

are separated in the lower portion and returned to the first container, whilst the liquid with suspended solids passes away at the top into a third container, where it is filtered or otherwise separated from the suspended solids. The latter may be converted into a fuel.—J. H. J.

Water-softening apparatus. Means for regulating water-softening apparatus. Means for regulating the feed of chemicals in water-softening apparatus. C. L. Kennicott, Chicago Heights, Ill., Assignor to The Permutit Co., New York. U.S. Pats. (A) 1,272,052, (B) 1,272,053, (C) 1,272,054, July 9, 1918. Date of appl., Mar. 20, 1916.

(A) THE apparatus consists of a vertical drum, filled except at the top and bottom with a base-exchanging material. A float lies on the top of the material and actuates an air outlet valve, whereby the water entering at the top may pass down as a solid column through the material at a uniform rate. An outlet for the softened water is provided at the bottom. (B) A portion of the raw water is by-passed into a bucket which floats in a tank and controls the outlet of a chemical tank so as to discharge the chemicals into the main stream of raw water. (C) Means are provided for supplying displacing fluid to the chemical tank in an amount which is regulated by the position of the bucket. An overflow for the chemical tank is provided and means for mixing the liquid overflowing with the main stream of raw water.—J. H. J.

Bacteria destruction by pressure; Method of —. J. R. Witzel, Philadelphia, Pa., Assignor to Food Sterilization Co. U.S. Pat. 1,269,562, June 11, 1918. Date of appl., Jan. 29, 1917.

FLUID containing cell bodies and organisms in suspension is confined in a vessel, which is exhausted to cause an expansion of the cell bodies, and a pressure of about 75,000 to 100,000 lb. per sq. in. is then applied to break down the bodies. The organisms are destroyed and the cell bodies are ruptured or disintegrated, so that the substances are more intimately diffused throughout the containing fluid.—B. N.

[Sewage] sludge; Apparatus for pressing activated —. W. Buckley, Chicago, Ill. U.S. Pat. 1,271,425, July 2, 1918. Date of appl., July 20, 1916.

SLUDGE is automatically delivered at intervals from a container into a vessel from which it is forced into a filter-press, the frequency of the deliveries depending upon the speed of filtration.—C. A. M.

Insecticides. J. F. Moseley and E. McCardell, Manchester. Eng. Pat. 117,916, June 9, 1917. (Appl. No. 8252 of 1917.)

TETRACHLOROETHANE or other halogen-substituted hydrocarbon is mixed with naphthalene, and the resulting solution is emulsified with soap or an alkali salt of a sulphonated fatty acid. The product is miscible with water; it may be mixed with diatomaceous earth to form a dusting powder. An alkali borate or silicate may be incorporated with the soap before emulsification.—J. H. J.

Vermis [rats, mice, etc.]; Substance [3-methylxanthine] for the destruction of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 305,926, Nov. 5, 1915.

3-METHYLBXANTHINE, with or without addition of other substances, can be used for the extermination of vermin without having any harmful effect on human beings and domestic animals.—L. A. C.

Water; Apparatus for the softening and purification of —. J. J. Lassen and V. F. Hjort, London. U.S. Pat. 1,265,346, May 7, 1918. Date of appl., Mar. 12, 1917.

SEE Eng. Pat. 106,514 of 1916; this J., 1917, 905.

Water and other liquids; Treatment of — by ultra-violet rays. V. Henri, A. Helbronner, and M. von Recklinghausen, Paris, Assignors to The R.U.V. Co. U.S. Pat. 1,266,803, May 21, 1918. Date of appl., Oct. 31, 1910. Renewed Aug. 13, 1917.

Process for the separation of grease from wool scouring or like effluents. Eng. Pat. 118,332. See V.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

[Ocimum] oils; Aromatic — from the Seychelles. Bull. Imp. Inst., 1918, 16, 32–35.

Ocimum gratissimum grows as a weed in Mahé (Seychelles); distillation of entire shoots yielded 0.1% of a light brown oil having a pronounced odour of cloves with a peculiar, not very pleasant secondary aroma. The characters of the oil were as follow:—Sp. gr. at 15° C., 0.995; $\alpha_D^{20} = -14.1^\circ$; $n_D^{20} = 1.526$ at 21° C.; soluble in 0.7 vol. of 80% alcohol at 15° C.; phenols, 62%, principally eugenol. This oil from the Seychelles differed completely from an oil stated to be derived from *O. gratissimum* from the Ivory Coast, which contained 41% of phenols, almost entirely thymol. The oil was not sufficiently pleasant in odour to be of use in perfumery, and in view of the small yield of oil the plant would hardly be capable of being utilised to advantage as a source of eugenol. *Ocimum basilicum* (sweet basil) from the Seychelles yielded 0.21% of an oil having the following characters:—Sp. gr. at 15° C., 0.962; $\alpha_D^{20} = +0.82^\circ$ at 28° C.; $n_D^{20} = 1.514$ at 21° C.; acid value, 0.8; ester value, 2.5; nearly soluble in 4 vols. of 80% alcohol but not completely soluble even in 10 vols. These characters agree generally with those of Réunion sweet basil oil. The Seychelles oil appeared to contain anethol as well as methylchavicol. The commercial prospects of this oil are not considered encouraging. —J. F. B.

Ajowan seed and thymol. Bull. Imp. Inst., 1918, 16, 30–32.

AJOWAN seed is derived from an annual herb, *Carum copticum*, closely related to the ordinary caraway. It is grown mostly in India, and the volatile oil of the seeds is used as the principal source of thymol. Samples of seeds from experimental crops grown in the Seychelles and Montserrat have been examined. The Seychelles seed had a poor appearance, a large proportion being small and immature. The seed yielded approximately 9% of oil containing about 28% of thymol; Indian ajowan seed yields only 3–4% of oil containing 40–55% of thymol. Consequently, although the Indian oil is

rieher, the yield of thymol from the Seychelles seed is higher than from Indian seed. The Montserrat seed yielded 3.1% of oil containing 51% of thymol; the oil had sp. gr. 0.925 at 15°/15° C., and $\alpha_D = +0.90^\circ$. The seed was harvested six months after sowing and showed a yield of 1128 lb. per acre. The result is considered to be encouraging, but the distillation of the oil should be carried out in the country of origin.—J. F. B.

Terpenes and essential oils. CXX. O. Wallach, K. Pelikan, H. Berthold, L. Augspurger, H. Worlitzer, and F. Pohle. *Annalen*, 1917, **414**, 195—233.

THE greater part of the work has been already published. The expectation, justified by the accepted formulae of pinol hydrate and dihydrocarveol, that the reduction product of the former will be identical with the menthane-2,8-diol obtained by the addition of water to the latter, is not borne out by experiment: both with the optically active and inactive forms, the products in the two cases are quite dissimilar. When pinol hydrate is reduced by hydrogen and colloidal palladium in the absence of free acid, dehydration occurs to some extent and tetrahydrocarveol is obtained as a by-product. This furnishes a further proof that a hydroxyl group occurs in position 2 in pinol hydrate. Terpinene dihydrobromide is formed by the action of hydrogen bromide in glacial acetic acid on *i* or *l*-dihydropinol hydrate. Dihydropinol hydrate is not identical with menthane-1,4-diol or with menthane-2,4-diol, obtained by reducing sabinene-glycol by Paal's method. The latter diol has b.pt. 135°—140° C. at 9 mm., and when dehydrated by oxalic acid and water yields an alcohol, $C_{10}H_{17}OH$, b.pt. 219°—221° C., sp. gr. 0.9250 at 22° C., $n_D = 1.4790$, which is probably Δ^3 -menthene-2-ol containing a little Δ^1 (3)-menthene-2-ol. (See also J. Chem. Soc., Oct., 1918.)—C. S.

Terpenes and essential oils. CXXI. *Pulegenic acid and the conversion of carvone into pulegenic acid.* O. Wallach and W. von Rechenberg. *Annalen*, 1917, **414**, 233—243.

AN improved method of preparing pulegenic acid from pulegone dibromide by the action of aqueous potassium hydroxide is described. The conversion of pulegenic acid into dihydropulegenic (1-methyl-3-isopropyl-cyclopentane-2-carboxylic) acid, which cannot be effected by direct reduction of the acid or of its amide, has been accomplished indirectly through methyl hydrochloropuleginate. The amide of the reduced acid is converted by Hofmann's method into a base, presumably 2-amino-1-methyl-3-isopropyl-cyclopentane. The conversion of the 6-ring in carvone into the 5-ring of pulegenic acid and the formation of this acid from dihydrocarvenolic acid have been effected. (See also J. Chem. Soc., 1918, i., 428.)—C. S.

Terpenes and essential oils. CXXII. *Behaviour of the nitrosochloride additive compounds towards reagents which eliminate hydrogen chloride.* O. Wallach, J. Wolff, and M. Walter. *Annalen*, 1918, **414**, 257—270.

AN excellent method for converting a nitrosochloride into an oxime is to heat it with a mixture of acetone and pyridine on the water-bath for 10—15 minutes; for example, limonenenitrosochloride is thus converted into carvoxime. In the case of certain nitrosochlorides hydrogen chloride is eliminated in the case of these by different reagents. Thus α -terpineolnitrosochloride is converted into 8-hydroxy- Δ^6 -menthene-2-oneoxime by the preceding method, but when heated with anhydrous sodium

acetate and glacial acetic acid it yields a crystalline substance, $C_{10}H_{17}O_2N$, m.pt. 139° C., which is regarded as an oxime-oxide. β -Terpineolnitrosochloride does not yield a well-characterised oxime. The crystalline substances obtained by the action of methyl or ethyl alcohol on the nitrosochloride and recrystallised from either of the two alcohols are probably mixtures. (See also J. Chem. Soc., 1918, i., 439.)—C. S.

Terpenes and essential oils. CXXIII. *Behaviour of dibrominated hexacyclic ketones in relation to the position of the bromine atoms.* O. Wallach, H. E. Woodman, W. Jessen, A. Hallstein, and E. Grote. *Annalen*, 1918, **414**, 271—296.

WHEN dibromo derivatives of menthone and of carvomenthone are shaken for 2—3 days at the ordinary temperature with 2% aqueous potassium hydroxide, the products may be monobromides, phenols, aliphatic ketonic acids, or pentacyclic hydroxy-carboxylic acids according to the positions of the bromine atoms. Rules are formulated correlating these positions and the nature of the product. For example, 1,2-dibromomenthone is converted into *m*-cresol, and 1,6-dibromocarvomenthone into ϵ -keto- β -isopropylheptonic acid. (See also J. Chem. Soc., 1918, i., 440.)—C. S.

Terpenes and essential oils. CXXIV. *Method of transforming hexacyclic ketones into cyclopentanones based on the conversion of dibrominated cyclohexanones into pentacyclic α -hydroxy-carboxylic acids.* O. Wallach, M. Gerhardt, and W. Jessen. *Annalen*, 1918, **414**, 296—366.

THE dibrominated cyclohexanones which are converted into hydroxycyclopentanecarboxylic acids by aqueous alkali hydroxide (see preceding abstract) are in general easily obtained by treating the cyclohexanone in glacial acetic acid solution with four atoms of bromine. The first products of the interaction with the alkali to be isolated are substances which have the composition of α -diketones but behave like unsaturated ketols. The hydroxycyclopentanecarboxylic acids yield cyclopentanones by oxidation with lead peroxide and sulphuric acid. (See also J. Chem. Soc., 1918, i., 442.)—C. S.

Terpenes and essential oils. CXXV. *Compounds of the eucarrone series.* O. Wallach and M. Standacher. *Annalen*, 1918, **414**, 367—375.

By reduction with sodium and alcohol β -dihydrocarboxime yields tetrahydrocarvylamine, $C_{10}H_{19}N$, b.pt. 208.5° C., sp. gr. 0.8680 at 21° C., $n_D = 1.4665$, several derivatives of which are described. By bromination in glacial acetic acid tetrahydroeucarrone yields, at 0° C., a monobromoderivative, $C_{10}H_{17}OBr$, m.pt. 32° C., or, without cooling, a dibromo-derivative, $C_{10}H_{16}OBr_2$, m.pt. 68° C. When treated with aqueous potassium hydroxide the former is converted into hydroxy-tetrahydroeucarrone, $HO.C_{10}H_{17}O$, b.pt. 98° C. at 12.5 mm., sp. gr. 0.9810 at 20° C., $n_D = 1.4626$, and the latter into a saturated acid, $C_{10}H_{18}O_2$, m.pt. 91.5°—92.5° C., the constitution of which has not yet been determined. (See also J. Chem. Soc., 1918, i., 444.)—C. S.

Elemicin and isoclemicin; Synthesis of —. F. Mauthner. *Annalen*, 1917, **414**, 250—255.

2,6-DIMETHOXYPHENYL allyl ether, $C_9H_9(OCH_3)_2O.CH_2CH:CH_2$, a colourless oil, b.pt. 140°—141° C. at 14 mm., prepared from allyl bromide and pyrogallol 2,6-dimethyl ether in boiling acetone in the presence of powdered potassium carbonate, is con-

verted at 220° C. into 2,6-dimethoxy-4-allylphenol, $\text{HO.C}_6\text{H}_2(\text{OCH}_3)_2\text{CH}_2\text{CH}:\text{CH}_2$, b.pt. 168°–169° C. at 11 mm., the methylation of which yields 3,4,5-trimethoxyallylbenzene, identical with elemicin. The position of the allyl group is proved by oxidising the substance to gallic acid trimethyl ether, and of the double linking by decomposing the ozonide with water, whereby homogallaldehyde trimethyl ether is produced. Synthetic elemicin is converted into isoelemicin (3,4,5-trimethoxypropenylbenzene) by warming with alcoholic potassium hydroxide; the ozonide of the latter yields gallaldehyde trimethyl ether on treatment with water.—C. S.

Ginger; Pungent principles of —. II. H. Nomura. Sci. Rep. Tohoku Imp. Univ., 1918, 7, 67–77.

THE pungent principles of Japanese ginger on distillation yield, in addition to zingerone (this J., 1917, 1062), a substance, shogaol, $\text{C}_{15}\text{H}_{20}\text{O}_5$, b.pt. 231°–238° C. at 15.5 mm., and sp. gr. 1.0448 at 25° C., $n_D^{25}=1.52467$; this contains a methoxyl radicle and also a hydroxyl group, the presence of the latter being demonstrated by the conversion of shogaol into monomethyl, monoethyl and monoacetyl derivatives. The presence of a ketonic group is also probable and reduction with hydrogen and platinum black yields a dihydro-derivative, thus proving shogaol to contain one double bond. (See also J. Chem. Soc., 1918, i., 446.)—D. F. T.

Phenolic ketones; Synthesis of some — and their tastes. H. Nomura and F. Nozawa. Sci. Rep. Tohoku Imp. Univ., 1918, 7, 79–92.

IN order to decide on what constitutional factors the pungent taste of zingerone (4-hydroxy-3-methoxyphenylethyl methyl ketone) depends, an examination has been made of a number of phenylethyl methyl ketones containing hydroxyl or methoxyl groups substituted into the aromatic nucleus and also of 4-hydroxy-3-methoxyphenylethyl phenyl ketone. The results indicate that of the substances thus tested, those having a free hydroxyl group in the para position to the ketonic side chain, especially those derived from vanillin, have a pungent taste similar to zingerone. The degree of pungency is considerably influenced by the position of the hydroxyl group relative to the ketonic side chain, and is increased by the presence of a meta-methoxyl group. The influence of the simple hydrocarbon radicle attached to the ketonic group is little greater than that of the position of the hydroxyl radicle because 4-hydroxy-3-methoxyphenylethyl phenyl ketone resembles zingerone in taste. (See also J. Chem. Soc., 1918, i. 438.)

—D. F. T.

Cephalin. V. Hydrocephalin of the egg-yolk. P. A. Levene and C. J. West. J. Biol. Chem., 1918, 35, 285–290.

HYDROCEPHALIN has been isolated in an almost pure state from the preparation of hydrolecithin in which it was detected as an impurity (see this J., 1918, 136A). (See further J. Chem. Soc., 1918, i., 421.)—H. W. B.

Histidine and carnosine. Synthesis of carnosine. L. Baumann and T. Ingvaldsen. J. Biol. Chem., 1918, 35, 263–276.

CARNOSINE is shown to be β -alaninehistidine by synthesis from histidine and β -iodopropionyl chloride as well as by deamination, followed by hydrolysis, when a 70% yield of histidine is obtained. The isomeric histidyl- β -alanine could

not be prepared. Carnosine is not hydrolysed by extracts of dog's liver or muscle. (See further J. Chem. Soc., 1918, i., 454.)—H. W. B.

Foaming; Inhibition of — [by isoamyl isovalerate]. C. H. Fiske. J. Biol. Chem., 1918, 35, 411–413.

ISOAMYL isovalerate is recommended as a foam inhibitor in analytical operations, and two methods are described for its preparation: (1) by heating a mixture of isoamyl alcohol and isovaleric acid in the presence of concentrated sulphuric acid, and (2) by oxidising isoamyl alcohol with potassium bichromate and sulphuric acid. (See further J. Chem. Soc., Oct., 1918.)—H. W. B.

Aldehydes; Reduction of — to corresponding alcohols. I. Reduction of heptioic aldehyde (ananthol). P. A. Levene and F. A. Taylor. J. Biol. Chem., 1918, 35, 281–283.

THE reduction is effected by an emulsion of metallic sodium in toluene. The calculated quantity of sodium is suspended in dry toluene, heat applied until the sodium melts, the liquid stirred vigorously in order to form a fine emulsion, and then cooled quickly in ice, the stirring being continued. The aldehyde, dissolved in glacial acetic acid and toluene, is then added slowly, and when the reduction is finished, water is added to dissolve the sodium acetate, and the toluene layer separated and fractionally distilled. The yield of heptioic alcohol from ananthol was 58% of that theoretically obtainable.—H. W. B.

PATENTS.

Ethylidene diacetate; Manufacture of —. Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet, et Cartier, Paris. Eng. Pat. 112,766, Oct. 29, 1917. (Appl. No. 15,756 of 1917.) Under Int. Conv., Dec. 9, 1916.

ACETYLENE is converted into ethylidene diacetate by passing the gas into a solution of 40 parts of mercuric oxide and 20 parts of methylene sulphate in 1100 parts of glacial acetic acid at 50°–70° C., the current of gas being so regulated that absorption is complete and being continued until 200 parts have been fixed. Other alkyl sulphates may be used in place of methylene sulphate.—D. F. T.

Alkylating reagents; Preparation of certain —. J. C. Irvine and W. N. Haworth, St. Andrews. Eng. Pat. 117,824. (Appl. Nos. 5537, Apr. 20, and 12,885, Sep. 8, 1917.)

By the action of sulphuryl chloride on methyl or ethyl alcohol a mixture of the corresponding dialkyl sulphate and alkyl hydrogen sulphate is obtained. The reactions may be represented $2\text{R.OH} + \text{SO}_2\text{Cl}_2 = \text{H.O.SO}_2\text{OR} + \text{RCl} + \text{HCl} + 2\text{R.OH} + \text{SO}_2\text{Cl}_2 = \text{SO}_2(\text{OR})_2 + 2\text{HCl}$. The sulphuryl chloride may be prepared separately and used in the crude or rectified condition, small quantities being added to the alcohol as long as the desired reaction occurs, but care is necessary to avoid exceeding 5% above the semimolecular proportion of the chloride. It is advantageous to retain in the reaction system the alkyl chloride produced, because this tends, by mass action, to reduce the formation of alkyl hydrogen sulphate. Instead of using pre-formed sulphuryl chloride, equimolecular quantities of chlorine and sulphur dioxide may be passed into the alcohol, or the gases may be introduced alternately, care then being taken to avoid the chlorine being present in an excess of the molecular proportion of the sulphur dioxide. On distillation of the final reaction product under reduced pressure the

alkyl hydrogen sulphate undergoes decomposition into sulphuric acid and dialkyl sulphate, so that the latter is obtained in good yield.—D. F. T.

Photochemical [chlorinating] apparatus. W. O. Snelling, Pittsburgh, Pa. U.S. Pat. 1,271,790, July 9, 1918. Date of appl., July 1, 1914. Renewed Jan. 3, 1918.

THE apparatus consists of a reaction chamber, the side walls of which are impervious to light, carrying a series of parallel plates pervious to light which are so arranged as to afford a continuous passageway for gases (chlorine and substances to be chlorinated) around the plates from the inlet at one end of the chamber to the outlet at the other. The arrangement is such that light, directed on the apparatus, will act with greatest actinic effect on the gases nearer the outlet and with less actinic effect on the gases nearer the inlet, there being a means for regulating the temperature of the reacting gases passing through the passageway.—W. G.

Protoid silver; Preparation of —. Y. Nukada, Tokyo, Japan. U.S. Pat. 1,272,987, July 16, 1918. Date of appl., Sep. 21, 1917.

THIRTY pounds of "natto" is added to 12 gallons of water and the whole heated for six hours at 100° C., the liquid then being filtered and evaporated on a water bath to a volume of 9 cub. m. After standing 12 hours the solution is filtered and to it is added 175 grms. of silver nitrate.—W. G.

Caffeine; Process of recovering —. L. Fontanelli, Ferrara, Italy. U.S. Pat. 1,273,054, July 16, 1918. Date of appl., Aug. 27, 1917.

SOOT produced in the roasting of coffee is heated in a restricted current of gas to vaporise the caffeine, and the gas is then cooled to condense the caffeine.—W. F. F.

Mercury compound; Preparation of an organic —. R. Lüders, Berlin-Steglitz. Ger. Pat. 306,198, May 5, 1916.

α -AMINO BUTYRIC acid in slightly alkaline solution is treated with mercuric oxide. The resulting compound is easily soluble in water and shows a faintly acid reaction; part of the combined mercury is not precipitable by the usual reagents.—J. F. B.

Mercury preparations for therapeutic purposes; Process of producing —. H. Buchtala, Gratz, Austria, Assignor to Dr. Bayer es Tarsa, Budapest. U.S. Pat. 1,271,846, July 9, 1918. Date of appl., Aug. 18, 1915.

SEE Ger. Pats. 267,411 and 267,412, and Eng. Pat. 11,302 of 1913; this J., 1914, 229, 767.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Ammonium persulphate; Effect of the iron content of — on its photographic reducing power. S. E. Sheppard. Communication No. 60 from Eastman Kodak Research Lab. Brit. J. Phot., 1918, 65, 314—315.

THE reaction between silver and ammonium persulphate is very slow, the reactions between silver sulphate and ammonium persulphate and between silver persulphate and metallic silver being much more rapid. The reducing action of a pure persulphate bath is therefore very slow in starting,

but the solution can be activated by the addition of small quantities of silver solvents such as silver sulphate or ferric sulphate. The variation in the initial activities of different samples of persulphate is due to the variable iron content; if this rises above 1 to 2 parts of iron per 1000 of persulphate, the resulting solution is too active to be under proper control. The fact that the reaction product (silver sulphate) increases the activity of the persulphate solution explains the greater proportional effect of the reducer on high densities.—B. V. S.

PATENTS.

Coloured photographic image and method of producing the same. Ives-Lives Corporation, Assignees of F. E. Ives, Philadelphia, Pa. Eng. Pat. 113,617, Feb. 19, 1918. (Appl. No. 2910 of 1918.) Under Int. Conv., Feb. 20, 1917.

A RED image is obtained by copper-toning a black silver image in, for instance, a copper-ferricyanide-citrate toning bath, removing the silver salt, which is formed in the toning, by treatment with thio-sulphate, and then treating with a solution of a dye or dyes, e.g., Fuchsin and Auramine, to which copper acts as a mordant.—B. V. S.

Natural colour cinematography. L. F. Douglass, San Rafael, Cal., U.S.A. Eng. Pat. 117,864, Oct. 19, 1917. (Appl. No. 15,226 of 1917.)

ALTERNATING screens of two complementary colours, e.g., red and blue-green, are used in taking the negative, from which a black and white positive is taken in the usual way. The positive is then stained or toned in suitable baths in two processes, one of the alternating sets of pictures being masked, e.g., by coating with a spirit-soluble varnish, while the other set is being treated.—B. V. S.

Colour photography. F. E. Ives, Philadelphia, Pa. U.S. Pat. 1,268,847, June 11, 1918. Date of appl., Jan. 15, 1917.

A TWO-COLOUR mosaic taking-screen is employed, the two components being respectively complementary to two of the primary colours. This is provided with a sensitive film sensitised to these two primary colours, which in turn is placed in contact with a second film sensitive to the third primary colour and stained to prevent action of the first two primary colours. Exposure is made through the mosaic screen. In printing from the two negatives thus obtained, two positives are made from the one negative and one from the other and the three positives are combined.—B. V. S.

Photographs; Method of and article for making —. J. G. Capstaff, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,273,457, July 23, 1918. Date of appl., Jan. 6, 1917.

A SENSITISED gelatin film is applied to a transparent support first provided with a separating opaque silver screen obtained by a preliminary sensitive coating which has been exposed, developed, etc., in the usual way before applying the second film. The support may be provided with a sensitised coating on the other side also, the opaque screen then acting as a protection to each film during exposure of the other. After exposure through a colour-sensation record and development, etc., the film is treated with a bleaching-hardening bath and a suitable dye bath. The back film is bleached and hardened along with the exposed parts of the upper film, so that only the unexposed parts of the latter are stained.—B. V. S.

Tellurium toning-bath and process of toning photographic elements. E. R. Bullock, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,273,797, July 23, 1918. Date of appl., Apr. 5, 1916.

A SEPIA tone is produced on a silver image by treatment in a bath containing tellurium chloride, hydrochloric acid, sodium chloride, and potassium bromide. The resulting image may be intensified and the tone modified by further treatment in an aqueous solution of sodium sulphide.—B. V. S.

Treatment of textile fabrics, wood, leather, and other materials. Eng. Pat. 117,640. See V.

XXII.—EXPLOSIVES; MATCHES.

Smokeless powder; Detection of acidity in —. A. Angeli. Atti R. Accad. Lincei, 1918, 27, I., 164—166.

ALL the known methods of determining the stability of smokeless powder exhibit disadvantages and the author proposes to replace them by the use of the indicator, dimethylaminoazobenzene. The latter forms red salts, which become fixed to the surface of the explosive like a dyestuff to a fibre. A few c.c. of distilled water containing three or four drops of a 0.2% alcoholic solution of the indicator is poured on to about 0.5 gm. of the powder, the whole being well stirred. Powder of good quality turns lemon-yellow, whereas if more or less acidity is present, it becomes more or less intensely red; in either case, the supernatant liquid remains completely colourless. Not all explosives which are acid show low stability when subjected to the heat test, but experiment demonstrates that they inflame far more readily than normal explosives when kept in large amount at a relatively high temperature, and they also burn irregularly and incompletely, and in the firing test exhibit abnormalities in the pressure and range. A dilute solution of the above indicator may be used for revealing the effect of light on smokeless powder; the parts of the latter which have been exposed are turned red by the solution, whereas the other parts become yellow.—T. H. P.

Source of error in Bunsen's method for determination of chlorates, peroxides, etc. Rapp. See VII.

PATENTS.

Nitro-compounds [trinitrotoluene]; Method of separating — from liquids. F. M. G. Johnson, Montreal, Canada. U.S. Pat. 1,271,578, July 9, 1918. Date of appl., Sep. 18, 1917.

SPENT acid containing trinitrotoluene is confined at pressures below atmospheric until the solid particles are floated to the surface by adhering gas bubbles. The cleared acid is drawn off from below the floating mass, and the latter is then heated sufficiently to melt the trinitrotoluene.—T. St.

Method of producing ammonium perchlorate. U.S. Pat. 1,273,477. See VII.

XXIII.—ANALYSIS.

Analytical results; Calculation of —. J. Grossfeld. Chem.-Zeit., 1918, 42, 389—391.

Factors are given in tabular form for calculating results from analytical data. The tables include factors for many elements, inorganic and organic compounds and acids, sugars, alkaloids, etc. (See also J. Chem. Soc., Oct., 1918.)—W. P. S.

Colorimeter; New form of —. J. C. Bock and S. R. Benedict. J. Biol. Chem., 1918, 35, 227—230.

In the new instrument, the prisms employed in the Duboscq colorimeter are replaced by mirrors, and there is only one plunger, a cell of known dimensions being substituted for the other. (See also J. Chem. Soc., Oct., 1918.)—H. W. B.

Gases; Apparatus for measurement of — in volumetric analysis. H. Fincke. Chem.-Zeit., 1918, 42, 415.

A 200—250 c.c. graduated cylinder is closed by a rubber stopper carrying a siphon with arms of equal length, one of which reaches nearly to the bottom of the cylinder and the other nearly to the bottom of a taller and wider cylinder, and a tube bent at an angle of 45° and connected to a reaction flask containing a weighed quantity of the sample sufficient to yield about 100—150 c.c. of gas. The acid or other reagent is contained in a flask which is connected to the reaction flask by means of a tube bent at right angles. The graduated cylinder and the siphon are filled with a saturated solution of common salt. The flask containing the reagent is inverted and the latter then flows into the reaction flask, the gas evolved expelling a corresponding volume of salt solution from the first into the second graduated cylinder. In this apparatus the use of india-rubber tubing and stopcocks is avoided. (See also J. Chem. Soc., Oct., 1918.)—A. B. S.

Gas analysis; Use of the interferometer in —. F. M. Seibert and W. C. Harpster. U.S. Bureau of Mines, Tech. Paper 185, 1918. 18 pages.

In special work requiring analysis of gases at frequent intervals, the Rayleigh interferometer, as adapted to gas analysis by Haber and Lowe (this J., 1906, 802), has partly supplanted the older analytical methods. It is suitable for analysing binary gas mixtures such as occur in mines, in the production of oxygen from liquid air, and in the commercial production of hydrogen. For accurate determinations the gas chambers consist of a cylindrical metal tube 1 metre long, and divided lengthwise by a metal partition, the upper half containing the gas to be tested, while the lower section is filled with a gas used for comparison. Parallel rays from a Nernst lamp pass through the object glass of a collimator and travel in three parts to an observation telescope, producing an image of the slit with diffraction bands. The lower half of the pencil of rays is divided into two parts by the metallic partition between the gas chambers, each part also passing through a compensator plate, the upper part of which is fixed and the lower part capable of movement by means of a micrometer screw. Thus the optical path of the gas in the lower section of the gas chamber can be varied. When both chambers are filled with the same gas, the interference effect produced by the lower half of the pencil of rays is similar to that produced by the upper half, but if a difference in the gas composition in the two sections exists, the lower band image is moved laterally and can be brought back to a zero position by manipulation of the compensating plate. The measure of the movement of the compensator is a measure of the refractive difference between the two gases, which must be dry and at the same temperature. In mine gases a decrease in the amount of oxygen and a corresponding increase in the amount of nitrogen as compared with atmospheric air would show imperfect ventilation. Among other technical uses the instrument may be used to detect contamination of hydrogen with

heavy gases, and the degree of carburisation of illuminating gas carburetted with benzene. (See also J. Chem. Soc., Oct., 1918.)—C. A. K.

Volatile substances; Manipulation of —. III.
A. Stock. Ber., 1918, 51, 983–989.

THE following pieces of apparatus are fully described. I. An improved form of gas holder for substances which can be condensed by liquid air (see Ber., 1917, 50, 1006). II. (a) An arrangement for filling a tube with a gas or mixture, and sealing it, without exposure to the air, and (b) a "vacuum tube opener" for breaking the capillary of a sealed tube and leading off the gases without exposure to the air. III. A simple apparatus for analysing a gaseous mixture by measuring the pressure of the gas left uncondensed at different temperatures. (See further, J. Chem. Soc., Oct., 1918.)—J. C. W.

[Acidity:] *A new physico-chemical volumetric method [for determining —].* R. Dubrisay. Ann. Chim., 1918, 9, 25–18.

THE method is based on a determination of the number of drops formed when a definite volume of vaseline oil mixed with stearic acid is allowed to flow slowly into a given volume of the liquid, of which it is required to determine the acidity, before and after the addition of increasing amounts of standard alkali. It is found that there is a sharp rise in the number of drops formed when the liquid is just neutralised.—W. G.

Tungsten and vanadium; Determination of — in the presence of titanium. G. Fenner. Chem.-Zeit., 1918, 42, 403.

WHEN a mineral, etc., containing tungsten and titanium is fused with sodium peroxide, the melt then treated with water, boiled for a few mins., and filtered, the titanium remains insoluble in the iron precipitate whilst the tungsten is completely soluble and is found in the filtrate. Vanadium, if present in small quantity (less than 0.5%), remains almost entirely insoluble, but in larger quantity a portion is found in the filtrate. To determine vanadium in the presence of titanium, the mineral is treated with hydrofluoric acid and sulphuric acid to remove silica, the residue is then fused with sodium pyrosulphate, the melt dissolved in dilute sulphuric acid, the solution filtered, and the filtrate treated with hydrogen peroxide until a distinct yellow coloration has developed, a large excess of peroxide being avoided. Ammonium fluoride or hydrofluoric acid is then added, whereby the yellow colour of the titanium compound is destroyed, whilst the red-brown coloration of the vanadium compound remains unaffected. Phosphoric acid is added to remove colour due to iron salts, and the vanadium is determined colorimetrically by comparison with a standard prepared with the same quantities of reagents. (See also J. Chem. Soc., Oct., 1918.)—W. P. S.

Mercury; A new method of estimating — by means of zinc filings. M. François. Ann. Chim., 1918, 10, 84–100.

A MORE detailed account of work already published (see this J., 1918, 445A).—W. G.

Quick determination of incombustible matter in coal and rock dust mixtures in mines. Fieldner and others. See IIa.

PATENTS.

Vapours in gases; Process for the quantitative estimation of —. H. Simmonds and M. D. Davis, Winnipeg, Canada. U.S. Pat. 1,272,922, July 16, 1918. Date of appl., Oct. 15, 1917.

THE process consists in filling to the same pressure two flasks connected by a manometer, the one with the gas to be analysed and the other with an inert

gas free from the vapour in question, and breaking inside each flask a sealed glass bulb, containing a liquid of the same composition as the vapour to be estimated in quantity larger than that required to saturate with the vapour, at that temperature, the gas in the flask in which it is broken. The original concentration of the vapour in the gas is calculated from the differential pressure which develops between the two flasks.—W. G.

Impact testing machines. W. & T. Avery, Ltd., and E. A. Allcut, Birmingham. Eng. Pat. 118,175, Sep. 22, 1917. (Appl. No. 13,635 of 1917.)

Testing gases: Method and apparatus for —. F. Haber and R. Leiser, Berlin-Dahlem, Germany. U.S. Pat. 1,269,599, June 18, 1918. Date of appl., Apr. 30, 1914.

SEE Eng. Pat. 9344 of 1914; this J., 1915, 926.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Bigot. Tunnel furnaces. 15,255. Sep. 19. (Fr., Nov. 8, 1917.)

Gal. Furnaces. 15,265. Sep. 19. (Fr., Jan. 12.)

Garbutt. Rotary furnaces. 15,683. Sep. 26.

Gloss. Drying-plant. 15,631. Sep. 16. (Fr., Apr. 17, 1917.)

Imperial Trust for Encouragement of Scientific and Industrial Research, and Truscott. Apparatus for separating materials of varying specific gravities. 15,397. Sep. 21.

Kestner. Apparatus for enabling extracts, infusions, or decoctions to be obtained in a continuous manner. 15,397. Sep. 21.

Mead. Heating-furnaces. 15,074. Sep. 17.

Sarron and Simon. Producing changes of physical state or endothermic chemical reactions. 15,542. Sep. 24.

Smallwood. Apparatus for cooling liquids or subjecting them to the action of air or gas. 15,281. Sep. 20.

Soc. l'Air Liquide. Apparatus for effecting exothermic chemical syntheses. 15,514. Sep. 24. (Fr., Feb. 20.)

Walsh. Obtaining hot air for heating or drying. 15,140. Sep. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

3866 (1917). Bontemps and Vis. Apparatus for the continuous separation of solids from liquids. (118,855.) Sep. 25.

13,021 and 13,022 (1917). Nicholas. Separation of liquids from solids. (110,349 and 110,350.) Sep. 25.

14,217 (1917). Urquhart. Evaporating and distilling machinery. (119,106.) Oct. 2.

14,251 (1917). Bowler and others. See XIX.

18,093 (1917). Clarke. Drying apparatus. (119,156.) Oct. 2.

18,459 (1917). Candlot. Ball mill. (115,223.) Sep. 25.

6614 (1918). Alexander. Apparatus or kilns for drying granular, pulverulent, or pasty materials. (119,198.) Oct. 2.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING

APPLICATIONS.

Alchevsky. Artificial fuel. 15,774. Sep. 27.

Beilby. Carbonisation of coal, shale, peat, etc. 15,599. Sep. 25.

Benton. Treatment of shales, cannel coal, and organic refuse to recover oils, fats, ammonia, etc. 15,276. Sep. 20.

Bost. Wood distillation. 15,432. Sep. 23.

Bourne. Producing working mixture for internal-combustion engines. 15,134. Sep. 17.

Brown, and Simon-Carves, Ltd. Gas washer. 15,208. Sep. 19.

Colman and Harman. Manufacture of coal gas. 15,448. Sep. 23.

Gray. Gas producers. 15,041. Sep. 16.

Jackson (Naaml. Vennootsch. Nederlandsche Lichte Olie Maatsch.). Converting higher molecular carbo-hydrates into lower ones. 15,057. Sep. 16.

Knowles. Composition for treating coal, etc., for manufacture of water-gas. 15,635. Sep. 26.

Leamon. Treatment of gases containing hydrogen sulphide. 15,568. Sep. 25. (U.S., Nov. 8, 1917.)

Oswald. Retorts. 15,039. Sep. 16.

Porat. Production of paraffin, waxes, oils, or fats from peat, peat straw, mosses, lichens, algae, grass, straw, etc. 15,357. Sep. 21.

Westinghouse Lamp Co. Treatment of filaments for incandescence lamps. 15,523. Sep. 24. (U.S., Oct. 15, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

8461 (1917). Lynn and Rambush. Ammonia-recovery producer-gas process and apparatus. (119,049.) Oct. 2.

12,802 (1917). Payne. See III.

12,809 (1917). Axtell. Liquid fuels. (109,806.) Oct. 2.

13,714 (1917). Edgeworth. Treatment of peat for fuel. (118,903.) Sep. 25.

18,478 (1917). Blair, Campbell, and McLean, Ross, and Corner. Mechanical retorts for destructive distillation of sawdust, shavings, small wood, peat, beans, nuts, etc. (118,960.) Sep. 25.

18,689 (1917). Sieurin. Transforming anthracite, coke, etc., into a product suitable for manufacture of carbon electrodes. (119,164.) Oct. 2.

4622 (1918). Bouillon. Treatment of peat. (118,993.) Sep. 25.

8258 (1918). Lynn and Rambush. Gas producers. (119,207.) Oct. 2.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Benton. 15,275. See XII. 15,276. See II.

Fryer, and Rowntree and Co. Combination of pitch, etc. 15,809. Sep. 28.

Jackson. 15,057. See II.

COMPLETE SPECIFICATIONS ACCEPTED.

12,802 (1917). Payne. Treatment of hydrocarbon oils. (119,066.) Oct. 2.

14,166 (1917). Koppers Co. See XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Broadhurst, Lamble, Peachey, and United Alkali Co. Manufacture of substitute for celluloid or leather, etc. 15,244. Sep. 19.

Farquharson. Apparatus for coating papers, fabrics, etc., with waterproofing or other materials. 15,169. Sep. 18.

Grant. Waterproofing vegetable fibres, etc. 15,296. Sep. 20.

Gray and White. Installation for bleaching paper pulp, etc. 15,221. Sep. 19.

Schauffelberger. Manufacture of cellulose, etc. 15,772. Sep. 27.

Short, Short, and Tully. Compositions for treating textile fabric to render it waterproof and gas-tight. 15,168. Sep. 18.

Zdanowich. Manufacture of cellulose acetates. 15,163. Sep. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

13,208 (1917). Dreyfus. Manufacture of non-inflammable celluloid. (118,891.) Sep. 25.

8750 (1918). Aktiebolaget Cellulosa. Production of soda cellulose. (116,288.) Sep. 25.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Fish, and Jackson and Bro. Open-bleach kiers, etc. 15,146. Sep. 18.

Royle Dyeing Co. Dyeing machine for tubular knitted fabrics, etc. 15,420. Sep. 23.

COMPLETE SPECIFICATION ACCEPTED.

1225 (1918). Bright and Bros., and Evans. Machines for boiling, bleaching, dyeing, sizing, or similarly treating yarns or fabrics. (119,173.) Oct. 2.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Auden. Extraction of potash from alkaline, etc., minerals and manufacture of residual products into cement, china, etc. 15,431. Sep. 23.

Bloeky, and Walker and Sons. Manufacture of chrome liquors and salts. 15,786. Sep. 28.

Calvert. Production of cyanide and cyanogen compounds. 15,757. Sep. 27.

Gregory. Recovery of tin compounds. 15,389. Sep. 21.

Lamb. 15,496. *See* XV.

Leamon. 15,568. *See* II.

Lindblad. Production of cyanides and nitrides. 15,113. Sep. 17. (Sweden, June 8, 1917.)

Lunden and Thorssell. Production of nitrates by bacteria. 15,667 and 15,669. Sep. 26.

Lunden and Thorssell. Production of nitrates from ammonia, ammonium compounds, and organic nitrogen compounds. 15,668. Sep. 26.

Lunden and Thorssell. Production of calcium nitrate. 15,670. Sep. 26.

Lunden and Thorssell. Oxidation of ammonia, ammonium compounds, or organic nitrogen compounds. 15,671. Sep. 26.

Norsk Hydro-Elektrisk Kvaestofaktieselskab. Manufacture of concentrated nitric acid. 15,241. Sep. 19. (Norway, Oct. 30, 1917.)

Pierce. Manufacture of strontium peroxide. 15,691. Sep. 26.

Ross. 15,367. *See* XX.

Soe, Gros et Bouchardy. 15,540. *See* XVI.

Soc. Ind. de Produits Chimiques. Transforming free or combined ammonia mixed with inert gases into ammonium sulphate or concentrated or pure ammonia gas. 15,756 and 15,764. Sep. 27. (Fr., May 27 and June 22.)

COMPLETE SPECIFICATIONS ACCEPTED.

8461 (1917). Lynn and Rambush. *See* II.

13,234 (1917). Mower and Williams. *See* XVI.

13,519 (1917). Kenyon and Williams. Stepped brick for the walls of acid plants, etc. (119,087.) Oct. 2.

16,636 (1917). Bingham. *See* X.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Auden. 15,431. *See* VII.

Bigot. 15,255. *See* I.

Hughes. Apparatus for annealing glass. 15,364. Sep. 21.

McLean. Bricks for furnaces, etc. 15,018. Sep. 16.

Webster. Kilns for burning clay products, glazed ware, and pottery. 15,590. Sep. 25.

COMPLETE SPECIFICATION ACCEPTED.

13,906 (1917). Mason and Couper. Manufacture of refractory bricks, blocks, tuyeres, etc., used in connection with furnaces for smelting metals, etc. (119,101.) Oct. 2.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Auden. 15,431. *See* VII.

Grant. Production of roofing materials. 15,297 and 15,464. Sep. 20 and 23.

Olson. Process of making waterproof cement. 15,712. Sep. 26.

O'Reilly. Composition for insulating blocks, roofing tiles, etc. 15,755. Sep. 27.

COMPLETE SPECIFICATION ACCEPTED.

17,783 (1917). Quick. Composition and manufacture of bricks, slabs, etc. (119,152.) Oct. 2.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Aarts and Aarts. Process for sulphatising ores, etc. 15,830. Sep. 28. (Holland, Oct. 10, 1917.)

Adam and Stevenson. Detuning of tuned iron. 15,323. Sep. 20.

Alpha Products Co. Making castings of rare earth metals. 15,122. Sep. 17. (U.S., Sep. 17, 1917.)

Angel. Treatment and reduction of refractory sulphide, etc., ores. 15,035. Sep. 16.

Armstrong. Metallurgy of iron and steel. 15,744. Sep. 27.

Arnold. High speed steel. 15,554. Sep. 25.

Barelay and MacKenzie. Treatment of metals. 15,285. Sep. 20.

Bibby and Boving. Electric blast furnaces. 15,345. Sep. 20.

Cammell, Laird, and Co., Carter, and Williams. Furnaces for melting metals, etc. 15,551. Sep. 25.

Ferguson. Apparatus for concentrating ores, etc. 15,598. Sep. 25.

Mate and Poulson. Production of malleable iron. 15,806. Sep. 28.

Ross. 15,367. *See* XX.

Shotton. Manufacture of iron for malleable iron castings. 15,720. Sep. 27.

Vautin. Recovery of metals from slags. 15,027. Sep. 16.

Williams. Alloy. 15,555. Sep. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

8563 (1917). Webster, Edser, and Wood. Concentration of tin and wolfram ores. (119,050.) Oct. 2.

13,547 (1917). Jackson (Potthoff). Electro-plating apparatus. (119,091.) Oct. 2.

13,906 (1917). Mason and Couper. *See* VIII.

14,132 (1917). Eustis. Treatment of iron ore. (112,615.) Sep. 25.

14,915 (1917). Bertoya. Manufacture of tungsten metal powder. (119,117.) Oct. 2.

16,636 (1917). Bingham. Mechanical furnaces for roasting blende, pyrites, etc. (118,940.) Sep. 25.
 17,095 (1917). British Thomson-Houston Co. (General Electric Co.). Alloys. (118,947.) Sep. 25.
 2823 (1918). Bamfield. Case-hardening. (118,983.) Sep. 25.
 7074 (1918). Shepherd, and Brazil, Straker, and Co. Electro-deposition of iron. (119,200.) Oct. 2.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Bibby and Boving. 15,345. *See* X.
 British Thomson-Houston Co. (General Electric Co.). Electric furnaces. 15,320. Sep. 20.
 Clark, and Hart Accumulator Co. Electric accumulators or secondary batteries. 15,277. Sep. 20.

 9285 (1918). Kilburn (Norske Aktieselskab for Elektrokemisk Industri). Manufacture of carbon electrodes. (119,018.) Sep. 25.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Benton. Distillation of fatty acids, recovered grease, coal tar, etc. 15,275. Sep. 20.
 Benton. 15,276. *See* II.
 Hannin. Creosote soap. 15,091. Sep. 17.
 Porat. 15,357. *See* II.

COMPLETE SPECIFICATION ACCEPTED.

8929 (1917). De Bruyn. *See* XIX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Duke. Pigments, and production of same. 15,533. Sep. 24.
 Hutchins. Manufacture of lampblack. 15,444. Sep. 23.
 Hutchison. Non-inflammable paint. 15,750. Sep. 27.

COMPLETE SPECIFICATION ACCEPTED.

14,166 (1917). Koppers Co. Manufacture of resins from benzol plant residues. (112,419.) Oct. 2.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Banbury. Machines for treating rubber. 15,084—15,087. (U.S., Nov. 18, 1916, and Mar. 24, 1917.)
 Peachey. Rubber composition. 15,362. Sep. 21.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Blockey, and Walker and Sons. 15,786. *See* VII.
 Broadhurst and others. 15,244. *See* V.
 Lamb. Detanning chrome leather for manufacture of glue, etc., and recovery of chrome compounds. 15,496. Sep. 24.
 Potter. Leather substitute for soles of boots, etc. 15,083. Sep. 17.
 Schlakmann. Dressing, fleshing, and unhairing skins. 15,702. Sep. 26.

COMPLETE SPECIFICATION ACCEPTED.

9144 (1918). Tada. Preparation of gelatin. (119,210.) Oct. 2.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Fitzgerald. Manufacture of nitrogenous manures, etc. 15,312. Sep. 20.
 Soc. Gros et Bouchardy. Production of cyanamide. 15,540. Sep. 24. (Fr., Nov. 3, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

13,334 (1917). Mower and Williams. Apparatus for use in the manufacture of superphosphate. (119,074.) Oct. 2.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Goodwin. 15,507. *See* XIX.
 Greville. 15,423. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Greville. Brewing, and manufacture of brewing sugar, etc. 15,423. Sep. 23.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Goodwin. Treatment of semolina. 15,507. Sep. 24.
 Linden. Treating sludge. 15,328. Sep. 20.
 Nielsen. Apparatus for concentrating milk, etc. 15,561. Sep. 25.
 Wollaston. Softening water. 15,210. Sep. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

8929 (1917). De Bruyn, Ltd., and De Bruyn. Means for imparting a definite flavour to edible oils and fats. (119,052.) Oct. 2.
 12,354 (1917). Senior. Whey extract for use as food. (118,874.) Sep. 25.
 14,251 (1917). Bowler, Paterson, and Levy. Drying food and other products. (118,911.) Sep. 25.
 6502 (1918). Spencer and Kemp. Dried eggs in powder form. (119,007.) Sep. 25.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATION.

Ross. Manufacture and use of tungsten and its compounds for detection, prevention, and treatment of disease in animals. 15,367. Sep. 26.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Christensen. Manufacture of photographic plates and pictures. 15,194. Sep. 18.

I.—GENERAL ; PLANT ; MACHINERY.

Solvents; Recovery of — from air-vapour mixtures. E. L. Knoedler and C. A. Dodge. J. Ind. Eng. Chem., 1918, 10, 593—595.

A PLANT is described for the recovery of mixed vapours of methyl alcohol, ethyl alcohol, acetone, and camphor which are evaporated in drying the colloid coating of gas mantles. The mantles are passed continuously through a heated drying chamber supplied with a current of air under slight pressure. The air-vapour mixture from the drying chamber is conducted to the recovery plant, which consists of a large surface condenser acting as a pre-cooler, a group of scrubbing towers, receivers cooled by brine coils, and a column still. The vapours, after passing through the pre-cooler, enter the "bell-and-seal" scrubbing towers where they bubble through water at 5° C.; the solvent vapours are thus absorbed and the cooled air is returned to the pre-cooler where it serves to cool vapours just entering the plant. The air may then be discharged into the atmosphere or used over again in the drying chamber. The water in the scrubbing towers is used repeatedly until it has absorbed about 12% of solvent vapours, and is then distilled. The camphor remains in the sections of the still where the temperature ranges between 95° and 75° C., and is removed periodically. About 80% of the vapours passing through the plant are recovered, and the estimated cost is 0.26 dollar per gall. of recovered solvent without making any allowance for the camphor.—W. P. S.

PATENTS.

Continuous-rectification apparatus; Cooling plates for —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 110,910, Oct. 25, 1917. (Appl. No. 15,525 of 1917.) Under Int. Conv., Oct. 31, 1916. Addition to Eng. Pat. 105,549.

IN the cooling plates described in Eng. Pat. 105,549 (this J., 1918, 197A), the perforated plates are made in the form of a ring provided on the periphery with some larger perforations which serve to facilitate the starting of the apparatus. —W. H. C.

Condenser; Annular —. S. Hayek, Charlottenburg. Ger. Pat. 304,602, Apr. 16, 1916.

THE condenser comprises two concentric cylinders mounted within a casing. The inner cylinder has horizontal corrugations, the ridges of which extend nearly to the enclosing cylinder. There are gaps in the ridges at diametrically opposite places, the gaps in one ridge being displaced 90° from those in adjacent ridges. Cooling water is supplied to the outer casing, and flows thence to the central space within the inner cylinder.

[Grinding] mills; Edge runners, pan and like —. J. E. Savage, and Brinjes and Goodwin, Ltd., London. Eng. Pat. 118,465, Sep. 3, 1917. (Appl. No. 12,620 of 1917.)

THE grinding pan is supported on and driven by a vertical shaft, and its periphery is turned outwards and downwards so as to dip into an annular water seal on the enclosing casing. Dust from the pan is thereby prevented from reaching the gearing in the bottom of the casing. The two rollers in the pan are overhung from pivots supported entirely outside the pan, and each pivot is connected by bracing to a fixed parallel pivot so that the rollers rest freely on the bottom of the pan and may oscillate about the fixed pivot. A sleeve is interposed between each roller and its

spindle projecting outwards from the pan, and a second sleeve projects oppositely into the annular space between the first sleeve and the spindle. The second sleeve is braced to the parallel fixed pivot. Washers are provided between the sleeves at both ends to exclude dust and take up wear. The inner end of the sleeve and spindle projecting through the roller are covered by a detachable cap. The apparatus is intended more especially for use in the manufacture of explosives.—W. F. F.

Grinders; Breaker-plate for —. M. F. Williams, Assignor to Williams Patent Crusher and Pulverizer Co., St. Louis, Mo. U.S. Pat. 1,274,126, July 30, 1918. Date of appl., Feb. 12, 1918.

IN a grinding machine having rotary hammers mounted above an arcuate cage or grating, a breaker-plate is placed between the end of the sloping bottom of the feed hopper and the adjacent end of the cage. The front of the plate has a smooth upper face forming a continuation of the bottom of the feed hopper, and flush therewith, and a lower corrugated face to grind the material in conjunction with the rotary hammers. An intermediate step between the smooth and corrugated faces serves as a fulcrum for preliminary breaking of the feed by the hammers, prior to secondary reduction on the lower face and final reduction in the cage.—J. H. P.

Ball mill. D. H. Fairchild, Denver, Colo. U.S. Pat. 1,275,181, Aug. 6, 1918. Date of appl., May 31, 1917.

A BALL or pebble mill is provided with gratings spaced inwardly from the outer heads of the mill and with a central feed opening at one end and a central discharge opening at each end. Means are provided between each grating and the corresponding head for elevating the pulverised material to the adjacent discharge opening.—A. B. S.

Agitating liquids, powders, granular substances, and the like; Device or apparatus for —. F. Moore, Birmingham. Eng. Pat. 118,567, Mar. 19, 1918. (Appl. No. 4800 of 1918.)

A SQUARE wooden framework is mounted transversely on a horizontal shaft and has its sides projecting outwards at each corner of the square to form four shelves. Receptacles containing the substance to be agitated are strapped on the shelves, and the shaft and framework are rotated by a hand-wheel.—W. F. F.

Filter. A. J. Moisant, Assignor to General Research Laboratories. U.S. Pat. 1,270,042, June 18, 1918. Date of appl., Oct. 27, 1916.

TWO long vertical filter bags, one inside the other, and each supported by a wire frame, are mounted within a casing, the lower ends of the bags being fastened to the upper end of an outlet pipe which extends downwards to and through the bottom of the casing. Enclosing the filter bags is a non-perforated cylinder, closed at the top and open at the bottom; the lower end of the cylinder is some distance above the bottom of the casing but below the top of the outlet pipe. Around this cylinder is a foraminous cylinder. The space between the filter bags may be filled with a suitable filtering medium. The liquid to be filtered is fed into the casing at the top, flows through the foraminous cylinder, which retains coarse particles, rises in the space between the outer filter bag and the enclosing cylinder, and flows through the filter bags to the outlet pipe.

Oxidising apparatus. M. J. Chaplin, Seattle, Wash., Assignor to R. A. Brown, New York. U.S. Pat. 1,272,009, July 9, 1918. Date of appl., Mar. 15, 1917.

An annular retort is formed by an outer cylindrical wall and an inner conical wall; the latter is connected at the top with a chimney and the space enclosed by it forms the furnace. Surrounding the lower part of the chimney is a rotary annular hopper provided with a horizontal foraminous partition. Adjustable blades extend into the hopper and feed the material through the partition to delivery spouts extending into the retort. Means are provided for removing slag from the conical wall and the floor of the retort and directing it towards a discharge opening.

Kiln. M. M. Minter, Assignor to P. J. Brown, Albany, Ga. U.S. Pat. 1,272,495, July 16, 1918. Date of appl., Apr. 10, 1918.

In a series of progressively operated kilns, each kiln is connected with a flue through which gaseous fuel is supplied and also with a common exit flue. The kilns are connected with each other by flues which are also connected between each pair of kilns with the gas supply flue.—W. H. C.

Fire-resistant composition and process of making same. J. A. Zibell, Tappan, N.Y. U.S. Pat. 1,273,307, July 23, 1918. Date of appl., Mar. 9, 1918.

"RIPENED" milk is made into an emulsion and mixed with hydrated lime, sodium chloride, and a suitable pigment.—W. H. C.

Heating and drying apparatus. J. B. Muse, Cameron, N.C. U.S. Pat. 1,273,396, July 23, 1918. Date of appl., May 18, 1917.

A FURNACE provided with a casing having double walls spaced apart is arranged at one end of a drying chamber. Heat-distributing tubes, which serve also as a brace for the top of the inner casing, extend longitudinally from the space between the walls of the casing into the drying chamber.—W. H. C.

Dry-kiln. C. A. Lohman, Seattle, Wash. U.S. Pat. 1,274,911, Aug. 6, 1918. Date of appl., July 18, 1917.

A DRYING kiln is arranged immediately over a heating chamber, with a communicating opening at one side of the dividing floor. A vertical flue at the other side communicates with the drying chamber and with the lower part of the heating chamber. The openings on both sides are provided with dampers, and a circulation is maintained through both chambers. Steam heating pipes are arranged horizontally in the heating chamber just above the flue opening. A perforated horizontal air-supply flue extends through the heating chamber, and a discharge flue is provided for the drying chamber.—W. F. F.

Dehydrator; Continuous suction — with a fixed or horizontally moving filter base. A. Gerlach, Nordhausen. Ger. Pat. 306,259, Nov. 18, 1916.

THE filter base proper is protected by a superposed framework which holds and supports a strong subsidiary layer of filtering material; the filter base is thereby relieved of the pressure and movement of the wet material as this is moved along by an archimedean screw, and the ease with which the subsidiary filter-frame can be removed facilitates repairs or cleaning.—D. F. T.

Steam plate dryers. O. Kraushaar, Meuselwitz. Ger. Pat. 306,505, May 23, 1917.

By leading away the condensed water from one or more plates through a water trap and connecting the condensed water pipe with an air separator so that the air may be released intermittently or continuously, together with any occasional excess of steam, it is possible to obtain a considerable increase in the velocity of the flow of the steam and therefore also of the heat transference.

—D. F. T.

Drying apparatus. Kraftwerk Stettin Ges.m.b.H., Stettin. Ger. Pat. 306,515, Aug. 30, 1916.

Drying is effected by means of a closed steam coil or the like into which the vapours evolved from the material being dried are introduced by means of a steam jet pump. The drying chamber is closed, so that admixture of air with the vapours withdrawn therefrom is avoided.

Heating device for rotary drying cylinders, heated internally and externally. C. Runge, Willershausen. Ger. Pat. 306,748, Jan. 26, 1916.

THE drying cylinder is provided with wooden diaphragms at intervals along its length, and the heating chamber around it is subdivided by transverse walls, each section being connected by an adjustable inlet with the duct which supplies the drying medium throughout the length of the cylinder. By adjusting the heating valve of each section, the apparatus may be used for drying a variety of fruits.—D. F. T.

Centrifugal drying machine. T. A. Bryson, Troy, N.Y., Assignor to Tolhurst Machine Works. U.S. Pat. 1,273,817, July 30, 1918. Date of appl., Nov. 28, 1914.

THE machine consists of a rotating bowl with an outer cylindrical wall for holding a relatively dense and impervious layer separated by the centrifugal action. At intervals around the wall enclosed recesses are formed by perforated walls projecting from the cylindrical wall through the impervious layer. Liquid from within this layer passes through the perforations into the recesses.

—J. H. P.

Centrifugal machine. W. H. Uhland Ges.m.b.H., Leipzig-Gohlis. Ger. Pat. 306,670, Jan. 30, 1916.

THE machine comprises two concentric cones, of different taper, mounted on a common horizontal axis, the inner one rotating at a greater velocity than the outer. The separated solid is driven by centrifugal force into an annular chamber at the larger end of the cones. In this chamber is a screw which forces the separated material inwards to discharge openings in the end wall.

Separating entrained liquids from gases; Apparatus for —. J. P. Fisher, Bartlesville, Okla. U.S. Pat. 1,273,595, July 23, 1918. Date of appl., June 8, 1916.

THE gas is diverted through a by-pass main in which is an open tray having the shape of the pipe and provided with vanes which cause the gas to take a spiral path. An opening is left below the vanes for the passage of any liquid which separates.—W. H. C.

Refrigerating machine; Rotary —. C. Orr, Fort Wayne, Ind., Assignor to General Electric Co. U.S. Pat. 1,273,653, July 23, 1918. Date of appl., Sep. 15, 1916.

A CLOSED condenser within which is a reservoir for the refrigerating liquid is connected with a closed evaporator by a hollow shaft. The refrigerating

liquid flows from the reservoir to the evaporator through a pipe passing through the hollow shaft, and the flow is automatically stopped when the pressure in the condenser reaches a certain limit. The vapour from the evaporator passes through an oil separator into the hollow shaft and thence to the condenser. The separator is supported on the outlet pipe within the evaporator and is provided with a spout from which the separated oil can flow out only when the separator is tilted from its normal position.—W. H. C.

[Ammonia] condenser [for refrigerating apparatus]. L. Block, Mamaronock, N.Y. U.S. Pat. 1,271,268, July 2, 1918. Date of appl. May 20, 1915.

COMPRESSED ammonia gas passes through a pipe, provided with an injector nozzle, to the lowest turn of a coil over which water flows downwards. The gas passes upwards through the coil and is liquefied, the liquid ammonia leaving through a pipe at the top. A branch pipe leads from the outlet pipe to the injector nozzle on the gas inlet pipe, so that part of the liquefied ammonia is drawn into the coil with the entering gas, whereby the efficiency of the condenser is increased.

Solid constituents from an emulsion; Electro-osmotic process of separating —. A. Gerlach, Nordhausen. Ger. Pat. 305,217, Oct. 1, 1916.

Solid constituents are separated from an emulsion, and subsequently dried by a process of electro-osmosis, effected by means of a roller-shaped anode rotating between surrounding cathodes, which are constructed in sections to which the current is separately conducted. One of these sections, connected with a feed hopper, approaches nearer to the anode in the direction of rotation of the latter, and those sections which effect the subsequent dehydration are pressed by means of springs against the layer of partly dehydrated material on the anode.—C. A. M.

Feed pipe for hot gases for rotary drums and vessels. R. Bergmans, Berlin-Wilmersdorf. Ger. Pat. 306,506, July 31, 1917.

The conical nozzle of the pipe supplying the heated gas fits into an opening in the end of the rotating drum or vessel and contains a concentric cone, by the adjustment of which the flow of gas can be regulated. The cone is hollow and is perforated near its apex; its interior is connected through the hollow supporting rod and a piece of flexible tubing with one arm of a glass U-tube, the other arm of which is connected with the space outside the nozzle; the position of the cone is then adjusted so that a liquid in the U-tube stands at approximately the same level in each limb.—D. F. T.

Fires; [Apparatus for] extinguishing of —. C. H. Meigs and F. A. Epps, New York. Eng. Pat. 118,534, Dec. 7, 1917. (Appl. No. 18,148 of 1917.)

Expansive force; Utilising an — [for pumping liquids]. H. A. Humphrey, London, and W. J. Rusdell, Dudley, Assignors to Humphrey Gas Pump Co. U.S. Pat. 1,271,712, July 9, 1918. Date of appl., May 16, 1912.

SEE Eng. Pat. 28,187 of 1911; this J., 1912, 860.

Drying china or other clay, fullers' earth, whitening, and the like; Method of and apparatus for —. W. J. Gee, London. U.S. Pat. 1,274,158, July 30, 1918. Date of appl., Apr. 6, 1915.

SEE Eng. Pat. 8892 of 1914; this J., 1915, 702.

Centrifugal separators. Eng. Pat. 118,262. See XXII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Deterioration in the heating value of — during storage. H. C. Porter and F. K. Ovlitz. U.S. Bureau of Mines, Bull. 136, 1917. 34 pages.

TESTS were made on New River and Pocahontas coals (both semi-bituminous), on Pittsburgh coal (bituminous—used for carbonisation), and on Wyoming coal (sub-bituminous). The coal was exposed to atmospheric influence by storage in piles and in bins. The quantities varied from about 300 lb. to 120 tons. A wide range of climatic conditions was secured by carrying out the experiments at several stations, including the Isthmus of Panama. Except in the case of the sub-bituminous coal the maximum loss of calorific value during exposed storage was 1.2% in the first year, and 2.6% after two years. The sub-bituminous variety deteriorated 2 to 3% in the first year and 5.5% after three years. This coal was stored in bins. Where the bin was uncovered the lumps on the surface became pulverised to a depth of 8 to 12 inches. It would seem that this powdery layer acts as a protection to the bulk of the coal, which will not then be attacked unless there be atmospheric access through the walls or floor of the bin. Further experiments showed that submersion under water effectually prevents loss in calorific value during storage of coal. It is, however, concluded that submersion under water is an unjustifiable expense, and that the loss in calorific value due to storage in exposed conditions has been commonly over-estimated. In making the calculations a formula was employed whereby the calorific value of the actual coal substance was determined, allowance being made for the content of ash, sulphur, and moisture.

—H. J.

Gas-producer; Coke and coal as fuel for —. D. J. Studler. Stahl u. Eisen, 1918, 38, 765—769.

MARKGRAF (Stahl u. Eisen, 1916, 36, 1245) found that gas from a coke producer was less effective than that from a coal producer in open-hearth steel furnaces. The author has collected data on the composition of gas from producers fired with coke and coal respectively, and shows by calculations that in general when working under similar conditions, gas from coal is more efficient in use than is that from coke, since less air is required for its combustion, and higher temperatures may be attained.—F. C. Th.

Bitumens; Device for determining the dropping point (melting point) of fats, waxes, paraffin wax, etc., and especially —. F. Dupré. Chem.-Zeit., 1918, 42, 398.

A METAL cup with a small central opening in the bottom is filled with the bitumen or the like, the latter being first melted if necessary. The cup fits into the lower end of a metal tube surrounding the lower end of a thermometer, the bulb of which is just above the top of the metal cup. The thermometer with attached metal tube and cup is mounted by means of a cork, inside a test-tube. This is placed in a beaker of water or sulphuric acid, which is heated at first strongly to within 10°–20° C. of the melting point and then so that the temperature rises about 1° per minute. The results obtained with tallow and paraffin wax agreed well with those obtained by Ubbelohde's apparatus (this J., 1905, 941), over which the new apparatus has several advantages, especially for bitumens, etc., of higher melting point.

Formation of ammonia by heating coke with calcium hydroxide. Glaser. *See* VII.

Optical dispersion of oils from an analytical point of view. Fryer and Weston. *See* XII.

PATENTS.

Fuel product and process of making same. O. F. Werner, San Jose, Cal. U.S. Pat. 1,274,480, Aug. 6, 1918. Date of appl., Aug. 30, 1917.

LAMPLACK 70 parts, a comminuted combustible material 30 parts, and lime dust 2 parts, are heated, mixed with an asphalt binder 5 parts, compressed, and cooled.—W. F. F.

Coal dust and wood charcoal powder; Treatment of — to prevent absorption of water and to hinder spontaneous combustion. N. K. II. Ekelund, Jönköping, Sweden. Ger. Pat. 306,727, Feb. 18, 1917. Under Int. Conv., Apr. 14 and Aug. 5, 1916.

THE material is well dried and mixed with finely divided peat which has been dried at a temperature of at least 100° C.—L. A. C.

Lignite, peat, etc.; Treatment of — to produce a non-hygroscopic fuel. Bertizt Ges. m. b. H., Munich. Ger. Pat. 306,880, Dec. 6, 1913.

THE material is first dried at a moderate temperature and then heated with exclusion of air to between 180° and 250° C. until evolution of water, carbon dioxide, and nitrogenous gases is complete. Esters and imides contained in the material are thus decomposed and the bituminous portion of the fuel swells and fills up the pores, preventing the absorption of water.—L. A. C.

Coke-ovens. E. Oré, Caen, France. Eng. Pat. 118,470, Sep. 7, 1917. (Appl. No. 12,866 of 1917.)

A COKE-OVEN having a number of carbonising chambers adjoining one another and separated by partitions, is provided with a number of heating flues in the partitions and end walls, each in the form of an inverted U. Each limb of the flue is provided with a gas burner at the bottom, the burners on either side being used alternately. The gas reaches the burners through refractory conduits extending from a common supply conduit at the front of the oven and provided with separate regulating valves. The air supply for each burner passes from a regenerator below the oven through a similar refractory conduit provided with a regulating damper, to the refractory block forming the burner. The hot combustion gases pass up one side of the flue and down the other side to the corresponding burner, which has its gas-supply passage closed but its air-supply passage open, so that the hot gases may pass through this passage to the complementary regenerator below the oven to heat it. When the alternate burners are brought into action the hot gases pass through the flues in the opposite direction without modifying the heating. The proportions of gas and air supplied to each burner may be adjusted independently by observing, through openings in the front of the oven, the nature of the combustion products discharged through each inoperative burner. The same type of flue may be used in an oven having no regenerator, the air being heated by contact with the hot walls, or in an oven in which the air is not preheated. In these cases only one limb of the inverted U is provided with a burner.—W. F. F.

Coke-oven; Regenerative —. E. Coppée, Brussels. U.S. Pat. 1,267,380, May 28, 1918. Date of appl., July 28, 1914.

A NUMBER of regenerators for a battery of coke-ovens are connected in parallel to a common supply flue and a common collecting flue. A pair of flues are provided between the top of each regenerator and the bottom of the corresponding oven, through which the hot gases are drawn in series from the regenerator to the uptake, and means are provided to reverse the action of the regenerators as required.—W. F. F.

Coke-oven; Reversing regenerative —. C. Still, Recklinghausen. Ger. Pat. 306,214, May 10, 1916.

THE oven has vertical heating flues to which air is supplied at the base and combustible gas at the base and through lateral openings at different heights. Any suitable gas may be used for the burners at the base of the flues and is supplied to one half of the flues during one period and to the other half of the flues when the draught is reversed. The gas supplied to the lateral openings in the flues should have a composition such that it has little tendency to pyrogenic decomposition, or it should be admixed with gases which will hinder or prevent such decomposition. It is supplied continuously, irrespective of the reversal of draught.

Coal and other materials; Distillation of — for the manufacture of motor gas and utilisation of residual products. H. K. Hiller, London. Eng. Pat. 118,522, Nov. 20, 1917. (Appl. No. 17,054 of 1917.)

COAL, lignite, wood, peat, shale, or other similar material, is distilled in a horizontal or vertical retort at about 500° C., the vapour condensed, and the residual gas stripped by oil washing and then compressed in a water-cooled compressor to a pressure of about 15 atmospheres. The whole or part of this gas is returned to the retort under pressure, and liberated just above the material in a horizontal retort, or at the temperature zone of 500° C. in a vertical retort. The gas is cooled by expansion and cools and mixes with the vapour liberated in the retort so that cracking of the vapour is prevented. It is claimed that a gas consisting mainly of methane, suitable for use in internal combustion engines, and free from vapours deleterious to balloon fabric is thus obtained.—W. F. F.

Oils from coal-gas; Extraction and fractional distillation of —. D. Marbais, Charleroi, and C. Deguide, Ixelles, Belgium. Eng. Pat. 118,730, Nov. 1, 1917. (Appl. No. 15,923 of 1917.)

COAL-GAS is passed up a tower or series of towers filled with suitable material, e.g., wood or iron shavings, etc., down which coal tar oil or anthracene oil, distilling between 230° and 250° C., is passed to absorb the benzene, etc. On leaving the bottom of the tower, the oil passes into a receiver whence it is forced by means of a pump up through a sheaf of tubes contained in a casing and then to the top of a tower similar to the first. As it trickles down the tower, the oil is debenzolised by a current of steam which enters at the bottom and passes out at the top by a pipe which leads to the casing in which it preheats the ascending oil. The steam, charged with benzene and other vapours, on leaving the casing at the bottom at about 95° C., passes into a "draining device or collector," and thence up a condenser and tower, the temperature at the top of which is about 79° C. Condensed liquid, consisting of water and "heavy oil," i.e.,

solvent naphtha and naphthalene, flows downwards into the collecting device, whence it passes into a separator; uncondensed vapour passes through a similar tower the temperature at the top of which is about 70° C. In this tower the "toluened oil or spirit," i.e., a mixture of benzene, toluene, and xylenes, separates out together with water and is drawn off at the bottom. Remaining uncondensed vapour is passed through a descending coil refrigerator, the condensed liquid consisting of benzol and water.—L. A. C.

Liquefied gas; Method of producing and separating — L. Wolf, Chicago, Ill. U.S. Pat. 1,274,970, Aug. 6, 1918. Date of appl., May 31, 1916.

HYDROCARBON gas such as distillation gas or natural gas is passed through a heat-insulated chamber, and cooled by the introduction of gaseous constituents of the mixture at such a temperature that the easily liquefiable constituents are liquefied. The gas is agitated in passing through the chamber, the liquid is separated, and the residual gas then liquefied.—W. F. F.

Motor fuel oil; Method and apparatus for producing — by distilling petroleum. C. B. Forward, Urbana, Ohio, U.S.A. Eng. Pat. 117,372, Oct. 27, 1917. (Appl. No. 15,654 of 1917.)

The apparatus is a modification of that described in U.S. Pat. 1,189,083 (this J., 1916, 883). Petroleum oil is forced through two preheater coils contained in casings through which superheated steam is passed. The steam enters the second casing at about 650° to 800° F. (about 340° to 430° C.), leaving at about 325° to 650° F. (about 160° to 340° C.), at which temperature it enters the first casing. On leaving the second preheater coil, the oil is mixed with superheated steam and sprayed through an atomiser into a separating chamber in which the heavier portions fall to the bottom as a liquid, while the lighter portions, mixed with steam, pass off at the top into a clarifier, and then, through a reducing valve, into a condenser. The pressure within the separator is about 100 to 200 lb. per sq. in., and the temperature about 400° to 600° F. (about 205° to 315° C.). —L. A. C.

Heavy hydrocarbons; Conversion of — into lighter hydrocarbons. S. Maxim, Streatham, and A. W. Crosse, Exors. of H. S. Maxim, London. Eng. Pat. 118,122, Aug. 18, 1916. (Appl. No. 11,764 of 1916.)

PARAFFIN oil is converted into a light volatile spirit and a heavy oil suitable for lubricating purposes by agitating and heating the oil under pressure, and at the same time subjecting it to electrochemical action. The process is carried out in a long steel cylinder, mounted on hollow trunnion shafts midway of its length. The interior surfaces are all heavily coated with copper. The cylinder is heated by a gas burner situated beneath, and the gas supply to the burner is regulated by a device placed on one of the hollow trunnion shafts, and actuated by the changes of pressure within the cylinder. The other trunnion shaft carries a pressure gauge. The cylinder is first charged to about a quarter of its capacity with paraffin oil, to which is added a small quantity of an electrolyte (e.g., an aqueous solution of common salt or dilute sulphuric acid) together with small pieces of zinc, or V-shaped copper-zinc couples. The air inside the cylinder is pumped out, and, if desired, hydrogen gas, which may be under high pressure, is admitted. The cylinder is then rotated over the

heater until the internal pressure is raised to about 300 to 500 lb. per sq. in., which is kept constant for several hours.—T. St.

Liquid hydrocarbons; Apparatus for obtaining — E. H. Sheets, Muskogee, Okla. U.S. Pat. 1,273,191, July 23, 1918. Date of appl., June 27, 1916.

GASES and vapours are compressed, expanded, and commingled with an oil in a mixing tank under heat and pressure, to cause combination of the gases and vapours with the liquid oil. The gases and vapours are derived partly from the oil supply tank and partly from other sources. The mixing tank is fitted with several vertical tubes, each having a bend to form return tubes which are connected with a header, whereby the heavier substances are returned to the tank and the lighter substances carried away from the tank.—T. St.

Crude-oil still. T. E. Murray, New York. U.S. Pat. 1,273,523, July 23, 1918. Date of appl., Dec. 14, 1916.

A HORIZONTAL cylindrical still is provided with scraping blades carried by hubs pivoted at the ends of radial arms attached to a longitudinal rotary shaft mounted eccentrically within the still. The hubs also carry levers which are connected to the radial arms by helical springs. Solid material on the bottom of the still is moved by the scrapers towards a delivery opening in one of the still heads.—T. St.

Crude petroleum; Apparatus for reducing — C. B. Forward, Urbana, Ohio. U.S. Pat. 1,274,405, Aug. 6, 1918. Date of appl., Sep. 25, 1916.

OIL and superheated steam are forced together into the first of a series of separator chambers fitted with means to maintain a predetermined vapour pressure therein. From the top of each chamber is a passage for vapour and at the bottom is a passage for the residuum so arranged as to discharge into the next chamber. Superheated vapour is added to the residuum in the passage, and an atomiser is provided at the discharge end of the passage.—L. A. C.

Petroleum oils; Process of treating [cracking] — Apparatus for treating petroleum oils. W. F. M. McCarty, Baltimore, Md. U.S. Pats. (A) 1,274,912 and (B) 1,274,913, Aug. 6, 1918. Date of appl., Aug. 17, 1916.

(A) PETROLEUM oil having a boiling point higher than that of gasoline is subjected to the action of superheated steam in a closed container, at a pressure of 150 lb. per sq. in., in the presence of an aqueous solution of an aluminium compound. The mixture is then allowed to settle and the aqueous solution and suspended matter withdrawn. The oil is vaporised at 400° C. and then treated at 600° C. with hydrogen and a catalytic agent, and the resulting product condensed. (B) Oil and hydrogen are passed downwards through a vertical cracking tube, and the products pass into a collecting chamber connected to the lower end and provided with draw-off pipes at top and bottom. A shaft carrying a fan extends through the lower part of this chamber and the cracking tube, and operates an agitating device in the cracking tube. Means are provided to reciprocate and rotate the shaft. The cracking tube is enclosed in a shell containing a heating tube opening into the shell at one end and connected to a flue at the other end. The shell contains a heating device, and combustion products pass through the heating tube. —W. F. F.

[*Petroleum*] oil; *Process of distilling* —. J. E. Biggins, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,274,976, Aug. 6, 1918. Date of appl., Oct. 23, 1917.

In the cracking distillation of petroleum oils, the oil is supplied at one end of a cylindrical, inclined, unobstructed chamber in which a cracking temperature and a pressure greater than atmospheric are established; air is supplied at several points along the length of the chamber to maintain a limited amount of combustion therein and keep up the heat. Vapours and gases are removed at the further end, tar and carbon are settled out from the vapours and gases, the mixture is cooled to condense any high boiling oils therein, the condensed oil is returned to the feed end of the chamber, and the residual mixture of vapours and gases is cooled to recover the cracked products.

—J. F. B.

Fuel for internal combustion engines. Explosions-Turbine-Studien-Ges.m.b.H., Berlin-Wilmersdorf. Ger. Pat. 3/6,283, Feb. 21, 1914. Addition to Ger. Pat. 298,309.

To the mixture described in the chief patent is added a substance capable of forming an emulsion with water and of higher sp. gr. than water. A fuel of approximately the same sp. gr. as water has the following composition: 500 parts of tar-oil, 500 of benzol, 200 of pentachloroethane, and 100 parts of soap solution.—L. A. C.

Lubricating oil; [Hydrogenated naphthalene as] substitute for —. Tetralin Ges.m.b.H., Berlin. Ger. Pat. 306,836, Mar. 7, 1916.

HYDROGENATED naphthalene, e.g., tetrahydronaphthalene, dekahydronaphthalene, etc., may be used for lubrication, either alone or mixed with other lubricants.—L. A. C.

Coke; Apparatus for discharging and quenching —. S. N. Wellington, Assignor to Coalite, Ltd., London. U.S. Pat. 1,274,826, Aug. 6, 1918. Date of appl., Apr. 17, 1916.

SEE Eng. Pat. 16,108 of 1915; this J., 1916, 958.

Burning pitch; Apparatus for —. G. H. H. Bølling, Christiania, Norway. U.S. Pat. 1,272,198, July 9, 1918. Date of appl., Mar. 26, 1917.

SEE Eng. Pat. 101,444 of 1916; this J., 1916, 1100.

Apparatus for redissolving separated constituents of coal tar oils or other liquids. Ger. Pat. 306,219. See III.

Nitrated product and process of making same. U.S. Pat. 1,273,568. See XXII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Recovery of solvents from air-vapour mixtures. Knoedler and Dodge. See I.

PATENTS.

Arc-light electrodes; Homogeneous — containing luminiferous substances. Rütgerswerke A.-G., Berlin. Ger. Pat. 304,461, Jan. 1, 1915.

In the operation of electric arc lamps with electrodes containing luminiferous substances, beads

of the fused material may form and solidify on the electrodes and hinder or prevent the production of an arc. According to the present patent the electrodes are provided with openings, channels, or the like, which serve to retain the fused material under the action of capillarity and prevent formation of beads of fused material at the crater and so ensure complete utilisation and consumption of the luminiferous substances.

Arc-light electrodes containing luminiferous substances. Rütgerswerke Akt.-Ges., Berlin. Ger. Pat. 306,658, Sep. 14, 1915. Addition to Ger. Pat. 304,461 (see preceding abstract).

The upper electrode is provided with a channel in the form of a circle, the diameter of which is equal to or greater than the diameter of a second lower electrode, so that should fused material be dislodged from the upper electrode it will not fall into the crater of the lower electrode.—L. A. C.

Incandescence gas mantles; Manufacture of —. Deutsche Gasglühlicht Akt.-Ges. (Auer Ges.), Berlin. Ger. Pat. 306,621, Dec. 3, 1916.

For washing the material used in the preparation of incandescence mantles, water purified by means of an aluminate-silicate (permutite), i.e., separated from salts of all but the alkali metals, may be employed in place of distilled water.—L. A. C.

Treatment of coal dust and wood charcoal powder to prevent absorption of water and hinder spontaneous combustion. Ger. Pat. 306,727. See IIA.

III.—TAR AND TAR PRODUCTS.

Phthalic anhydride from crude phthalic acid; Determination of —. C. R. Downs and C. G. Stupp. J. Ind. Eng. Chem., 1918, 10, 596—598.

A WEIGHED quantity of the sample is placed in a small glass capsule, and a glass tube, about 5.5 in. long, containing 1.5 grms. of cotton wool previously boiled with 10% sodium hydroxide solution, washed, and dried, is inserted in the top of the capsule to within 0.25 in. of the bottom of the latter. A current of air (3 bubbles per sec.) is drawn through the apparatus, the air entering at the space between the tube and the inner wall of the capsule, and the latter is then dipped in a bath of Rose metal at 220° C. The heating is continued for 45 mins., by which time the phthalic acid is decomposed and the sublimed anhydride collected in the cotton wool tower. The weight of the residue in the capsule is determined; the cotton wool is removed from the tube, boiled for 30 mins. with 45 c.c. of N/10 sodium hydroxide solution and 50 c.c. of water (the tube itself may be rinsed out with the alkali solution), an excess of N/10 acid then added, the boiling continued for 15 mins., and the mixture titrated with sodium hydroxide solution, using phenolphthalein as indicator. Each c.c. of N/10 sodium hydroxide solution is equivalent to 0.0074 gm. of phthalic anhydride.—W. P. S.

Device for determining the dropping point (melting point) of fats, waxes, paraffin wax, etc., and especially bitumens. Dupré. See IIA.

Optical dispersion of oils from an analytical point of view. Fryer and Weston. See XII.

PATENTS.

Coal-tar oils and other liquids; Apparatus for re-dissolving separated constituents of —. Dampfkessel- und Gasometerfabrik A.-G. vorm. A. Wilke und Co., Brunswick. Ger. Pat. 306,219, Apr. 1, 1917.

THE receptacle containing the tar oil or the like is provided near the bottom with a heating coil below which is an arrangement for conveying material deposited from the oil to a trough at one side. The trough is fitted with means for heating or stirring and the material therein, after being re-liquefied or dissolved may be either returned to the container or led away to be used, for example, as fuel.—L. A. C.

Phenol and allied products; Manufacture of —. R. N. Wallach, Wappingers Falls, N.Y. U.S. Pat. 1,274,961, Aug. 6, 1918. Date of appl., Jan. 12, 1918.

A CONCENTRATED aqueous solution of benzenesulphonic acid at about 100° C. is added to fused caustic alkali at about 300° C.—L. A. C.

Pyridine bases; Methods and apparatus for recovering —. F. B. Dodge, New York, and F. H. Rhodes, Philadelphia, Pa., Assignors to The Barrett Co. U.S. Pat. (A) 1,274,998, (B) 1,274,999, and (C) 1,275,000, Aug. 6, 1918. Date of appl., Jan. 17, 1918.

THE crude saturated acid solution of ammonium sulphate from the saturator in the direct or semi-direct ammonia recovery process is saturated with ammonia and the liberated pyridine bases recovered (A) by distilling the liquor so obtained, introducing ammonia into the distillate, and separating the pyridine bases by gravitation, or (B) by agitating the liquor with an oil to dissolve the pyridine bases. (C) A suitable apparatus for process (A) consists of a storage tank for the saturator liquor, portions of which are run as required into a still fitted with means for the introduction of ammonia. Connected with the still are a condenser and receiver for the condensed liquid into which ammonia may also be passed. Storage tanks connected with the receiver are provided for the condensed liquid and the separated pyridine bases. A storage tank with a filter interposed is also provided for the liquor from the still.—L. A. C.

4-Sulpho-1-aminobenzene-2-carboxylic acid; Preparation of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 307,284, Oct. 26, 1915. Addition to Ger. Pat. 296,941.

ACCORDING to the chief patent, sulphuric chlorhydrin and anthranilic acid, preferably in molecular proportions, were allowed to interact in an inert organic solvent. As an improvement, the organic solvent is replaced by sulphuric acid monohydrate, which, under the prescribed conditions, does not sulphonate the anthranilic acid.—L. A. C.

[Tar oils;] Process of manufacture of an agglutinant for coatings [from —]. J. Rosen, Paris. U.S. Pat. 1,273,927, July 30, 1918. Date of appl., July 30, 1914. Renewed May 29, 1918.

SEE Fr. Pat. 474,929 of 1914; this J., 1915, 1084.

Sulphonation of aromatic hydrocarbons; Process for the —. H. Bull, Philadelphia, U.S.A. Eng. Pat. 118,727, Oct. 23, 1917. (Appl. No. 15,421 of 1917).

SEE U.S. Pat. 1,247,499 of 1917; this J., 1918, 52 A.

p-Amino-N-methylformanilide; Process for the manufacture of —. G. T. Morgan, London. U.S. Pat. 1,273,901, July 30, 1918. Date of appl., Jan. 31, 1917.

SEE Eng. Pat. 111,321 of 1916; this J., 1918, 5 A.

Extraction and fractional distillation of oils from coal gas. Eng. Pat. 118,730. See IIA.

[Hydrogenated naphthalene as] substitute for lubricating oil. Ger. Pat. 306,836. See IIA.

Solid preparations containing cresols and mixtures of cresols and manufacture thereof by means of salts of fatty acids. Eng. Pat. 118,667. See XIXb.

Nitrated product and process of making same. U.S. Pat. 1,273,568. See XXII.

IV.—COLOURING MATTERS AND DYES.

Colours; Method of standardising the fastness of — to light. A. Robson. J. Soc. Dyers and Col., 1918, 34, 185—186.

THE method is based on the measurement of the quantity of actinic light required to produce a visible change in the tone or depth of the test-sample by noting the number of consecutively exposed standard strips of a quickly fading colour which are completely bleached under the same conditions. A dyestuff fulfilling the desired conditions for a standard is Eosine GGF (Cassella), which quickly fades to a clear white. Strips of coarse white filter paper are steeped in a 0.1% solution of Eosine, dried without rinsing, and cut into pieces 3" × ½". The samples to be tested are dyed in known proportions on cotton yarn which is wound on a cardboard strip adapted to hold 12 samples lengthwise. A stout cardboard envelope is arranged to cover one half of the row of patterns and a strip of standard Eosine paper, numbered 1, is clipped on the card. The whole is then exposed under a sheet of glass. The set of patterns is examined daily, and when the Eosine strip No. 1 has faded to a clear white, it is replaced by another, No. 2, and so on until the visible change in the test patterns is recorded. In this way a definite measure of the quantity of actinic light is obtained independent of the variations in its quality from day to day and, if necessary, the whole set may be laid aside at any time and the exposure resumed at the point where it was interrupted. It is possible also to subdivide the results into fractions of the standard to an approximate degree. The principal difficulty lies in determining the exact end-point at which the Eosine paper is completely bleached.—J. F. B.

Scarlet S3R (B) and Ponceau 3R (By); Structure of —. H. W. Stiegler. J. Ind. Eng. Chem., 1918, 10, 600.

By reduction with stannous chloride it was found that the components of the monoazo dyestuff, Scarlet S3R (Badische) are amino-R-salt (1,2-aminonaphthol-3,6-disodium sulphonate) and pseudocumidine (1,2,4-trimethyl-5-aminobenzene). The components of Ponceau 3R (Bayer) are amino-Bayer acid (1,2-aminonaphthol-8-sulphonic acid) and gamma acid (2,8-aminonaphthol-6-sulphonic acid). Scarlet S3R is thus identical with the Ponceau 3R classified as No. S3 in Schultz's tables and the constitution given by Schultz for Bayer's Ponceau 3R is incorrect.—W. P. S.

o-2'-4'-Dihydroxybenzoyltetrachlorobenzoic acid and 2,3,4-trichloro-6-hydroxyanthrone-1-carboxylic acid and some of their derivatives. W. R. Orndorff and W. A. Adamson. J. Amer. Chem. Soc., 1918, 40, 1235-1256.

THE first-named substance is best obtained by heating resorcinol (4 parts) and tetrachlorophthalic acid (5 parts) for 12-15 hours at a temperature not exceeding 131° C. (vapour of boiling xylene). It forms colourless crystals containing 2H₂O, and the dried substance at its m.pt., 227° C., decomposes into tetrachlorofluorescein and tetrachlorophthalic anhydride. On bromination in glacial acetic acid it yields *o*-3'.5'.5'-dibromo-2'.4'-dihydroxybenzoyltetrachlorobenzoic acid, yellow needles, m.pt. 211°-212° C. The triacetate of the unbrominated acid is converted by 5% alcoholic potassium hydroxide and subsequent acidification into 2,3,4-trichloro-6-hydroxyanthrone-1-carboxylic acid, colourless needles containing 2H₂O, m.pt. 279°-280° C. (anhydrous). The preceding results, and particularly the fact that the triacetates are not decomposed by boiling alcohol, are interpreted by ascribing to *o*-2'.4'-dihydroxybenzoyltetrachlorobenzoic acid the constitution

(See also J. Chem. Soc., 1918, i., 435).—C. S.

Colour reaction of mercury fulminate with phenylhydrazine. Langhans. See XXII.

PATENTS.

Azo dyes; Gray —. C. Hagemann, Leverkusen, Germany, Assignor to Synthetic Patents Co., Inc., New York. U.S. Pat. 1,270,290, June 25, 1918. Date of appl., Nov. 27, 1914. Renewed Apr. 16, 1918.

TRISAZO dyestuffs are claimed which dye cotton reddish-grey to greenish-grey shades, fast to light, and on reduction with stannous chloride and hydrochloric acid yield an aromatic aminosulphonic acid, a diamine, and an orthodiaminohydroxynaphthalenesulphonic acid. Special claim is made for the dyestuff which, on reduction, yields 4,5-dichloroaniline-2-sulphonic acid, 2 mols. of 1,4-naphthylene-diaminesulphonic acid, and 1,2-diamino-8-naphthol-6-sulphonic acid.

Azo dyestuffs capable of being chromed; Manufacture of —. O. Imray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 118,448, Aug. 28, 1917. (Appl. No. 12,348 of 1917.) Addition to Eng. Pat. 16,916, Dec. 1, 1915 (this J., 1917, 78).

SEE U.S. Pat. 1,270,325 of 1918; this J., 1918, 573 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Fabric stretching and drying apparatus. J. W. Shelton, Assignor to Tucson Steam Laundry Co., Tucson, Ariz. U.S. Pat. 1,269,751, June 18, 1918. Date of appl., Dec. 7, 1917.

THE apparatus comprises a perforated drum, a post arranged centrally within the drum, means for stretching a piece of fabric about the drum, a fan journaled around the post within the drum for forcing currents of air outward through the perforations, and means for heating the air currents.—J. F. B.

Paper-making machines. E. Partington, Westwood Park, Worcester. Eng. Pat. 118,511, Nov. 3, 1917. (Appl. No. 16,038 of 1917.)

SOME of the drying cylinders over which the web of paper first passes are maintained at a temperature higher than that of the remainder of the cylinders and sufficient to impart to the damp paper enough heat to cause the water therein to evaporate freely as it passes over the lesser heated cylinders. For instance, in a range of 16 cylinders the first five may be heated so as to raise the temperature of the web to 200° F. (93.5° C.) and the temperature of the succeeding cylinders may fall progressively at the rate of about 10° F. (5.5° C.), so that the temperature of the last is about 90° F. (32.5° C.), thus preventing baking and cockling of the paper.—J. F. B.

Writing-paper and method of making the same. S. Kuroki, Assignor to Kimpitsu Seishi Kabushiki Kaisha, Ltd., Tokyo. Reissue 14,499, July 30, 1918, of U.S. Pat. 1,234,045, July 17, 1917. Date of appl., Dec. 7, 1917.

SEE this J., 1917, 1004.

Paper-stock; Apparatus for the treatment of —. W. G. Fiske, Purfleet. U.S. Pat. 1,273,841, July 30, 1918. Date of appl., Feb. 24, 1917.

SEE Eng. Pat. 103,376 of 1916; this J., 1917, 288.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Method of standardising the fastness of colours. Robson. See IV.

PATENTS.

Dyeing machines. Fibre-treating machine. Fabric-dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,274,396, (B) 1,274,523, (C) 1,274,524, (D) 1,274,525, Aug. 6, 1918. Dates of appl.: (A) Feb. 15, (B) June 1, (C) June 15, (D) July 25, 1917.

(A) IN the dyeing machine are arranged a series of superposed removable fibre trays adjacent to each other, each tray comprising a non-perforated side wall and a foraminous bottom formed of transverse grate bars, a second chamber below the trays and a third chamber above the trays each containing a series of "upwardly disposed plates." Means are provided for circulating liquid or air through the apparatus and through a testing apparatus similar to but smaller than the main apparatus. (B) IN a receptacle are arranged a series of dyeing chambers having non-perforated sides, each chamber having a fixed foraminous bottom and a movable foraminous top capable of being adjusted and held at any desired position in relation to the bottom. The wall of each dyeing chamber contains a conduit connecting the portion of the receptacle at each end of the dyeing chamber with a testing device, and liquor is circulated by a pump through the apparatus. (C) A fibre-treating machine comprises a receptacle containing an outer foraminous cylinder with a series of spaced parallel members having projections extending upwards and downwards in the receptacle, and an inner foraminous cylinder, spaced from the outer cylinder, with tubular members connecting the openings in the inner cylinder with a supply of liquids, steam, and air. A series of sliding members is provided to abut upon a fabric wound on the cylinder so as to close all the openings

which are not covered by the fabric, also a flexible foraminous covering to enclose the wound fabric tightly on the cylinder. (b) A dyeing chamber has a removable top and a series of hollow reels capable of being revolved within the chamber on a common axis, each reel being composed of a hollow foraminous cylinder with non-perforate flanges extended outwards. A series of conduits within the hollow reels connect the ends of the reels with the inner faces of the foraminous cylinders and allow of liquid being supplied uniformly over the inner faces of the cylinders. Each reel can be revolved independently or locked against rotation, and the interior of a reel is connected with a testing device revolving with it.

—J. F. B.

Winding and dyeing machine. W. A. Alnsworth, Assignor to C. N. Mather, Grand Rapids, Mich. U.S. Pat. 1,274,972, Aug. 6, 1918. Date of appl., July 16, 1917.

THREAD or yarn is transferred from one holder in the winding machine to another, passing in close proximity to a member impregnated with colouring material, against which it is periodically pressed, so that the colouring matter is intermittently transferred to the thread in its passage through the machine. The means for applying the colour comprises a cylindrical receptacle for containing the colour liquid over which the yarn is adapted to pass, a number of wicks in the receptacle extending a short distance upwards, a shaft parallel to the receptacle, a number of collars, one for each wick, secured on the shaft, and fingers, under which the yarn is adapted to pass, projecting laterally from each collar.—J. F. B.

Clothes; Cleaning or washing — by means of benzine or benzol. B. Steffen, Cöthen. Ger. Pat. 306,257, Mar. 24, 1916.

BENZINE or benzol which has been used for cleaning clothes, with or without the addition of fresh material, is added to a mixture of dilute sulphuric acid and sodium carbonate which has been allowed to stand until effervescence has ceased, and then distilled by the direct application of steam. The distillate, after settling for 3 or 4 hours, is used again for cleansing purposes.—A. B. S.

Dyeing machines. H. M. Dudley, Philadelphia, U.S.A. Eng. Pat. 111,843, Nov. 10, 1917. (Appl. No. 16,508 of 1917.) Under Int. Conv., Dec. 5, 1916.

SEE U.S. Pat. 1,258,203 of 1916; this J., 1918, 265 A.

Manufacture of preparations of calcium halogenides and albumin. Ger. Pat. 306,978. See XX.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Formation of — by heating coke with calcium hydroxide. R. Glaser. Feuerungstechnik, 1917, 6, 3—8. Z. angew. Chem., 1918, 31, Ref., 248.

On heating coke with a large excess of calcium hydroxide the carbon completely disappears and a large quantity of hydrogen is produced. The yield of ammonia increases with the temperature, amounting at 1145° C. to 40% of the total obtainable from the nitrogen contained in the coke. On addition of nickel the yield of hydrogen is increased and the yield of ammonia reaches a maximum at 630° C., catalytic action of the nickel caus-

ing decomposition of the ammonia at higher temperatures. At 630° C. methane is also formed if nickel is present.—L. A. C.

Nitrites; Determination of —. F. Dienert. Comptes rend., 1918, 167, 366—367.

NITRITES react with hydriodic acid according to the equation: $\text{NaNO}_2 + 2\text{HI} = \text{NaI} + \text{I} + \text{NO} + \text{H}_2\text{O}$. For the estimation three flasks containing respectively 50 c.c. of 4% potassium iodide solution, 10 c.c. of N/1 sulphuric acid, and the solution of the nitrite, are connected in the order named and the air is displaced by a current of carbon dioxide. By means of this gas the potassium iodide solution is then driven over into the sulphuric acid, and then the mixture in the second flask into the third containing the nitrite solution. The liquid is then made alkaline by the addition of 10 c.c. of a 20% solution of ammonium carbonate and titrated with N/70 arsenious acid solution, of which 1 c.c. = 0.2 mgrm. of nitrous nitrogen. Care must be taken to avoid the presence of oxygen until the solution is made alkaline.—W. G.

Magnesium oxide; Influence of the temperature of burning on the rate of hydration of —. E. D. Campbell. J. Ind. Eng. Chem., 1918, 10, 595—596.

FURTHER investigation (see this J., 1909, 1036) has shown that, when it has been ignited above 1200° C., magnesium oxide requires a long time for complete hydration even when immersed in water. For example, magnesite at 1450° C., was only hydrated to the extent of 70% in 6 years. Probably 20 years, or more, would be required for the complete hydration of materials containing free magnesium oxide if burned at temperatures approaching that used for the production of Portland cement.—W. P. S.

Basic carbonates of copper. H. B. Dunncliff and S. Lal. Chem. Soc. Trans., 1918, 113, 718—722.

THE determination of the percentage of copper oxide in thirteen samples of commercial copper carbonate has given results which do not support the statement that the ordinary copper carbonate of commerce has the same composition as malachite, $\text{CuCO}_3 \cdot \text{Cu(OH)}_2$. The percentage of CuO actually found in the samples varied from 66.16 to 78.60. As the result of attempts to prepare a basic carbonate of approximately constant composition, it has been found that a substance of the formula $2\text{CuCO}_3 \cdot 5\text{Cu(OH)}_2$ is obtained when a solution of copper sulphate saturated at 14.5° C. is diluted with an equal quantity of water and mixed with a solution containing 5% of sodium carbonate and 5% of sodium bicarbonate.

—H. M. D.

Minerals [silicates]; Hydrothermal formation of —. W. J. Müller and J. Koenigsberger. Z. anorg. Chem., 1918, 104, 1—26.

EXPERIMENTS have been made to investigate what products are formed when mixtures containing K_2O , Al_2O_3 , SiO_2 , and water are heated together under pressure for varying times at temperatures from 100° to 440° C., in presence or absence of carbon dioxide. The results obtained in presence of carbon dioxide agree better with the observed order of succession of minerals in clefts and cavities in nature than do those without. Below 300° C. potassium feldspar is not formed. At 310° C. in presence of carbon dioxide only quartz is stable, but at higher temperatures aluminosilicates begin to appear. In absence of carbon dioxide zeolites are formed at 100° C., but apparently their limit of stability is reached below 300° C. The opinion is expressed, however, that in no case was a true

equilibrium obtained in the experiments below 400° C. Besides the minerals already mentioned, leucite, potassium nepheline, and pectolite were identified among the products. (See also J. Chem. Soc., Nov., 1918.)—E. H. R.

PATENTS.

Nitric acid; Process for the manufacture of —. E. Bergve, Notodden. Assignor to Norsk Hydro-Elektrisk Kvaelfstofaktieselskab, Christiania, Norway. U.S. Pat. 1,273,991, July 30, 1918. Date of appl., May 18, 1918.

HIGHLY concentrated nitric acid is prepared by causing a mixture of nitrogen tetroxide, oxygen, and water or dilute nitric acid to react together at about 70° C. and under a pressure of about 20 atmospheres.—W. E. F. P.

Tin; Oxidation of —. Production of zinc oxide. H. Maconochie, London, and D. de Ros, Greenhithe, Kent. Eng. Pats. (A) 118,664 and (B) 118,665, Sep. 1, 1917. (Appl. Nos. 12,594 and 12,595 of 1917.)

(A) PREHEATED air or oxygen is blown into or upon metallic tin which has been previously heated to the temperature at which stannic oxide is formed. Additions of preheated tin to the charge are made from time to time in such quantities that the process is operated continuously by the heat of the reaction alone. The tin oxide fume is condensed. (B) Metallic zinc or zinc-containing material, e.g. a mixture of zinc sulphide (ore) and iron, is treated as above.—W. E. F. P.

Salt; Apparatus for drying —. T. W. S. Hutchins, Middlewich. Eng. Pat. 118,712, Oct. 5, 1917. (Appl. No. 14,425 of 1917.)

A NUMBER of superposed, horizontal, cylindrical vessels, connected in series within a single casing, are provided with independent hot-air inlets and outlets communicating with common standpipes. Each cylinder has a central, horizontal shaft upon which paddles, serving as combined agitators and conveyors, are fixed, the shafts being intergeared for rotation at high speed, so that while agitated the charge is propelled along adjacent vessels in opposite directions. Means are also provided for passing into the space around the cylinders the products of combustion from the air-heating furnace.—W. E. F. P.

Peroxide of hydrogen and barium nitrate; Manufacture of —. F. Cobellis, Philadelphia, Pa. U.S. Pat. 1,273,824, July 30, 1918. Date of appl., Jan. 18, 1917.

BARIUM dioxide is treated with phosphoric acid to produce hydrogen peroxide and barium phosphate, which latter is then treated with a nitrate to form barium nitrate. The barium nitrate is converted into nitric acid and barium dioxide, the latter being used again in the process.

—W. E. F. P.

Alumite; Process for recovering the constituents of — in useful forms. H. J. Detwiller, Allentown, Pa. U.S. Pat. 1,274,145, July 30, 1918. Date of appl., Oct. 9, 1917.

POWDERED alumite is digested in boiling nitric acid and the residual silica is separated by filtration. An alkali is added to the filtrate to precipitate the alumina, which is removed by filtration. Any sulphates present are separated by adding barium carbonate, agitating, boiling, and filtering. The filtrate is made acid with nitric acid, boiled to remove the carbon dioxide, and the potassium nitrate is allowed to crystallise out.—A. B. S.

Formates and oxalates; Manufacture of —. A. Lackman, Bradford, Pa. U.S. Pat. 1,274,169, July 30, 1918. Date of appl., July 24, 1917.

SODIUM formate is made by passing granular caustic soda through a heated tubular conduit in a direction contrary to that of a current of preheated gas containing carbon monoxide. Sodium oxalate is made by heating sodium formate under similar conditions but at a higher temperature. The waste gases from both operations are used for heating the apparatus used.—A. B. S.

Potassium content of cement-kiln dust; Process for increasing the solubility of the —. R. J. Nestell, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,274,310, July 30, 1918. Date of appl., Jan. 15, 1917.

THE dust from coal-fired cement kilns is treated with water at 100° C., after which the solution is filtered and evaporated to dryness.—W. E. F. P.

Hydrofluoric acid and hydrofluosilicic acid or their salts; Manufacture of —. Rüfigerswerke-A.-G., Berlin. Ger. Pat. 306,567, Dec. 17, 1916.

IN the manufacture of hydrofluoric acid, hydrofluosilicic acid, and their salts by fusion of fluorspar or a mixture of fluorspar and silica with acid alkali sulphates, an inorganic compound, e.g., potassium sulphate, sodium sulphate, an acid alkali phosphate, sodium alum, boric acid, etc., is added to the mixture, whereby the fusion takes place more readily and the reaction temperature is reduced.—L. A. C.

Ammonium sulphite; Process for oxidising — to ammonium sulphate. H. Danneel and E. Kuhn, Basel. Assignors to Elektrizitätswerk Lanza, Gampel, Switzerland. U.S. Pat. 1,274,247, July 30, 1918. Date of appl., July 21, 1917.

SEE Eng. Pat. 105,906 of 1917; this J., 1917, 1093.

Phosphorus; Manufacture of —. H. O. H. Wenman, Bishop's Castle. U.S. Pat. 1,274,479, Aug. 6, 1918. Date of appl., Dec. 7, 1917.

VIII.—GLASS; CERAMICS.

Continuous kilns; Operation of —. R. Seydel. Tonind.-Zeit., 1918, 42, 482-483.

THE chief difficulties in the operation of a continuous kiln are due to the irregular passage of the air and hot gases through it. This is particularly the case with Hoffmann kilns in which the fuel is burned in hollow pillars formed by the bricks to be burned. If sufficient care be taken to obtain a uniform draught in various parts of the kiln, various auxiliary methods, such as boxing

tiles, are unnecessary. Difficulties arise when the finishing point and the point of collapse of the goods lie too close together; the admixture of fire-clay may help to overcome this objection. In a Hoffmann kiln with a tunnel 240—300 ft. in length, of a suitable width, with rounded ends of the same cross-sectional area as the straight portion, and provided with suitable hot air flues, the fire should travel round at the rate of 33 ft. per 24 hours. Excellent results may be obtained without difficulty in a wide kiln, with 5 or 6 feed holes, 3 ft.—4 ft. 6 in. apart, and the setting and drawing of the goods is easier than in a narrow kiln. It is important that the area of the rounded ends should be sufficiently large; the reduction usually made at this part of the kiln causes many difficulties in working. The discharge of black smoke from the chimney is an indication that fuel is being applied too soon, or that the air is not hot enough for complete combustion. Sometimes the air is too cool because too much is passing through the kiln; on reducing the quantity no smoke is produced.—A. B. S.

Hydrothermal formation of minerals [silicates].

Glass articles; Method and means for discharging molten metal in the manufacture of —. R. E. McCauley, London. Eng. Pat. 118,581, May 21, 1918. (Appl. No. 8472 of 1918.)

THE direct flow of molten metal from an extension of a glass tank to the discharge aperture is deflected by a transverse L-shaped or semi-cylindrical bridge or dam of refractory material, mounted on a vertical pipe surrounding the aperture, so that the metal is compelled to circulate about the latter before passing through. By this means the customary chilling of part of the discharged glass is avoided. The amount of glass discharged is controlled by a hollow plug as described in Eng. Pat. 113,665.—A. B. S.

Reinforced sheet glass and method of making same. Means for making reinforced sheet glass. C. and V. Shuman, Philadelphia, Pa. U.S. Pats. (A) 1,274,205 and (B) 1,274,206, July 30, 1918. Date of appl., Nov. 22, 1916.

(A) Two sheets of glass, each having a thin coating of tightly adherent celluloid, are united thereby to an interposed relatively thick sheet of celluloid, so as to form a composite sheet, sufficient heat and pressure being applied to cause the celluloid surfaces to weld. The exclusion of all air may be secured by maintaining the edges of the sheets under the influence of a vacuum. (B) A shallow sealed compartment with flexible metallic sides contains the sheets to be united and is connected to a vacuum pump. It is placed inside a larger vessel containing fluid. Means are provided for varying the temperature and pressure of the fluid as required.—A. B. S.

Glass-working. F. L. O. Wadsworth, Pittsburgh, Pa., Assignor to Ball Brothers Glass Manufacturing Co., Muncie, Ind. U.S. Pat. 1,275,178, Aug. 6, 1918. Date of appl., July 31, 1914.

SMALL quantities of glass are successively segregated from the main mass of molten metal, and the segregated portion is ejected by means of a hot gas under pressure from below the surface of the molten metal first into a receptacle, and then, when this is full, the remainder is returned to the main mass of metal at such a point that it cannot return to the segregation point until after a considerable lapse of time.—A. B. S.

Dental cements. W. S. Crowell, Philadelphia, U.S.A. Eng. Pat. 118,701, Sep. 26, 1917. (Appl. No. 13,845 of 1917.)

THE cement or filling is composed of an ordinary dental oxyphosphate of zinc powder, an orthophosphate or other salt of silver, and phosphoric acid. The silver phosphate dissolves in the solution, exhibiting characteristic germicidal, antiseptic, sedative, and coagulative properties. When the mass sets, zinc phosphate and neutral silver phosphate are formed, and further action of the silver on the tissue is inhibited. Alternatively, silver phosphate, carbonate, oxide, or hydroxide may be dissolved in phosphoric acid and the solution mixed with ordinary dental cement powder.

IX.—BUILDING MATERIALS.

Mortar; New ingredients for —. H. Kühl. *Tonind.-Zeit.*, 1918, 42, 17—18, 37—38, 53—54.

THE author reports on the use of pure hydrated lime and hydrated cement (Mühlen, Ger. Pats. 294,825, 300,397 and 301,118; this J., 1916, 1109) as ingredients of mortar. Tests of mortar made with hydrated lime (produced by passing slaked lime through an air-separator) showed no expansion. Lime-sand bricks made with this lime are much stronger than those made with ordinary slaked lime. Pure hydrated lime should also meet a widespread want in the plaster trade. The coarser silicious and aluminous particles which are removed from slaked hydraulic lime by an air-separator, yield a good bag lime when ground with quicklime, provided that the additional slaking required by such limes is properly effected. Calcined marl or cement-slurry which has been burned with an excess of lime and then hydrated by steam also produces a non-expanding mortar. The setting time varies with the percentage of lime and the mode of preparation of the material. The samples

examined passed the standard tests and also the boiling and hot water test satisfactorily. Tests of the tensile strength were also satisfactory considering the high percentage of lime. These new ingredients facilitate the preparation of new kinds of dry mortars, e.g. mortar of pure hydrated lime, cement mortars, and various mixtures for reinforced concrete.—A. B. S.

PATENTS.

Plastic material; Manufacture of a fire-resisting — and its combination with and its application to other materials for constructional purposes. R. Y. Ardagh, Hove. Eng. Pat. 118,768, Jan. 4, 1918. (Appl. No. 216 of 1918.)

SILICATE cotton or slag wool is screened to separate slag dross and other coarse particles, and is then passed over a finer sieve, through which the light wool fibres and minute mineral particles pass, but grains larger than those of a poppy seed or turnip seed are retained. The fibre is then ground in a crushing or rolling mill disintegrator, and the coarser material left on the fine sieve is ground by edge runners until it will pass completely through a fine gauze sieve. The two finely ground materials are mixed in proportions varying from 1:1 to 1:6 according to the density required, and the mixture is added to a sufficient quantity of a solution of water-glass of 70° Tw. (sp. gr. 1.35) to produce a plastic paste. The material may be moulded into sheets or columns or it may be applied as a coating to existing structural materials. The hardening may be facilitated by keeping it in a drying room at 100°–130° F. (38°–54° C.). Sawdust, cork, or other powders may be incorporated with the material.—A. B. S.

Wood; Process of preserving —. M. Landau, Berlin. U.S. Pat. 1,274,171, July 30, 1918. Date of appl., Jan. 25, 1916.

THE wood is preserved by introducing into it aqueous solutions of trioxymethylene and inorganic salts soluble in water, such as alkali fluorides.—A. B. S.

Process for increasing the solubility of the potassium content of cement-kiln dust. U.S. Pat. 1,274,310. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Chemical equilibria in the reduction and cementation of —. R. Schenk. Z. Elektrochem., 1918, 24, 248–255. (See also this J., 1907, 692; 1915, 554; 1916, 118.)

A COMPARISON of the temperature pressure equilibria in the reaction $C + CO_2 \rightleftharpoons 2CO$ with those involved in the interaction of iron and carbon monoxide, whereby the iron is carburised, shows that in this latter effect elementary carbon resulting from the decomposition of the carbon monoxide is involved. This carbon in the presence of excess of ferrite is transformed into a carbide, and hence its presence is not revealed by solution of the iron in hydrochloric acid. Equilibrium between ferrite-carbide-ferrous oxide and the oxides of carbon occurs at low pressures, the content of carbon monoxide in the gaseous phase, however, slightly exceeding that of the $C + CO_2 \rightleftharpoons 2CO$ equilibrium. The carbide thus formed is different from cementite, Fe_3C , which on heating to the Acl point is

decomposed into iron and carbon. Thermodynamical reasoning leads to the conclusion that this carbide contains less carbon than Fe_3C . In the manganese-carbon system an analogous carbide containing about 3% of carbon, corresponding to Mn_3C or Mn_2C , has been detected. The name hunsenite is suggested for this new iron carbide.

—F. C. Th.

Grey iron; Melting of — in an oil-fired furnace. K. Abeking. Stahl u. Eisen, 1918, 38, 792–795.

THE author describes the production of grey iron castings of special quality in furnaces of the oil-fired "drum" pattern without a crucible. The first cost of an installation for $\frac{1}{2}$ -ton melts is given as M.5000–6000. The furnace, which takes up little room and is equally satisfactory for other metals than iron, is much more costly to run than a cupola. The iron can be run in a very fluid condition for thin castings, and less labour is required than for a cupola. The tensile strength of the cast iron ranges from 21.7 to 30 kilos. per sq. mm. The total carbon may vary from 2.45 to 3.26%, and the sulphur from 0.062 to 0.12%. The Brinell hardness of the iron varies from 160 to 180. The charge used consists of 5–10% of steel scrap, 20% of hematite iron, and the rest foundry irons. The silicon loss during melting reaches 15–20%. The average heat lasts 2 hours.—F. C. Th.

Grey cast iron; Method for the prevention of growth in —. J. E. Hurst. Iron and Steel Inst., Sep., 1918. [Advance copy.] 5 pages.

GROWTH in cast iron when this is repeatedly heated has previously been shown to be due to the penetration of oxidising gases along the plates of graphitic carbon. If a protecting "case" could be given, so as to prevent the entry of oxidising gases, growth of the interior grey iron would be prevented. An example is given of a grey cast iron pipe subject to a temperature of 800°–900° C., which was heavily coated with rust, having been thus protected by a decarburisation of the skin produced by heating in a strongly oxidising atmosphere; the graphite was thereby replaced by the phosphide eutectic. Possible methods by which graphite might be removed without the production of cavities are by superficial decarburisation followed by the liquation of the phosphide eutectic into the remaining cavities, or by conversion of graphite into austenite solid solution at a temperature above 900° C. The author has used the decarburisation method for protecting dies and moulds from growth, i.e. by annealing at 900°–950° C. in ordinary brown rust (iron oxide) for 72 hours. The results are considerably improved by raising the annealing temperature to 975°–1000° C., but troubles from distortion are then experienced.

—C. A. K.

Malleable cast iron; Phosphorus in —. J. H. Teng. Iron and Steel Inst., Sep., 1918. [Advance copy.] 19 pages.

FOLLOWING the suggestion of Turner (this J., 1917, 793) that a poorer class of irons should be employed for making malleable castings, the effect of phosphorus varying from 0.05 to 0.5% was examined. Two series of test bars were prepared: one from a very pure American washed white iron, and the other from locally obtained pig irons, the phosphorus being added in the form of a phosphoric iron (4% P) prepared by adding red phosphorus to molten American washed white iron. The maximum stress, elongation, and reduction in area were lowered with increasing phosphorus, the most marked effect showing at about 0.25% P. When tested for malleability by bending, the bending

angle progressively decreased as the phosphorus increased, with again a marked alteration at about 0.25% P, while the hardness increased gradually, with a sudden rise on the appearance of free iron phosphide. One effect of phosphorus noticed was the larger grain size of the crystals. The approximate limit for commercial purposes is given as 0.2% P, as the ill effects of phosphorus are not appreciable until that figure is exceeded. The presence of a considerable amount of silicon and manganese is of more importance than the absence of sulphur with regard to successful annealing, and iron sulphide found in the iron ore which was used as the annealing medium is attributable to the presence of sulphur compounds in the reducing atmosphere existing in the annealing furnace.

—C. A. K.

Open-hearth furnace design: Principles of —. C. H. F. Bagley. Iron and Steel Inst., Sep., 1918. [Advance copy.] 19 pages.

THE author discusses the design of open-hearth furnaces from both scientific and practical points of view, and expresses the view that scope for improvement exists in British practice. The most important requirement is an exceedingly high temperature, as the output and efficiency are functions of the average temperature attainable rather than of the heat units generated, and the view is expressed that the object of regenerating is not so much the economical recovery of heat units, but rather that the highest flame temperature may be reached. With the same object in view the gas and air used for combustion should be dry.

—C. A. K.

Open-hearth furnaces: Utilisation of waste heat from — for the generation of steam. T. B. Mackenzie. Iron and Steel Inst., Sep., 1918. [Advance copy.] 24 pages.

FLUE gases from the regenerators of an open-hearth steel furnace are passed through a water-tube boiler for the generation of steam. A water-sealed valve is arranged to send the gases either to the boiler, or direct to the chimney, and a fan discharges the gases from the boiler economiser back into the chimney. Explosion doors are required to prevent accidents when the furnace valves are thrown over. From a series of trials made, the average weight of steam generated per ton of ingots was 987.5 lb., and under more favourable conditions it is thought that at least 1200 lb. of steam would be obtained. Assuming a steam consumption at the mill engines of 3200 lb. per ton of ingots, the saving in boiler fuel is considerable. The average temperatures of the gases in one test were: entering boiler, 577° C.; entering economiser, 303° C.; entering fan, 171° C.—C. A. K.

Basic steel; Influence of some elements on the tenacity of —. A. McWilliam. Iron and Steel Inst., Sep., 1918. [Advance copy.] 13 pages.

AN attempt has been made to devise a formula on a rational basis which would give reasonably correct results for the tensile strength of steels within and above the range of the British Standard Specifications for Structural Steels (28 to 33 tons per sq. in.). Assuming values for the various elements that are fairly well established for the lower tempers, the strength of absolutely pure iron was estimated to be about 38,000 lb., or 17 tons per sq. in. The unit of any element is taken as 0.01%. The results were obtained by trial and error on a very large number of steel tests made during inspection work. The effects of the several elements may be summarised. Phosphorus adds 1000 lb. per unit, carbon 800 lb. (1000 lb. where the carbon

is over 0.4%); silicon 120 lb.; manganese 100 lb. (150 lb. where the carbon is over 0.4%). Sulphur is ignored. The formula now employed for obtaining the maximum load per sq. in. is:—

$$ML = 38,000 + [800 + 4(C - 20)]C + 120Si + [100 + 2(C - 20)]Mn + 1000P.$$

The formula has given good results for a large number of Indian basic steels, and the agreement with Harbord's basic Bessemer series is also good, but hitherto the results have not been as favourable for acid steels as for basic steels.—C. A. K.

Steel: Cooling of — in ingot and other forms. J. E. Fletcher. Iron and Steel Inst., Sep., 1918. [Advance copy.] 40 pages.

MOLTEN steel, however carefully melted, contains a considerable volume of gas in suspension, and the finishing additions to the bath lead to reactions which continue in the fluid metal even when in the ladle and ingot mould. From observations of the metal in ingot moulds and in sand moulds for steel castings, the author concludes that the shrinkage is closely connected with the escape and reduction in volume of the occluded gas on cooling. If the imprisoned gas is allowed to escape from the metal under a liquid head, the cavities are filled in and contraction of the casting is lessened. The primary crystallites forming on the surface of the mould expel the gas which they contained when liquid into the interior mother liquor, and the gas travels to the mass centre of the ingot, the segregatory constituents being driven in the same direction. By a too rapid freezing of the metal, piping is produced. The lines of most rapid freezing and cooling follow the paths of steepest temperature gradients, these being the bisecting planes of the mould sides and those bisecting the base angles, and time teeming and the efficacy of slow pouring in comparatively heavy moulds are only now being generally understood. It is evident that the temperature gradient is an index to the chilling effect; the steeper the gradient, the more carbide is retained in the metal. It might be expected that with steels of higher carbon percentage than 0.5%, the outer skin would be hard, due to the chilling action of the mould, but since the temperature gradient rapidly decreases as the axis is approached, this hardening is removed by an annealing effect unless the mean temperature of the ingot falls rapidly to below the A_c point.—C. A. K.

Molybdenum [in ferromolybdenum]: Estimation of — as lead molybdate. R. Strebing. Oesterr. Chem. Zeit., 1917, 20, 226–228. Z. angew. Chem., 1918, 31, Ref., 278.

FROM 0.5 to 1.0 grm. of ferromolybdenum is decomposed by fusion with 10 grms. of sodium peroxide in an iron crucible, the melt dissolved in warm water, boiled for a short time, and washed into a 500 c.c. flask. After settling, 100 c.c. of the liquid is neutralised with acetic acid, the solution boiled for a short time, and the following freshly prepared solutions quickly added in succession: (1) 2–5 grms. of lead acetate and 2 c.c. of acetic acid in 50 c.c. of water, and (2) 10 grms. of ammonium acetate in the same quantity of water. Boiling is continued for a few minutes and the solution is then allowed to stand for six hours, after which it is filtered through filter-pulp. The precipitate is washed with about 200 c.c. of ammonium acetate solution, and is then transferred, together with the moist filter-pulp, to a beaker in which it is heated to boiling with 20 c.c. of dilute nitric acid, after which a solution of 10 grms. of ammonium acetate and 5 c.c. of dilute acetic acid in 50 c.c. of water is added. The solution is boiled for 1 to 2 mins., filtered after 12 hours, and the residue, after having

been washed with hot ammonium acetate solution until the filtrate is free from lead, is dried, incinerated at the lowest possible temperature, ignited, and weighed as $PbMoO_4$.—L. A. C.

[Gold] ores; Roasting of sulphotelluride — for amalgamating and cyaniding. A. L. Blomfield and J. M. Trott. Amer. Inst. Min. Eng., Sep., 1918. Eng. and Min. J., 1918, 106, 400—404.

THE Golden Cycle Mining and Reduction Co., Colorado Springs, treats Cripple Creek ores practically free from base metals, containing 1.8% of sulphur, and varying amounts of lime (1.6—5%). The ore is bedded, the beds (class A, 66% of total ore, not more than 2% CaO ; class B more than 2% CaO) being made as large as possible; It is crushed in ball mills so that not more than 30% remains coarser than 10-mesh, and roasted for 6 hours in lignite-fired Edwards Duplex furnaces; the hearth of the furnace slopes $\frac{1}{2}$ in. per foot towards the discharge end, which causes the ore to move forward under the action of the rabbles. The roasting results in the formation of calcium sulphate which, unless an excess of air is maintained, becomes converted into sulphide. The sulphate is very troublesome in the subsequent leaching, as it crystallises out and causes the pulp to set, but if the roasting is conducted at a temperature above $870^\circ C$, calcium sulphate is rendered practically insoluble. The calcine traverses a cooling-hearth and is then ground in Chilean mills under cyanide solution; the pulp is passed through a Dorr bowl classifier, and the sand and slime are cyanided separately.—W. R. S.

[Gold.] The Crowe system of de-aerating cyanide solutions. T. B. Crowe. Amer. Inst. Min. Eng., Sep., 1918. Eng. and Min. J., 1918, 106, 413.

VACUUM precipitation has been adopted at the Portland Gold Mining Co.'s mill (Colorado Springs). A continuous vacuum is applied to the cyanide solution during its flow to the precipitation presses, whereby the dissolved air is removed from the liquid. The zinc consumption has thus been halved, and that of cyanide nearly so, because the addition of solid cyanide at the head of the precipitation plant is no longer necessary for satisfactory gold precipitation.—W. R. S.

Radium ores; Metallurgical treatment of —. R. B. Moore. Amer. Inst. Min. Eng., Sep., 1918. Eng. and Min. J., 1918, 106, 410—412.

THE average radium content of commercial ores is 5—10 mgrms. per ton. The treatment aims at first obtaining a barium radium sulphate concentrate, which may be effected by several methods. The ore may be boiled with alkaline carbonate solution or fused with the solid salt, whereby uranium and vanadium are rendered soluble. The residue is leached with hydrochloric acid and the solution precipitated with sulphuric acid. In the Radeliffe process the ore is fused with saltcake, the fusion product crushed and agitated with water, and the liquor separated from the heavy unattacked material. The turbid solution is left to settle, when it deposits sulphates of barium, lead, and radium. In the U.S. National Radium Institute, the material is boiled with 40% nitric acid, in which the alkaline earth sulphates are appreciably soluble. The hot acid solution is rapidly filtered under pressure through a plate of "filtros" or alundum forming the bottom of an earthenware filter set in a steel shell. The filtrate deposits barium and radium sulphates. The sulphate concentrate, which should carry 1 mgrm. of radium per kilo., is reduced by ignition with charcoal, and

the resulting sulphide dissolved in hydrochloric acid. Further concentration is effected by fractional crystallisation of the mixed chlorides, and, later on, of the mixed bromides from acid solution, the radium accumulating in the less soluble fractions.—W. R. S.

Zinc content of furnace ashes. O. Mühlhaeuser. Metall u. Erz, 1918, 15, 259—265.

THE zinc content of the ashes from the muffles varied from 2.9 to 14.5%, the total loss being on the average about 10%. The ashes near the throat of the muffle contained about 35% Zn, compared with an average of just over 4% in the hinder part. The zinc present varied from 2.9 to 57% along the whole length of the muffle, due chiefly to the lower temperature at the throat, but also to the deposition of zinc oxide formed by the action of air entering between the muffle and the condenser. The zinc content of the ash increases but slowly at first from 3 to 6% over a distance of 105 cm. from the rear end of the muffle, finally rising rapidly in the last 20 cm. of the muffle. The zinc is present in the ashes chiefly as oxide and sulphide; if iron is present the latter is reduced to metal.—F. C. Th.

Aluminium pig; Remelting of — in the electric furnace. D. D. Miller. Chem. and Met. Eng., 1918, 19, 251—254.

AN electric remelting furnace in use at the works of the United States Aluminium Co., at Massena, N.Y., U.S.A., is of the stationary resistance type, rated at 500 kilowatts, and designed for single-phase, 25-cycle operation. It consists of a rectangular metal casing, having a door at each end and three rabbling doors on the side opposite the tap-hole. The hearth is bowl-shaped and capable of holding 3 or 4 tons of molten metal. Resistor troughs, rectangular in cross-section and open at the top, made of highly refractory carbide mixed with a binder, are disposed along each side of the interior; these are filled with resistor material (finely broken carbon or graphite) and supported on separate brick piers. Current enters the trough through large copper terminals attached at the ends; and the heat generated is radiated mainly to the furnace roof and deflected thence to the hearth. The temperature is regulated by voltage control, for which purpose a special regulating transformer, an indicating and integrating wattmeter, and a thermo-electric pyrometer are provided. The voltage actually employed ranges from 500 down to 240; and, with continuous operation, the furnace has a capacity of 1 ton per hour, and a daily output of 20 tons. As compared with oil- and coal-fired furnaces previously employed, the metal losses, particularly with alloys containing volatile constituents, are much smaller and the products more uniform; the cost of electric power also compares very favourably with the increased cost of fuel oil. In addition to saving space per ton of metal melted, the electric furnace requires less labour, is cleaner and healthier for the workmen, and offers obvious advantages in the control of atmosphere, temperature, and application of heat.—W. E. F. P.

Antimony in the Transvaal. N. M. Galbreath. J. S. Afr. Assoc. Anal. Chem., 1918, 1, [2], 9—10.

THE deposits of the Murchison Range (N.E. Transvaal) contain up to 10% Sb, and 4 dwt. An per ton.* Part of the latter is apparently enclosed in the stibnite, as cyaniding does not give a good extraction. Lignation on sloping triangular hearths has been tried; one-third of the antimony is thus ex-

tracted, while the bulk of the gold remains in the residue. Flotation was fairly successful on an experimental scale (*cf.* this J., 1915, 964); 8 lb. of lubricating oil and 9 lb. of sulphuric acid were used, the extraction reaching 60% for antimony and 80% for gold.—W. R. S.

Chromium and carbon. High temperature investigations. XI. O. Ruff and T. Foehr. *Z. anorg. Chem.*, 1918, 104, 27—46.

A CHEMICAL and metallographic study of the alloys of carbon and chromium. Alloys containing up to 8.5% carbon are completely soluble in hot 24% hydrochloric acid. The two constituents present are free chromium and a carbide Cr_3C_2 . By continued extraction of the powdered alloy with cold 2N hydrochloric acid until all the free chromium is dissolved, the carbide is obtained in the form of silvery crystals, sp. gr. at $248^\circ/4^\circ \text{C.}$ 6.915, m.p.t., 1665°C. , which are not attacked by *aqua regia*. An alloy containing 8.5% carbon consists of practically pure carbide. Microscopic sections of this alloy show a uniform mass of crystals, but alloys less rich in carbon show crystals of the carbide embedded in a eutectic. Alloys with over 8.5% carbon contain no free chromium, but show the presence of two carbides, Cr_3C_2 and Cr_7C_3 , and a variable amount of graphite. The carbon content of alloys saturated with carbon increases as the temperature of preparation is raised. At 1840°C. the carbon content is 12.42%, at 2567°C. 23.12%, the excess of carbon at higher temperatures being present as graphite. When these alloys are treated with hot 24% hydrochloric acid the carbide Cr_3C_2 dissolves, whilst a residue of graphite and Cr_7C_3 is left behind. After extraction of the graphite the carbide Cr_3C_2 remains in a pure condition. Its sp. gr. at $21.3^\circ/4^\circ \text{C.}$ is 6.683 and its melting point $1890^\circ \pm 10^\circ \text{C.}$ The existence of these acid-resisting chromium carbides explains the valuable properties of other alloys, particularly those of iron, containing chromium and carbon. The carbide Cr_3C_2 has strong reducing properties at high temperatures (above 1850°C.), reducing magnesia, alumina, and zirconia. Chromium alloys saturated with carbon boil at about 2570°C. under 8—14 mm. pressure, the vapour being pure chromium. (See also *J. Chem. Soc.*, Nov., 1918.)—E. H. R.

White metal; Determination of antimony in —. E. W. Kaiser. *Metall.*, 1917, 320—321. *Z. angew. Chem.*, 1918, 31, Ref., 230.

ONE GRM. of drillings is dissolved in 20 c.c. of concentrated sulphuric acid, cooled, and diluted with 50 c.c. of water. 15 c.c. of concentrated hydrochloric acid is added and the solution boiled till all smell of chlorine has disappeared. 100 c.c. of water is added when cold and 15 c.c. of a solution containing per litre 67 grms. of manganese sulphate, 135 c.c. of phosphoric acid (sp. gr. 1.7), and 130 c.c. of concentrated sulphuric acid. The mixture is titrated with N/10 permanganate standardised against pure antimony powder. If tin and copper are present ($\% \text{Sn} \times 0.4 + \% \text{Cu} \div 100$ c.c. is deducted from the result of the titration. Arsenic may be subtracted directly. If more than 0.3% iron is present the preliminary solution must be made in hydrochloric acid and potassium chlorate and the antimony precipitated from the diluted solution by an iron rod, filtered off, and treated as above. For the estimation of tin the antimony is precipitated and filtered off through a filter strewn with iron filings. Carbon dioxide is passed through the filtrate, which is titrated with iodine and starch.

—F. C. Th.

Heat-content-temperature curves of metals. F. Wüst, A. Meuthen, and R. Durrer. *Stahl u. Eisen*, 1918, 38, 177—781.

MEASUREMENTS were made of the total heat, specific heat, latent heat, and heat of transformation of many metals with the following results:—

$$\text{Total heat} = a + bt + ct^2; \text{ mean specific heat} = at^{-1} + b + ct; \text{ true specific heat} = b + 2ct.$$

For iron the A2 change at 725° — 785°C. is accompanied by a heat change of 6.56 cal. per grm., A3 by 6.47, and A4 at 1405°C. by 1.94. The transformation in manganese at 1070° — 1130°C. results in an evolution of 24.14 cal. per grm., in nickel at 320° — 330°C. of 1.33, and in cobalt at 950° — 1100°C. of 14.70 cal. The hysteresis in iron at A3 is 8°C. , A2 and A4 both being reversible. The following latent heats of fusion in cal. per grm. were determined:—Tin 13.79, bismuth 10.23, cadmium 10.81, lead 5.47, zinc 23.01, antimony 38.86, aluminium 93.96, silver 26.02, gold 15.87, copper 40.97, manganese 36.65, nickel 56.08, cobalt 58.23, and iron 49.35.

PATENTS.

Thomas [steel] process; Method of improving the —. F. Wüst, Aix-la-Chapelle, Germany. Eng. Pat. 107,770, July 5, 1917. (Appl. No. 9736 of 1917.)

IN the application of the Thomas process a large amount of iron is burnt and lost in the slag during the oxidation of the phosphorus. It is proposed to add a proportion of completely refined metal from a previous charge to the pig iron. The process is then carried out in the usual way, the burning of the carbon being greatly accelerated by the high initial temperature of the charge. During the blowing the high heat of oxidation of phosphorus is distributed over the whole charge, and excessive rise in temperature at the end of the heat is thus avoided, with consequent saving of metal, and it becomes possible to produce economically steel of a

lower phosphorus content than hitherto. Part of the molten completely refined metal may be left in the furnace for the following charge, or may be added to the charge in a preliminary pig-iron mixer.

—C. A. K.

Magnetic material [iron and iron alloys] for use in static transformers and other electrical apparatus; Treatment of —. A. F. Berry, London. Eng. Pat. 118,425, June 30, 1917. (Appl. No. 9489 of 1917.)

IRON or an alloy of iron or other material in which high magnetic properties are desired is subjected to an alternating magnetising and demagnetising force whilst kept under a vacuum and in a heated condition. This may be done by surrounding the material with an insulated coil of wire through which an alternating current is passed. In the manufacture of such material it may be subjected in vacuum to such force during the time it is molten and afterwards when in a heated solid condition.

—C. A. K.

Ingot moulds for the manufacture of steel. B. Talbot, Middlesbrough. Eng. Pat. 118,488, Sep. 27, 1917. (Appl. No. 13,966 of 1917.)

THE enlarged head of an ingot mould is lined with a slag (c.g. blast-furnace slag) which will melt at the casting temperature of steel. The slag lining may be formed by casting molten slag round a core of suitable section, fitted inside the recessed head of the mould, or may be separately cast, with or without the addition of iron or steel turnings and fitted in the solid form. When the liquid steel is poured into the mould, the face of the slag lining fuses and, floating on the top of the steel, causes the steel to remain liquid in the centre, and the segregation of impurities to be brought nearer to the top of the ingot. A cover plate of slag may be used to retain further the heat in the head of the mould.

—C. A. K.

Cast-iron articles; Art of permanently heat-expanding —. W. A. Knapp, Assignor to C. Schwartz, Washington, D.C. U.S. Pat. 1,274,896, Aug. 6, 1918. Date of appl., Oct. 28, 1915.

IRON castings are uniformly heated throughout to a temperature between 1400° and 1600° F. (760°–870° C.), and then cooled immediately, the treatment being repeated until the desired degree of expansion is attained.—C. A. K.

Silicon-iron alloys; Prevention of graphite precipitation in the manufacture of acid-resisting high —. Maschinenfabrik Esslingen, Esslingen. Ger. Pat. 306,001, Nov. 20, 1917.

IN the manufacture of silicon-iron castings containing 12–18% Si for acid-resisting purposes, low-carbon iron and ferrosilicon are melted simultaneously in cupolas, tapped, and mixed in a ladle, and the castings poured.—F. C. Th.

Heat treatment; Indicating the condition of steel, iron, or other magnetisable metal during —. L. W. Wild and E. P. Parfield, London. Eng. Pat. 118,732. (Appl. Nos. 16,072, Nov. 3, 1917, and 1905, Feb. 1, 1918.)

IN the apparatus described in Eng. Pat. 112,891 of 1917 (this J., 1918, 153 A), a compensating device is provided to prevent the indications being affected by small accidental fluctuations in the current supplied to the primary coil.

Cementation of iron and steel. W. Beyer, Leipzig-Stötteritz. Ger. Pat. 306,937, Nov. 7, 1917.

THE article to be carburised is embedded in carburising material within a hollow body and the latter is heated in a salt or metal bath.—F. C. Th.

Blast-furnace stoves. T. G. Wrightson, J. M. Ringquist, and Head, Wrightson and Co., Ltd., Thornaby-on-Tees. Eng. Pat. 118,203. (Appl. Nos. 17,368, Nov. 24, 1917, and 8586, May 23, 1918.)

A BLAST-FURNACE stove is provided with an outer annular combustion chamber, the brickwork at the bottom being of undulatory form, whereby dust-collecting spaces are formed. The gaseous fuel and hot blast mains extend around the combustion chamber and have a number of connections into it.

—C. A. K.

Open-hearth furnaces; Cooling of interior of —. W. Reichpietsch, Bochum. Ger. Pat. 305,757, Mar. 17, 1914.

THE roof and arches are cooled by air blown in through nozzles above the gas port. The air channels are placed between the top and lower layers of the roof.—F. C. Th.

Crucible melting furnaces. L. C. Harvey, and The Morgan Crucible Co., Ltd., Battersea. Eng. Pat. 118,346, Sep. 8, 1917. (Appl. No. 12,912 of 1917.)

THE inner cover of a crucible melting furnace, of the type having both outer and inner covers, is made in sections which slide on the top of the inner lining to allow of ready removal from above the furnace chamber. The furnace base is hinged, and has a ribbed dish upon its upper surface to facilitate the removal of spilled metal.—C. A. K.

Arc soldering; Electrodes for —. A. B. Pescatore, London. Eng. Pat. 118,296, May 21, 1917. (Appl. No. 7329 of 1917.)

AN electrode is made of varying cross-section so that on fusion of the electrode the arc travels around its circumference and causes an even fusion of metal. The slag-forming coating also adheres better during the handling of the electrode. Such an electrode may be formed by wrapping an iron or steel wire spirally around a steel rod, by twisting two wires round one another, by twisting a single rod of polygonal section, or by cutting a screw thread on a round electrode. The electrode so made may be coated by dipping it in an agglutinant and spraying with a suitable material in the form of powder.—C. A. K.

Electrode; Spark-plug — and alloy therefor. W. B. Driver, East Orange, N.J. U.S. Pat. 1,274,395, Aug. 6, 1918. Date of appl., May 15, 1918.

THE electrodes in a spark-plug are composed of an alloy of nickel, manganese, and chromium, substantially in the proportions; Mn 2%, Cr 3½%, Ni (or Ni and Co) 94½%.—C. A. K.

Platinumising metal surfaces; Process of —. B. B. Crombie, Port Chester, N.Y. U.S. Pat. 1,274,995, Aug. 6, 1918. Date of appl., Mar. 29, 1918.

THE surface of the metal to be plated is cleansed by mechanical and chemical means and a paste consisting of 1 part of ammonium platinochloride, 8 of potassium tartrate, and 3 parts of distilled water is applied by means of a friction pad until sufficient platinum has been deposited. The plated article is then treated electrolytically in a bath consisting of 12 parts of platinum chloride, 4 of ammonium platinochloride, and 84 parts of water, using the article as cathode and pure platinum foil as anode.—L. A. C.

Zinc; Process for utilising the residues obtained in the distillation of — R. Köhler and O. Bailin, Liplne, Germany. U.S. Pat. 1,275,045, Aug. 6, 1918. Date of appl., Jan. 3, 1914.

A NEW charge of zinc ore is placed above the glowing residue, containing a portion of the flux, of a previous charge. Metallic vapours are driven from the residue by the passage of a strong current of air, and are partly condensed by the new charge, which is afterwards heated and distilled, the blast having been shut off.—C. A. K.

Powdered ores, flue dust, etc.; Furnace for drying, calcining, and sintering — W. Schumacher, Berlin. Ger. Pat. 306,032, Feb. 9, 1916.

A VERTICAL furnace is fitted with double walls, the inner wall being so arranged, i.e., constructed of superposed steeply inclined air-cooled or water-cooled hollow iron plates, that gases may pass through, but the material, which is fed in at the top, is prevented from passing out of the central shaft. Hot gas, e.g. air, is led into the space between the walls at the bottom of the furnace and, by means of partitions, is caused to flow three times through the central shaft before it leaves the furnace at the top. Two or more furnaces may be arranged in series.—L. A. C.

Briquettes [of metals or mineral "fines"]; Machines for manufacture of — General Briquetting Co., New York. Assignees of T. Gilmore, jun., Brooklyn, N.Y., U.S.A. Eng. Pat., 113,279, Feb. 5, 1918. (Appl. No. 2082 of 1918.) Under Int. Conv., Feb. 6, 1917.

Metal-sheet coating apparatus for use in plant for plating such sheets. Means for cooling metal sheets discharged from the furnaces of plating plant. Furnaces for heating metal sheets. The Thermic Plating Process Co., Inc., Assignees of W. E. Watkins, New York. Eng. Pats. 116,292, 116,294, and 116,295, June 11, 1917. (Appl. Nos. 9069, 9071, and 9072 of 1918.) Under Int. Conv., June 10, 1916.

Rabble-arms for use in mechanical roasting furnaces. Huntington, Heberlein, and Co., Ltd., and H. C. Bingham, London. Eng. Pat. 118,564, Mar. 13, 1918. (Appl. No. 427 of 1918.)

Ore-floatation process. H. C. Colburn, Colorado Springs, and E. A. Colburn, Denver, Colo. Re-issue 14,497, July 30, 1918, of U.S. Pat. 1,226,062, May 15, 1917. Date of appl., Jan. 19, 1918.

SEE this J., 1917, 721.

Separation of mixed metallic sulphides. L. Bradford, Broken Hill, N.S.W. U.S. Pat. 1,274,505, Aug. 6, 1918. Date of appl., Oct. 22, 1914.

SEE Eng. Pat. 21,880 of 1914; this J., 1915, 1256.

XII.—FATS; OILS; WAXES.

Oils; Optical dispersion of — from an analytical point of view. P. J. Fryer and F. E. Weston. Analyst, 1918, 43, 311–317.

The optical dispersion of oils was determined by means of a Zeiss-Iulfrich refractometer, using a hydrogen tube with a pressure of about 2 mm., the red and blue rays from which corresponded with the C and F lines of the spectrum. The readings were made at 40° C. (except in the case of Japan wax and spermaceti, 56° C.), and the refractive power calculated according to the formula:—

$$\omega = \frac{n_D - n_c}{n_D - 1}.$$

It was found that nearly all the oils

and fats examined gave very similar dispersions (0.0186–0.0207), with the exception of coconut oil (0.0167), linseed oil (0.0218), and tung oil (0.0371). Palm-kernel oil and butter fat also gave comparatively low figures (0.0180 and 0.0182 respectively), and the results indicate that the dispersion is lowered by the presence of glycerides of low molecular weight, and increased by that of glycerides of highly unsaturated fatty acids. The difference between the dispersion of coconut oil and palm-kernel oil is comparatively greater than the difference between the refractive indices. The dispersive power is reduced by about 0.00002 for each increase of 1° C. Free acidity in the oil has but little influence on the optical dispersion. Linseed oil exposed in a thin film for 28 hours showed an increase in dispersive power from 0.0218 to 0.0223, whilst niger seed oil exposed for 50 hours showed an increase from 0.0198 to 0.0204. Heat-polymerisation of these two oils caused a large increase in the refractive index and a notable decrease in the dispersive power, especially in the case of linseed oil. In the case of tung oil, however, there was pronounced progressive reduction both of the refractive index and of the dispersion on heating. Hence it would appear that the thickening and solidification of tung oil on heating must be due to some factor other than polymerisation. In the case of hydrocarbon oils little variation was observed in the dispersions of petroleum distillates of lower b.pt. (petroleum naphtha, paraffin oil, solar oil, and American "mineral sperm"), but a higher fraction (American "engine oil") showed a pronounced increase. Members of the benzene series show relatively high dispersions, which are reduced by the addition of the side-chain in toluene and xylene, whilst turpentine closely resembles fatty oils both in refractive index and dispersive power.—C. A. M.

Fish oils. W. Fabriou. Chem. Umschau, 1917, 57. Chem.-Zeit., 1918, 42, Rép., 136.

THE statement by the author, made nearly twenty-five years ago (this J., 1893, 938), that fish oils contained jecoric acid, $C_{18}H_{30}O_2$, an isomer of linolenic acid, has been confirmed by the examination of sardine oil. Besides the more unsaturated acid, clupanodonic acid, $C_{18}H_{28}O_2$, discovered by Tsujimoto (this J., 1906, 818), this oil contains jecoric acid and probably also a less unsaturated fatty acid. The occurrence in natural fats of fatty acids containing an odd number of carbon atoms is still open to doubt, but later investigations make it appear possible that asellinic acid, $C_{17}H_{32}O_2$, isolated by the author from liver oils, is an individual acid and not a mixture of stearic and palmitic acids.—W. P. S.

Opium wax. J. N. Rakshit. Analyst, 1918, 43, 321—322.

Ox extracting 200 grms. of dry powdered opium with successive portions of cold petroleum spirit, shaking the united extracts with 5 successive portions of 4% hydrochloric acid until the aqueous extract ceased to give a precipitate with Mayer's reagent, and neutralising, drying, filtering, and evaporating the petroleum spirit extract, 14.35 grms. of a brown sticky mass was obtained. This opium wax had the following characters:—Iodine value, 152.5; Reichert value, 2.0; saponif. value, 114.5; and unsaponifiable matter, 28.7%, with iodine value, 138.5, and m.pt. about $86^{\circ}C$. Opium wax is insoluble in water, and nearly insoluble in methyl alcohol, ethyl alcohol, and glacial acetic acid, sparingly soluble in acetone and amyl alcohol, but soluble in carbon tetrachloride, chloroform, petroleum spirit, turpentine, and ether, and readily soluble in carbon bisulphide, benzene, and toluene. Nitric acid makes it slightly browner, sulphuric acid dark brown, and a mixture of hydrochloric and nitric acids, pale yellow.—C. A. M.

Soap: Distillation method for the determination of water in —. R. Hart. J. Ind. Eng. Chem., 1918, 10, 598—599.

A QUANTITY of the soap sufficient to yield about 3 c.c. of water is distilled with the addition of its own weight of "red oil" or oleic acid and 150 c.c. of water-saturated xylene; 85 c.c. of distillate is collected in a receiver already containing 5 c.c. of water-saturated xylene. The condenser is washed out with the xylene and the washing added to the receiver; the latter consists of a cylinder holding about 120 c.c. and constricted at the bottom to form a tube about 4 cm. long and graduated in tenths of a c.c. The volume of the water collected is read off after 30 mins.; a slight turbidity usually noticed in the xylene layer does not affect the results obtained.—W. P. S.

Device for determining the dropping point (melting point) of fats, waxes, paraffin wax, etc., and especially bitumens. Dupré. See IXA.

Occurrence of carotin in oils and vegetables. Gill. See XIXA.

PATENTS.

Oils, etc.; Steaming —. A. Lowenstein, Chicago, Ill. U.S. Pat. 1,274,175, July 30, 1918. Date of appl., Aug. 28, 1916.

OILS, fats, waxes, fatty acids, and like products are subjected to the action of steam superheated at a low pressure (not exceeding 6 lb. per sq. in.) to a temperature above $500^{\circ}F$. ($260^{\circ}C$). The process may be used for distilling fatty acids and for deodorising glycerides.—A. B. S.

Decoloriser [for fatty oils]. P. A. Boeck, New York, Assignor to Celite Products Co., Los Angeles, Cal. U.S. Pat. 1,272,197, July 9, 1918. Date of appl., June 14, 1917.

A DECOLORISING agent, especially suitable for use in refining fatty oils, is composed of a mixture of calcined kieselguhr and fullers' earth, preferably in equal proportions. The kieselguhr, in addition to its own decolorising action, increases that of the fullers' earth, in that the effective surface of the latter is increased. Moreover, in admixture with kieselguhr, finer grades of fullers' earth can be used than hitherto, without danger of clogging the filter.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Cobalt [in varnishes, paints, etc.]; Colorimetric determination of —. E. G. Jones. Analyst, 1918, 43, 317—319.

SMALL quantities of cobalt (0.01 to 0.1%) in varnishes, zinc oxide paints, etc., may be rapidly determined colorimetrically by means of a solution of α -nitroso- β -naphthol as used by Atack (this J., 1915, 641), the effect of moderate quantities of many other metals being eliminated by the addition of ammonium citrate solution (500 grms. in 250 c.c. of water plus 500 c.c. of ammonia solution of sp. gr. 0.880). In the case of varnishes the ash from a weighed quantity of the sample is treated with strong hydrochloric acid, followed by *aqua regia*, and later by hydrochloric acid to remove the nitric acid. The solution is evaporated to dryness, the residue dissolved in hot water with the addition of a few drops of hydrochloric acid, and the solution made up to definite volume. An aliquot portion is treated with 5 c.c. of the ammonium citrate solution, the mixture diluted nearly to 100 c.c., 5 c.c. of the reagent added, and the colour compared with that given by different quantities of a standard cobalt solution mixed with the same amounts of ammonium citrate and α -nitroso- β -naphthol. Copper when present in more than a trace should be removed by means of hydrogen sulphide, and nickel separated by dimethylglyoxime, the excess of oxime being subsequently destroyed. Manganese when present in much greater quantity than the cobalt may be removed to a sufficient extent by boiling with sodium bismuthate, and the cobalt estimated in the filtrate.—C. A. M.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation researches. B. J. Eaton. Agric. Bull. Fed. Malay States, 1918, 6, 315—316.

AS has already been observed for crêpe rubber, the use of even five times the minimum quantity of acetic acid for coagulation has very little effect in retarding the rate of vulcanisation of matured "slab" rubber; the use of sodium bisulphite in the preparation of rubber also causes a comparable slight retardation in the rate of vulcanisation of slab and crêpe rubbers; the addition of sodium bisulphite is ineffectual in the production of pale-coloured slab rubbers by the present method, as darkening occurs on allowing the coagulum to mature in the open. During the washing and crêping of slab rubber little or none of the natural accelerators of vulcanisation is lost, rubber which had been "wormed" without washing vulcanising even a little more slowly, possibly on account of its invariable tendency to "spot disease." The

use of alum as a coagulant on certain small holdings is regarded with disfavour, the period of optimum vulcanisation being found to range from $1\frac{1}{2}$ to $4\frac{1}{2}$ hours in a number of samples of sheet rubber thus produced.—D. F. T.

PATENTS.

India-rubber and the like; Treatment of —. W. J. Mellers-Jackson, London. From Morgan and Wright, Detroit, Mich., U.S.A. Eng. Pat. 118,305, Aug. 9, 1917. (Appl. No. 11,473 of 1917.)

THE extent to which rubber expands during vulcanisation is indicative of the degree of vulcanisation attained and the most efficient vulcanisation is effected at the point when the expansion has reached a maximum. An apparatus is described with which it is possible to observe the expansion corresponding with various periods of vulcanisation of a cylindrical test-piece of a rubber mixing. A chart is constructed for each mixing giving the expansion for various periods of vulcanisation and steam pressures, and with the aid of this it is possible to pre-determine the extent of expansion which the mixing will show at the desired degree of vulcanisation. The method is particularly applicable to articles vulcanised in moulds which, for this purpose, must be provided with a gauge to record the expansion.—D. F. T.

Rubber or other materials or articles; Apparatus for the drying or heat treatment of —. F. Moore, Birmingham. Eng. Pat. 118,394, Mar. 19, 1918. (Appl. No. 4801 of 1918.)

ARTICLES of rubber or other material are attached to a circular rotating framework, a segment of which is covered by the oven, the remainder acting as a cooling area. The tray is rotated intermittently, the intervals allowing for the removal of articles after treatment and for the attachment of other articles; the period of complete rotation should suffice for a single heat treatment. The number of rotations is recorded by a counting device.—D. F. T.

Latex; Process and apparatus for treating —. E. M. Sloenn, Medan, Sumatra, Assignor to General Rubber Co. U.S. Pat. 1,268,638, June 4, 1918. Date of appl., Feb. 23, 1917.

LATEX is coagulated in a chamber provided with a spiral partition, so that the coagulum is obtained in a spiral strip instead of a compact slab.—D. F. T.

Latex; Process for treating — and products obtained thereby. E. M. Sloenn, Medan, Sumatra, Assignor to General Rubber Co. U.S. Pat. 1,268,639, June 4, 1918. Date of appl., Feb. 23, 1917.

IN the preparation of rubber from latex, the coagulation process is assisted by the addition of the enzyme coagulase.—D. F. T.

Latex; Process of coagulating — and product thereof. E. M. Sloenn, Medan, Sumatra, Assignor to General Rubber Co. U.S. Pat. 1,270,887, July 2, 1918. Date of appl., Feb. 23, 1917.

RUBBER is obtained from latex by the addition of a metalloid compound adapted to form an insoluble material in the latex whilst substantially free from any tendency to accelerate coagulation.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Glues; Determining the comparative melting points of — as a measure of the jelly strength. C. F. Sammet. J. Ind. Eng. Chem., 1918, 10, 595.

THE dried glues are ground and 1-grm. portions of the samples which pass a 20-mesh sieve but are retained by a 40-mesh sieve are placed in small beakers with 10 c.c. of water at 10° C. and soaked for 1 min. A small quantity of each is then transferred to a smooth brass plate, 6 in. by 15 in., and $\frac{1}{16}$ in. thick; the glue particles are placed about 3 in. from the end of the plate and a portion of each, about the area of five pin heads, is separated by means of a spatula and pushed to within 2 in. of the end. The plate is then dipped to a depth of 0.5 in. in water at 40° C. The poorer grades of glue melt and slide rapidly down the plate whilst the better grades melt some time before a sliding effect occurs. If desired, a small disc of copper foil may be pressed on each heap; the copper adds weight and slides quickly at the first indication of the jelly melting. Comparison with standard glues shows that the melting point may be taken as a measure of the jelly strength.—W. P. S.

XVI.—SOILS; FERTILISERS.

Soil extracts and physiological solutions; Determination of ammonia and nitric nitrogen in —. B. S. Davisson. J. Ind. Eng. Chem., 1918, 10, 600—605.

AMMONIA is determined by the aeration method, 250 c.c. of the extract being treated with 2 grms. of sodium oxalate, 10 grms. of sodium carbonate, and a few drops of oil, and the aeration continued for 3 hrs. at the rate of 1080 litres of air per hr. The residual solution is then treated with 5 c.c. of concentrated sulphuric acid, boiled, 5 c.c. of Stutzer's cupric hydroxide reagent is added, the mixture filtered, the filtrate boiled for 30 mins. with the addition of sodium hydroxide, and the nitrate then reduced with Devarda's alloy. The resulting ammonia is determined by distillation. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Water hyacinth as a source of potash. F. W. F. Day. Agric. Bull. Fed. Malay States, 1918, 6, 309—314.

EXAMINATION of the ash of the water hyacinth (*Eichornia crassipes*), a local weed of rapid growth, shows that this constitutes approximately 10—15% of the sun-dried plant and consists essentially of potash (25% expressed as K_2O or 40% as KCl) together with sodium and magnesium chloride, sulphate, and carbonate and a little phosphate; the ash of the stalks is richer than that of the other parts in soluble potassium salts. The variable composition of the plant with respect to potash content as reported earlier (Finlow and Maclean, this J., 1918, 253 A), is largely due to fine particles of silt, etc., incorporated in the roots or adhering to the plant; the greater the ash the smaller its percentage of potash. The plant should be of value not only as a nitrogenous, potassic, and phosphatic fertiliser, but also as a source of potash for other purposes.—D. F. T.

Phosphates [in fertilisers]; Gravimetric determination of —. W. R. Mummery. Analyst, 1918, 43, 324.

THE following modification of Ullmann's method of determining phosphates is recommended, especially for the analysis of guano and fertilisers.

After the digestion, the nitric acid solution should be filtered prior to being made up to standard volume. Phosphomolybdates are precipitated at 60° C. and the mixture allowed to stand 30 mins. at 60° C. before filtering. Magnesium ammonium phosphate is precipitated at 80° C. and allowed to stand for 3 hours at the ordinary temperature. It is essential to use precipitating and washing reagents of the prescribed strength. (See also J. Chem. Soc., Nov., 1918.)—C. A. M.

Sugar cane; Fertiliser experiments with —. J. Mirasol y Jison. Philippine J. Sci., 1918, A, 13, 135–143.

On planting Los Baños white cane in a clay loam soil, it was found on treating 15 plots, each of 450 sq. metres area, with different fertilisers and combinations of them that the highest purity of the juice was obtained with potassium sulphate alone and with a complete fertiliser containing potassium sulphate, sodium nitrate, and double superphosphate; whereas the purity of the juice was lowered to a considerable extent with double superphosphate in combination with nitrogen either in the form of ammonium sulphate or sodium nitrate, the effect on the percentage of sucrose in the juice running parallel with that on the purity of the juice. Ammonium sulphate in combination with potassium sulphate or with double superphosphate produced the highest yield of cane, dried blood and potassium sulphate apparently having the contrary effect, though an increased yield of cane was shown not to result in a greater nett amount of 96° sugar. Tests carried out with complete fertilisers indicated sodium nitrate to be superior to ammonium sulphate as a source of nitrogen for the cane, and it is concluded that under the conditions of the tests the highest financial returns would be obtained with a complete fertiliser containing potassium sulphate, sodium nitrate, and double superphosphate (the nitrogen, potash, and phosphoric acid being in the ratio 8 : 6 : 8).—J. P. O.

XVII.—SUGARS; STARCHES; GUMS.

Oxidases; Presence and functions of — in the sugar cane. R. Narain. Agric. J. India (Special Science Congress Number), 1918, 47–64.

EXTRACTS of the oxidases present in the various parts of the sugar cane were prepared by crushing the sliced parts in a mortar with sterilised sand and filtering the expressed liquids through a Buchner funnel or a porcelain filter candle. The extracts retained their activity for several months in the presence of chloroform (5% by vol.), toluene and ether both having an inferior preservative effect. Oxidases were found to be more active in the upper than in the lower part of the stem of the cane; in the rind than in the pith; in the pith from the upper than in that from the lower parts; in the nodes than in the internodes; and in the open flat portion of the leaf than in the sheath or curled-up part or in the stem of the leaf. They were extremely sensitive to the reaction of the medium, the activity (as indicated by the guaiacum test) diminishing as the acidity of the extract increased; the presence of acid in quantity such as is normally present in the plant is not, however, harmful to sugar-cane oxidase. It is possible that the activity of the oxidases in the growing plant may be controlled by variations in the acidity of the sap, since it was found both in unripe and in fully developed canes that the acidity is distinctly lower in the afternoon when the sun is strongest and other photosynthetic processes are in progress than

in the earlier part of the day. Whereas Moore and Whitley (Biochem. J., 1909, 4, 136) found the activity of oxidases to be completely destroyed by the action of reducing agents, the author found that the activity of cane oxidases is inhibited only for a time by hydrogen sulphide, there being a subsequent recovery, which is more rapid in the presence of chloroform. Similarly, on boiling cane oxidase extracts their activity, though at first apparently destroyed, is actually only suspended temporarily, and gradually returns almost to its original value. Even after boiling twice, there is a recovery. Further, it was possible to obtain the guaiacum reaction from extracts of cane leaves which had been dried at 100° C. during 6 hours, while even the ash of these leaves gave a faint but distinct indication with the same reagent. It is considered that it is impossible longer to regard oxidases (or at least those present in the cane) as enzymes, as has hitherto been done, since they are not destroyed by heat, and experiments indicate that they are not capable of acting upon a practically indefinite amount of substrate.—J. P. O.

Levulose; Determination of — in the presence of aldoses. Herzfeld and Lenart. Zentr. Zuckerind., 1918, 68, 227. Chem.-Zeit., 1918, 42, Rep., 135.

A QUANTITY of the substance containing about 1 grm. of levulose is dissolved in water, the solution clarified with lead acetate, diluted to 100 c.c., and filtered; 50 c.c. of the filtrate is then inverted (Clerget-Herzfeld method), cooled, and treated with bromine, 1 c.c. of the latter being added for each grm. of aldose present. The mixture is shaken occasionally for 24 hrs., whereby the aldoses, and these only, are oxidised. The excess of bromine is evaporated on the water-bath, the mixture neutralised, then treated with a few drops of acetic acid, diluted to 100 c.c., and the levulose determined from the reducing power of the solution, using the Höfig-Jesser table.—W. P. S.

Fertiliser experiments with sugar cane. Mirasol y Jison. See XVI.

PATENT.

Vegetable glue; Process of manufacturing — [from starchy materials]. V. G. Bloede, Catonsville, Md. U.S. Pat. 1,273,571, July 23, 1918. Date of appl., Dec. 17, 1917.

AMYLACEOUS matter is heated with water containing a neutral salt to or near the boiling point until a smooth and homogeneous paste is formed. The salt must be one having the property of increasing the solubility of the starch granules, but must not prevent or materially retard the action of "starch-reducing" enzymes or bacilli. The paste is cooled and is then acted upon by "starch-reducing" enzymes or bacilli until of the desired consistency. The vegetable glue so obtained is evaporated at a low temperature to solid form.—T. St.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes; Chemical composition and formation of —. XV. Further experiments with *B. acidilactis* (*Streptococcus lactis*). H. Euler and O. Svanberg. Z. physiol. Chem., 1918, 102, 176–184.

THE evolution of carbon dioxide during lactic acid fermentation by *Streptococcus lactis* (see Euler and Griese, this J., 1917, 1283) is not confirmed. The fermentation of lactose by *Streptococcus lactis* is

Inhibited by sodium phosphate, whereas the action of *B. casei*, E., was found to be accelerated. Sodium lactate also exerts an inhibiting action on lactic acid fermentation.—H. W. B.

Refractometer; Use of the dipping — [in the examination of alcoholic liquids]. W. W. Randall. J. Ind. Eng. Chem., 1918, 10, 629—630.

In determining the alcoholic strength of a solution by means of the immersion refractometer, low readings are obtained when the usual metal cup is used for holding the solution. This appears to be due to the conduction of heat from the atmosphere to the contents of the cup through the metal parts of the instrument after the cup and its contents have been brought to the proper temperature for the observation. Alteration in temperature of the liquid does not take place when small glass beakers are used in place of the metal cups. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Action of ozone on artificial culture media and on various bacteria, yeasts, and moulds. Heise. See XIXb.

PATENTS.

Beer; Manufacture of non-alcoholic malt — L. Block, Mamaroneck, N.Y. U.S. Pat. 1,271,269, July 2, 1918. Date of appl., July 10, 1915.

In the production of a non-alcoholic malt beverage, the alcohol is removed, under the influence of a vacuum, at the temperature of, and immediately after the main fermentation. The liquid is then cooled, subjected to a secondary or aging fermentation (kräusening), carbonated, and filtered.

Cooling plates for continuous rectification apparatus. Eng. Pat. 110,910. See I.

XIXA.—FOODS.

Cream; Pasteurisation of sour, farm-skimmed — for butter making. O. F. Hunziker, Spitzer, H. C. Mills, and H. B. Switzer. Purdue Univ. Agric. Exper. Stat., Bull. No. 208, 1917, 20, 1—76. Bull. Agric. Intell., 1918, 9, 695—697.

PASTEURISATION at 145° F. (63° C.) for 20 mins. was more effective than rapid (flash) heating at 165° F. or 185° F. (74° C. or 85° C.); it improved the quality of the butter, even of that made from inferior cream, and did not materially alter the composition of the fat. During storage the lactose decreased and the acidity increased, but not proportionately, whilst there was always a certain amount of decomposition of proteins, the changes being least in butter made from pasteurised cream.

—W. P. S.

Butter fat; Method for the detection of foreign fats in — A. Seidenberg. J. Ind. Eng. Chem., 1918, 10, 617—621.

A METHOD described previously by the author (this J., 1917, 1128) for fractionating fats and oils may be adapted to the detection of foreign fats in butter fat. Ten grms. of the sample is dissolved in a 150 c.c. graduated cylinder (27 cm. high and 3.1 cm. diam.) in a mixture of ether, 90, and absolute alcohol, 10 parts by vol., sufficient of the solvent being added to make the total volume 96 c.c. The cylinder is closed by a rubber stopper through which pass a thermometer and two tubes, one short and the other reaching nearly to the bottom of the cylinder. By raising or lowering the thermometer, the surface of the liquid is brought between the 100 and 102 c.c. marks, and air, previously passed through absolute alcohol, is drawn through the

solution at such a rate that it is reduced to about the 60 c.c. mark in not more than 12 or less than 8 mins. The temperature is maintained between 10° and 15° C. by means of a bath of warm water. The volume of the solution is noted at the point where a distinct turbidity appears, the aspiration is stopped, the solution filtered rapidly, and the precipitated glycerides weighed. With pure butter fat the turbidity is produced when the volume is between 44 and 68 c.c. (of 100 samples examined 94 gave a turbidity at a volume between 50 and 60 c.c.). The maximum insoluble residue found with pure butter fat was 0.449 gm. If the volume of the solution at the turbidity point is more than 68 c.c., the presence of tallow, lard, or hydrogenated fat is indicated; when the volume is lower than 44 c.c., coconut stearine is probably present.

—W. P. S.

Carotin in oils and vegetables; Occurrence of — A. H. Gill. J. Ind. Eng. Chem., 1918, 10, 612—614.

It was shown previously that the peculiar bluish-green reaction of palm oil with acetic anhydride containing a trace of sulphuric acid was due to carotin (this J., 1917, 336). Carotin has now been found to be present in maize, pumpkin, orange peel, flax seed, mustard seed, black sesame seed, butter fat, tallow, grass, and carrots, but not in rape seed, white sunflower seed, turnip, safflower, or turmeric.

—W. P. S.

Eggs; Determination of loosely bound nitrogen in — as ammonia. N. Hendrickson and G. C. Swan. J. Ind. Eng. Chem., 1918, 10, 614—617.

TWENTY-FIVE grms. of the sample is mixed in a cylinder with 100 c.c. of water, 75 c.c. of alcohol, 1 gm. of sodium fluoride, 2 c.c. of 50% sodium carbonate or potassium carbonate solution, and 1 c.c. of kerosene, and air is blown through the mixture for 4 hrs.; the air containing the ammonia is passed through absorption vessels containing standard acid, and the ammonia is determined volumetrically or colorimetrically. Frozen eggs yield about 0.003% of nitrogen as ammonia, but the quantity increases with incipient decomposition. Magnesium oxide or sodium hydroxide cannot be used in place of potassium or sodium carbonate in the method.—W. P. S.

XIXB.—WATER PURIFICATION; SANITATION.

Ozone; Action of — on artificial culture media and on various bacteria, yeasts, and moulds. R. Heise. Arb. Kaiserl. Gesundh.-Amt, 1917, 50, 418. Chem.-Zeit., 1918, 42, Rep., 137.

AN ozone concentration of 3 mgrms. per cub. metre of air was sufficient to kill in 3–4 hrs. more than 95% of the bacteria present as individuals on the surface of a culture medium. The ozone penetrates with difficulty into the medium and into masses of bacteria, consequently colonies were hardly affected. Low temperature favoured the action of the ozone. Similar results were obtained with yeasts, which proved to be slightly more sensitive. Both the spores and the mycelia of moulds growing on the surface of a medium were killed, but any mycelium below the surface was not killed. From these experiments it is concluded that only a partial destruction of organisms present on the flesh of animals preserved in cold storage can be expected by the use of ozonised air, but sufficient to improve the keeping qualities of the meat.—J. H. J.

PATENTS.

Distilling and sterilising liquids, especially water; Apparatus for —. M. C. Rimmer, London. Eng. Pat. 118,482, Sept. 18, 1917. (Appl. No. 13,413 of 1917.)

THE apparatus consists of a spherical boiler with a neck and a side tube at the water level. The neck projects through the base of a dome-shaped condenser. Part of the cooling water leaving the condenser passes through a tube with a regulating cock and drips into a cup at the end of the side tube of the boiler. The water condensed inside the dome collects on the base of the dome and runs away by a pipe in the base. The boiler is supported on a sand bath and is heated by a Bunsen burner or other means. The boiler and condenser are made of earthenware, glass, or other non-metallic material.—J. H. J.

Filters; Method of operating and cleansing —. K. Morawe, Berlin-Friedenau. Ger. Pat. 304,658, Sep. 9, 1916.

A WIND-BOX is provided on the clean water side of the filter. During filtration uniform pressure is maintained over the whole surface of the filter. To cleanse the filter, water under pressure is forced by means of the compressed air in the wind-box upwards through the filtering material so as to agitate it and free it from sludge. Compressed air from an outside source may be introduced to aid in the cleansing of the filter. The wash water from the upper part of the filter flows downwards through a central pipe, provided with a jet device, back to the wind-box, and is thus circulated repeatedly through the filtering material, so that only a comparatively small quantity of wash water is required.

Cresols and mixtures of cresols; Solid preparations [disinfectants] containing — and the manufacture thereof by means of salts of fatty acids. C. A. Cofman-Nicoresti, Snaresbrook. Eng. Pat. 118,667, Sep. 3, 1917. (Appl. No. 12,621 of 1917.)

A DISINFECTANT in the form of solid tablets is prepared by heating a mixture of crude or refined cresol with salts of fatty acids (e.g. sodium stearate or animal soap) with or without pressure. Formalin and suitable colours and perfumes may be added if desired. The tablets are dissolved in water or alcohol as required.—L. A. C.

Water; Process of softening —. H. Heller, Assignor to Oelwerke Stern Sonneborn A.-G., Cologne, Germany. U.S. Pat. 1,273,857, July 30, 1918. Date of appl., Nov. 13, 1914.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; Polarimetric determination of — in opium. J. N. Rakshit. Analyst, 1918, 43, 320–321.

SIXTEEN grms. of dried opium powder is triturated with 4 grms. of slaked lime until thoroughly mixed, 50 c.c. of water freshly saturated with ether is added, and, after complete admixture, 110 c.c. of the same water is added, and the whole mixed for 15 mins. It is then filtered through a covered filter, and 100 c.c. of the filtrate shaken in a separating funnel for at least 3 mins. with 100 c.c. of ether saturated with water. The separated aqueous layer is shaken in another funnel with an equal volume of the saturated ether, and this process of extraction again repeated. Finally 51 c.c. of the separated aqueous liquid is placed in a 250 c.c. flask with 1.5 c.c. of strong hydrochloric acid, shaken with 10 grms. of well-washed dried animal charcoal for 10 mins., and filtered. The filtrate is examined in the polarimeter, and the amount of morphine calculated, taking the specific rotation of anhydrous morphine in dilute hydrochloric acid to be -127° at 25° C. with white light. The result is multiplied by 1.05 as a correction for the increase in volume due to the addition of acid, and 51 c.c. instead of 50 c.c. taken as representing

5 grms. of opium. The use of water saturated with ether and ether saturated with water prevents the formation of emulsions in the separation of the calcium morphinate from the other alkaloids.

—C. A. M.

α-Oxycinchonine. E. Léger. Bull. Soc. Chim., 1918, 23, 328–335.

α-OXYCINCHONINE behaves towards hydrobromic acid as do cinchonine and its isomers, the product being hydrobromocinchonine and a certain amount of the isomers of cinchonine. Similarly with sulphuric acid *α*-oxycinchonine yields the same isomers of cinchonine as does cinchonine itself. It is concluded that the so-called *α*-oxycinchonine is really *α*-oxydihydrocinchonine, the vinyl side chain of cinchonine being replaced by the group $\text{CH}_2\text{CH}(\text{OH})$.

—W. G.

Alkaloids of the Calabar bean. VII. Degradation by successive iodomethylations of the nuclei of eserine and geneserine. M. and M. Polonovski. Bull. Soc. Chim., 1918, 23, 355–356.

With a view to elucidating further the constitution of eserine and geneserine certain derivatives of this series have been subjected successively to the action of methyl iodide and alkali and a number of new derivatives are described. (For details see J. Chem. Soc., Nov., 1918.)—W. G.

Alkaloids of the Calabar bean. VIII. Hydrogenation in the eserine, geneserine, and ψ -geneserine series. M. Polonovski. Bull. Soc. Chim., 1918, 23, 356–361.

ESERINE and its derivatives when reduced by zinc and hydrochloric acid yield dihydro-derivatives. Geneserine and its derivatives on reduction yield first the corresponding eserine derivatives and then their dihydro-derivatives. (See further J. Chem. Soc., Nov., 1918.)—W. G.

Theobromine; Determination of —. W. O. Emery and G. C. Spence. J. Ind. Eng. Chem., 1918, 10, 604–606.

ABOUT 0.1 gm. of the sample together with an equivalent amount of sodium acetate is dissolved by heating with 2 c.c. of glacial acetic acid, the solution is diluted with 5 c.c. of hot water and transferred to a 100 c.c. flask containing 50 c.c. of N/10 iodine solution. 20 c.c. of saturated sodium chloride solution and 3 c.c. of concentrated hydrochloric acid are added, the mixture filtered after about 15 hrs., and the excess of iodine titrated in an aliquot portion of the filtrate. The quantity of theobromine is calculated from the amount of iodine used to form insoluble theobromine periodide, $\text{C}_7\text{H}_8\text{N}_4\text{O}_2 \cdot \text{HI} \cdot \text{I}_2$. The method may be used when sodium salicylate is present. (See also J. Chem. Soc., Nov., 1918.)

—W. P. S.

Digitalis; Relative activity of separated portions of —. E. L. Newcomb and C. H. Rogers. Amer. J. Pharm., 1918, 90, 580–588.

SELECTED clean digitalis (compare this J., 1918, 322 A) when tested physiologically on guinea-pigs was found to be twice as active as the arbitrary standard of Reed and Vanderkleed, and about 12% more active than average digitalis when tested by the intravenous method on cats. Relatively the Reed and Vanderkleed standard was much lower than the accepted standard for digitalis by the cat method. The petioles of digitalis were from one fourth to one fifth as active as the entire leaf, and the greatest physiological activity was

shown chiefly in those parts of the leaf where photosynthetic activity was most pronounced. Dirt siftings separated in cleaning the drug had in one instance one fifth to one sixth of the activity of the clean drug, but in the other cases infusions of the dirt siftings produced effects on cats and guinea-pigs not characteristic of digitalis. The hairs of the digitalis leaf contain, at most, a relatively small amount of the glucosidal principles of the drug.

—C. A. M.

Citral; Modification of the Hiltner method for determining —. C. E. Parker and R. S. Hiltner. J. Ind. Eng. Chem., 1918, 10, 608–610.

THE addition of 1% of oxalic acid to the alcoholic *m*-phenylenediamine hydrochloride solution used as the reagent in Hiltner's colorimetric method (this J., 1910, 172) prevents the formation of a green or blue colour given by certain lemon and orange oils and extracts, and the normal yellow coloration due to citral is obtained. (See also J. Chem. Soc., 1918, ii., 377.)—W. P. S.

Cholesterol; Energetic oxidation of — by nitric acid. A. Windaus. Z. physiol. Chem., 1918, 102, 160–165.

ACETIC, succinic, methylsuccinic, and *α*-methylglutaric acids and dinitroisopropane are among the products of oxidation of cholesterol by nitric acid. Acetone, hydroxyisobutyric acid, methyl isohexyl ketone, and octane have previously been obtained, and the author points out that all these substances may be regarded as derived from an iso-octyl side-chain in cholesterol.—H. W. B.

Potassium guaiacolsulphonate; Identification and determination of —. S. Falkin. J. Ind. Eng. Chem., 1918, 10, 610–612.

To identify potassium guaiacolsulphonate in admixture with gums, resins, alkaloids, etc., a portion of the sample is mixed with dilute hydrochloric acid, filtered, and a portion of the filtrate is tested for sulphate; another portion of the filtrate is heated with the addition of sodium peroxide, and the still acid solution again tested for sulphate. In the absence of sulphate in the first test, subsequent formation of sulphate by oxidation indicates the presence of sulphonate. A red coloration is obtained when a portion of the filtrate is rendered alkaline and treated with a drop of diazotised *p*-nitroaniline solution, should the sample contain guaiacolsulphonate. A further test consists in distilling a solution of the sample with syrupy phosphoric acid containing a small quantity of sodium chloride; in the presence of guaiacolsulphonate, the distillate gives a green coloration with ferric chloride and reduces ammoniacal silver nitrate solution. To determine potassium guaiacolsulphonate, the substance is oxidised by repeated evaporations with hydrochloric acid, bromine, and nitric acid, and the resulting sulphuric acid precipitated as barium sulphate.—W. P. S.

Hexamethylenetetramine tablets; Evaluation of —. W. O. Emery and C. D. Wright. J. Ind. Eng. Chem., 1918, 10, 606–608.

THE tablets are powdered and 0.5 gm. is boiled for 15 mins. under a reflux condenser with 100 c.c. of water and 25 c.c. of 10% hydrochloric acid; the solution is then cooled and diluted to 250 c.c. 10 c.c. of this solution is added to a mixture of 20 c.c. of potassium mercury iodide solution (mercuric chloride, 10, potassium iodide, 30, acacia, 5 grms.,

water, 200 c.c.) and 10 c.c. of 15% sodium hydroxide solution cooled previously to 0° C. The reaction proceeds according to the equation:
 $\text{CH}_2\text{O} + \text{K}_2\text{HgI}_4 + 3\text{KOH} = \text{Hg} + \text{HCOOK} + 4\text{KI} + 2\text{H}_2\text{O}$.
 The separated mercury is determined iodometrically by adding to the mixture 10 c.c. of 40% acetic acid and 20 c.c. of N/10 iodine solution and titrating the excess of iodine with thiosulphate solution. Each c.c. of N/10 iodine solution is equivalent to 0.001167 gram. of hexamethylenetetramine.

—W. P. S.

Organic chemical reagents. I. Dimethylglyoxime.
 R. Adams and O. Kamm. J. Amer. Chem. Soc., 1918, 40, 1281—1289.

METHODS of manufacturing the less common organic reagents are being thoroughly worked out at the University of Illinois and full details of the processes will be published with the object of inducing manufacturers to take up the production of the more useful of such reagents. The present paper deals with the production of dimethylglyoxime (1 kilo. in 8 hours) by Gandarin's method (this J., 1908, 1083). The removal of coloured impurities in dimethylglyoxime is effected by treating its saturated solution in 8% sodium hydroxide solution with an excess of concentrated ammonium chloride solution; the colourless precipitate of dimethylglyoxime is filtered off immediately. The purification is repeated if necessary.—C. S.

Naphthalene [; Some arsenic] derivatives [of —]. A. A. Boon and J. Ogilvie. Pharm. J., 1918, 101, 129—130.

α -NAPHTHYLAMINE arsenate, $\text{C}_{10}\text{H}_7\text{NH}_2\cdot\text{H}_3\text{AsO}_4$, colourless needles, melting at 170° C., which become blue on exposure to the air or when heated above 165° C., is obtained when a mixture of α -naphthylamine and arsenic acid is recrystallised from hot water. When one part of α -naphthylamine is heated with 2½ parts of the above arsenate for a short time at 200° C., a purple tarry mass is obtained containing 1-aminonaphthyl-arsinic acid together with a purple amorphous substance, $\text{C}_{15}\text{H}_{11}\text{NO}$, which can be extracted from the tar with concentrated sulphuric acid. (See also J. Chem. Soc., 1918, i., 461.)—D. F. T.

Opium war. Rakshitt. See XII.

Method for the separation and quantitative estimation of the lower alkylamines in presence of ammonia. Weber and Wilson. See XXIII.

PATENTS.

Tooth stopping preparations; Manufacture of —.
 V. V. J. Andresen, Copenhagen, Denmark. Eng. Pat. 110,154, Aug. 15, 1917. (Appl. No. 11,744 of 1917.) Under Int. Conv., Sep. 30, 1916.

A MIXTURE of eugenol, formaldehyde solution, and alum is heated to 110°—125° C. in an open vessel and the gelatinous product is worked with a suitable amount of zinc oxide into a stiff paste. The resulting mass possesses the advantage for dental practice that it does not merely serve as a mechanical stopping, but also causes a local dentine anaesthesia and sterilises the parts under treatment.

—D. F. T.

Camphor; Purifying —. E. C. R. Marks, London. From E. I. Du Pont de Nemours and Co., Wilmington, Del., U.S.A. Eng. Pat. 118,489, Sep. 28, 1917. (Appl. No. 14,034 of 1917.)

CRUDE camphor is heated in a closed vessel at 300°—500° F. for 30—90 mins., whereby the organic

impurities, such as camphor oil, are converted into substances differing in volatility from camphor or are rendered non-volatile or insoluble. Lime may be introduced to absorb water. The product is dissolved in alcohol, light petroleum, or other organic solvent with the aid of heat, filtered, and cooled in pans, when pure camphor crystallises out, or pure camphor is recovered from the product by sublimation.—J. H. J.

Hydrogenisation and dehydrogenisation of carbon compounds. C. Bosch, A. Mittasch, and C. Krauch, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,271,013, July 2, 1918. Date of appl., June 4, 1914.

IN the hydrogenation and dehydrogenation of carbon compounds a catalyst is used consisting of co-precipitated nickel and a compound, difficult to reduce, of oxygen with a metal which is capable of forming only a weak basic oxide (e.g. aluminium oxide). The product has the catalytic properties of nickel reduced at about 300° C.—L. A. C.

Urea; Preparation of compounds of — with a calcium salt. Knoll und Co., Ludwigshafen. Ger. Pat. 306,804, Sep. 8, 1916.

UREA is combined with calcium chloride (1 mol. CaCl_2 to 4 mols. urea) by evaporating a solution of these substances to dryness or by concentrating an alcoholic solution until crystallisation occurs; the product can be injected subcutaneously for the treatment of such ailments as hay fever and bronchial asthma, and unlike calcium chloride alone does not give rise to pain and inflammation.

—D. F. T.

Glycolyl-p-aminophenol ethers; Preparation of —.
 Farb- u. vorm. Meister, Lucius, u. Brünig. Ger. Pat. 306,938, Aug. 24, 1916.

GLYCOLYL-*p*-AMINOPHENOL ethers, in particular the methyl and ethyl ethers which are of use as antipyretics, can be obtained by heating together the corresponding ethers of *p*-aminophenol with an anhydride or ester of glycollic acid. Under the term "anhydride" are included not only glycolide and polyglycolide but also the insoluble crystalline product formed on heating glycollic acid at 200°—250° C., which regenerates glycollic acid on prolonged contact with water.—D. F. T.

Calcium halogenides and albumin; Manufacture of preparations of —. E. Ritsert, Pharm.-chem. Institut, Frankfurt. Ger. Pat. 306,978, Sep. 16, 1915.

THE preparations are obtained by bringing together approximately equal weights of calcium halogenide and albumin in presence of a small quantity of water. The calcium chloride compound if dried at a gentle heat retains its power of swelling on treatment with water, but by stronger heating becomes insoluble, and this property renders it suitable for use in the finishing, etc., of textiles.

Urea; Manufacture of —. C. Bosch, A. Mittasch, and C. Nereshheimer, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,274,503, Aug. 6, 1918. Date of appl., Apr. 16, 1915.

SEE Eng. Pat. 24,042 of 1914; this J., 1916, 71.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photo-chemical reactions in photography. F. Schanz. *Z. wiss. Phot.*, 1918, 17, 261–263.

THE author has previously shown that all organic substances are decomposed by light of the wavelength which they absorb; colourless transparent substances are decomposed by ultra-violet light, or, if they are stable to daylight, by radiation of still shorter wavelength ("outer" ultra-violet). It is now suggested that the light-sensitiveness of photographic materials is due chiefly to the organic carrying medium of the silver salt (albumin, gelatin, collodion) rather than to the silver salt itself. The absorption spectra of dialysed albumin, 10% gelatin solution, and collodion solution to ultra-violet and outer ultra-violet are given; with the two latter absorption is from about 350 μ upwards and with albumin from 300 μ . The spectra for potassium bromide and silver nitrate solutions are also given, the absorption being negligible. The author suggests also, in analogy with the increase in light-sensitiveness of albumins by dyeing, that in the colour-sensitising of photographic plates it is the relationship between the dye and the medium which is important.—B. V. S.

Spectral intensities; A method for the determination of — by photographic means. G. Holst and L. Hamburger. *Z. wiss. Phot.*, 1918, 17, 261–267.

IN front of the slit of a Hilger quartz-spectrograph is placed a revolving sector with an aperture increasing radially according to a logarithmic law. The relationship between the intensity of the spectral line and its length in the resulting photograph is given approximately by $\log I_2/I_1 = 1.5(I_2 - I_1)$, l being measured in cm. The accuracy of the method is about 10% with a range of intensity ratio of 1:20. The method has been used in quantitative determinations of the influence of various factors on the light emission of gases.—B. V. S.

Photometer liquids in tablet form. W. Haussmann. *Z. wiss. Phot.*, 1918, 17, 268.

FOR greater convenience in handling, although with some loss of sensitiveness, photometer liquids are mixed with a sterilised agar-agar suspension, the mixture being allowed to set in Petri dishes. Eder's solution (mercuric chloride-ammonium oxalate) gives a colourless jelly in which a white opaque precipitate is formed on exposure to light; Roussin's liquid (sodium nitroprusside-ferrous chloride) gives a brownish coloured jelly turning to a strong blue colour.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Mercury fulminate; Colour reaction of — with phenylhydrazine. A. Langhans. *Z. angew. Chem.*, 1918, 31, 161–163.

WHEN dry mercury fulminate (0.2 to 0.3 grm.) is treated with 0.5 to 1 c.c. of phenylhydrazine and allowed to stand, the powder becomes olive-green changing to grey, whilst the liquid becomes brown and then reddish-brown. When diluted, after a few hours, with alcohol, and treated with dilute sulphuric acid, the liquid gives a fine reddish-violet coloration. The reaction, which is very sensitive, takes place more rapidly on heating. It can be used for the detection of mercury fulminate in the presence of potassium chlorate, antimony sulphide,

glass, and adhesive substance as contained in detonator and percussion cap compositions. The reaction is also produced by hydrochloric or nitric acids though not so sharply. Alkalis change the colour to yellow and give a precipitate, whilst acids restore the original colour. A solution of mercury fulminate in sodium thiosulphate or in pyridine also gives the reaction. If, prior to the reaction, the phenylhydrazine is treated with methyl iodide an intense violet to bluish-violet coloration of the character of methyl violet is obtained. The dye-stuff can be extracted with chloroform, and its reactions indicate that it is pararosamine. (See also *J. Chem. Soc.*, Nov., 1918.)—C. A. M.

PATENTS.

Explosives; Ammonium perchlorate —. Aktiebolaget Carlit, Stockholm, Sweden. Eng. Pat. 112,417, Aug. 21, 1917. (Appl. No. 12,009 of 1917.) Under Int. Conv., Dec. 30, 1916.

FROM 0.005 to 1% of a chlorate other than ammonium chlorate is added to or left in ammonium perchlorate, to render ammonium perchlorate explosives more sensitive to shocks and to increase the velocity of explosion.—T. St.

Separators; Centrifugal — [for nitrocellulose]. F. Matousek, Gary, Ind., U.S.A. Eng. Pat. 118,262, June 8, 1918. (Appl. No. 9444 of 1918.)

THE material to be separated, e.g., a mixture of nitrocellulose and nitrating acid, is fed from the rotating hopper, 20, through the corrugated outlet, 22, which can be closed more or less by the corru-

gated cone, 26, into the bowl, 16, which is provided with a perforated spiral corrugation, 19. The liquid is discharged through the perforations into the inner casing, 2, and the solid portion is discharged over the lip of the bowl, 16, into the annular space between the casings, 1 and 2. Means are provided for flooding or flushing out both the feed hopper and the bowl with water.—W. H. C.

Nitrated product and process of making same.
E. A. Barnes, Grant, Cal. U.S. Pat. 1,273,568,
July 23, 1918. Date of appl., Oct. 11, 1915.

REFINED petroleum distillates containing a preponderance of saturated hydrocarbons and a smaller proportion of benzenoid hydrocarbons, are treated at a low temperature with a mild nitrating agent consisting of nitric acid, sulphuric acid, and water, whereby the benzenoid hydrocarbons are converted mainly into their mono-nitro-derivatives. These are separated, and by treatment with a stronger nitrating agent at a higher temperature are converted into polynitro-derivatives.—T. St.

Edge runners, pan and like grinding mills. Eng.
Pat. 118,465. Sec I.

XXIII.—ANALYSIS.

Ultra-filter; New form of —. Some of its uses in biological and synthetic organic chemistry. P. A. Kober. J. Amer. Chem. Soc., 1918, 40, 1226—1230.

QUANTITATIVE dialysis has been made possible by the discovery that all semipermeable membranes pervaporate (see this J., 1917, 1038). An apparatus for ultra-filtration by dialysis is figured and described. It consists essentially of a dialyser connected by a siphon to a pervaporator, and its action depends on pervaporating both the dialysate and the diffusate solutions during dialysis. Solutions containing humic material or highly coloured by-products which cannot be removed by charcoal are rapidly and completely clarified by ultra-filtration.—C. S.

[Electrical] conductivity; New method for the determination of —. E. Newbery. Chem. Soc. Trans., 1918, 113, 701—707.

ALTHOUGH the method introduced by Kohlrausch is almost universally used for the determination of the electrical conductivity of solutions, a critical examination shows that it is based on a number of assumptions which have not so far been subjected to the test of experiment. A new method is described in which continuous current is used and in which polarisation effects are completely eliminated. It is analogous to a method commonly used for measuring the resistance of a metallic conductor by determining the fall of potential along it during the passage of a known current. The non-polarisable electrodes employed in the method vary somewhat according to the nature of the solution under examination. The following values were obtained for the specific conductivity at 25° C.: N/1 KCl 0.1124, N/1 AgNO₃ 0.07796, N/1 H₂SO₄ 0.2137. For the KCl solution the value is 0.3% greater, and for the H₂SO₄ solution 3.6% less, than the value recorded by Kohlrausch.—H. M. D.

Phosphoric acid; Determination of — as magnesium pyrophosphate. IV. D. Balareff. Z. anorg. Chem., 1918, 104, 53—56.

EXPERIMENTS have been made on the precipitation of magnesium ammonium phosphate by Schmitz' method, which consists in adding ammonia to a hot acid solution of the phosphate-magnesia mixture. Whether precipitation takes place immediately or only on cooling depends upon the dilution and the quantity of ammonia added, but such changes in conditions do not affect the final results, nor do wide variations in the quantity of ammonium chloride present. The precipitate, however, is not pure, but loses some phosphoric acid on ignition, the residue being relatively rich in magnesium and

poor in phosphoric acid, but the errors involved approximately compensate one another. It is not advisable to redissolve and reprecipitate after ignition of the first precipitate, as is sometimes recommended. In presence of sulphate ions the results tend to be high and in presence of acetate ions, low, whilst nitrate ions are without influence. (See also J. Chem. Soc., Nov., 1918.)—E. H. R.

Boric acid; Use of manna in the determination of —. L. E. Hes. Analyst, 1918, 43, 323.

A FRESHLY prepared neutralised solution of manna may be used in place of glycerol in the determination of boric acid. As a rule a solution containing about 5 grms. of manna, which should be free from waxy portions, is equivalent to about 25 c.c. of 80% glycerol.—C. A. M.

Alkylamines; Method for the separation and quantitative estimation of the lower — in the presence of ammonia. F. C. Weber and J. B. Wilson. J. Biol. Chem., 1918, 35, 385—410.

THE new method depends upon the reaction of ammonia with mercuric oxide in alkaline solution and upon the reactions of the three classes of amines with nitrous acid and the subsequent reduction of the diaminonitrosoamine formed to diamine with nascent hydrogen. The ammonia is precipitated with mercuric oxide (François, this J., 1917, 432, 721) and then the total amines are determined by distillation into standard acid. After the titration, the distillate is evaporated with concentrated sulphuric acid, diluted, and an aliquot part treated with nitrous acid for 30 mins. in Van Slyke's apparatus, the amount of nitrogen evolved being a measure of the monoamines. The remainder of the solution is treated with nitrous acid for 3—1 hour, then with a quantity of sodium hydroxide insufficient to neutralise it, allowed to stand for several hours, made alkaline, and distilled, the trialkylamine being absorbed in standard acid. The dialkylamine is determined by difference, or the distillate is treated with hydrochloric acid and zinc to reduce the dialkylaminonitrosoamine, and the diamine then determined by distillation. The method appears to give accurate results and may be applied to the analysis of fish products, putrid flesh, bad sausages, biological fluids, etc. (See further J. Chem. Soc., 1918, ii., 377.)—H. W. B.

Adamkiewicz reaction [of proteins] and the transformation of glyoxylic acid into formaldehyde. E. Voisenet. Bull. Soc. Chim., 1918, 23, 361—369.

AS OPPOSED to the view of Hopkins and Cole (Roy. Soc. Proc., 1901, 68, 21) the author considers that this colour reaction (violet coloration on adding concentrated sulphuric acid to a solution of a protein in glacial acetic acid) is due to the presence of formaldehyde and not of glyoxylic acid. Acetic acid always contains traces of formaldehyde formed by oxidation. Glyoxylic acid also is readily decomposed with formation of formaldehyde. The method recommended for carrying out the test is to add to the protein sulphuric acid, followed successively by 1 drop of 0.4% formaldehyde and 1 drop of 1% sodium nitrite solution.—W. G.

Device for determining the dropping point (melting point) of fats, waxes, paraffin wax, etc., and especially bitumens. Dupré. See IIa.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Barbet et fils et Cie. Recovery of tar from pyroligneous liquids. 16,457. Oct. 9. (Fr., Oct. 11, 1917.)
Barbet et fils et Cie. Treatment of pyroligneous liquids derived from carbonisation of wood. 16,599. Oct. 11. (Fr., Oct. 11, 1917.)
Soc. d'Eclairage, Chauffage, et Force Motrice. Production of high-percentage carbazole. 16,291. Oct. 7. (Fr., Dec. 4, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

9713 (1917). Alexander. *See* II.
13,955 (1917). Mandl. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Halvorsen and Hørbye. Manufacture of sulphur dyes. 16,381. Oct. 8.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Johnston and Sutherland. Method of degumming and cleansing stalk fibres. 16,181. Oct. 5.
Langwell. Fermentation of cellulose. 15,942. Oct. 1.
MacDonald. Solutions of cellulose esters. 16,017. Oct. 2.
MacDonald. Manufacture of vulcanised fibre, and apparatus for washing fibrous and like substances to recover chemicals. 16,315. Oct. 7.
Privett, and Thames Paper Co. Apparatus for drying paper, paper board, etc. 16,219. Oct. 5.
Spicer, and Spicer and Sons. Filter paper, etc. 16,216. Oct. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

14,290 (1917). Wegmann & Co. Treatment of fabric pieces. (111,466.) Oct. 16.
832 (1918). Aitken. Paper-making machines. (119,594.) Oct. 16.
3336 (1918). Dreyfus. Manufacture of unflammable celluloid. (114,304.) Oct. 16.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Crosland, Dixon, and Hawley. Machines for mercerising, dyeing, etc., hose, etc. 16,472 and 16,473. Oct. 10.
Gott. Dyeing and bleaching textile materials. 16,430. Oct. 9.
Macintyre. Machine for dyeing, bleaching, washing, etc., yarn in hank. 16,149. Oct. 4.
Tütsch. Bleaching boiler plant. 15,965. Oct. 1. (Ger., Oct. 2, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

14,391 (1917). Calico Printers' Assoc., and Ashton. Printing of textile fabrics. (119,298.) Oct. 9.
681 (1918). Dudley. Dyeing machine. (112,630.) Oct. 9.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Barbet et fils et Cie. 16,599. *See* III.
Bradbury. Manufacture of salt. 16,573. Oct. 11.
Busvold. Manufacture of bismuth compounds and metallic bismuth. 15,862. Sep. 30. (Norway, Oct. 3, 1917.)
Morris. Production of antimonious oxide. 16,333. Oct. 8.
Morris. 16,334 and 16,335. *See* XIII.
Tyron. Manufacture of manganates and permanganates. 16,446. Oct. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

12,058 (1917). Dutt and Dutt. Manufacture of sodium and aluminium hypochlorites. (119,261.) Oct. 9.

12,363 (1917). Ashcroft. Extraction of potash or potassium salts from potash-bearing materials. (119,492.) Oct. 16.

13,975 (1917). Grossmann. Utilisation of ultre cake. (119,290.) Oct. 9.

549 (1918). Thorsell and Lunden. Manufacture of hydrogen. (119,591.) Oct. 16.

VIII.—GLASS; CERAMICS.

APPLICATION.

McCoy. Apparatus for production of sheet glass. 16,591. Oct. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

14,293 (1917). Mond. Glass chemical ware. (119,297.) Oct. 9.

2667 (1918). Dupont. *See X.*

12,788 (1918). Soc. Anon. des Prod. Réfractaires de l'Ouest. Manufacture of silica bricks. (118,116.) Oct. 9.

IX.—BUILDING MATERIALS.

APPLICATION.

Alexander. Manufacture of bricks, building and paving blocks, etc. 16,619. Oct. 11.

COMPLETE SPECIFICATION ACCEPTED.

2958 (1918). Borch. Manufacture of Portland cement. (113,785.) Oct. 9.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Annable, and Nickel Concentration, Ltd. Extraction of nickel from silicate ores. 16,539. Oct. 10.

Basset. Manufacture of iron and steel from ore. 16,034. Oct. 2. (Fr., Oct. 3, 1917.)

British Thomson-Houston Co. (General Electric Co.). Coating metals. 15,944. Oct. 1.

Busvold. 15,862. *See VII.*

Gordon, and Spear and Jackson. Manufacture of steel for valves of internal-combustion engines. 16,237. Oct. 7.

Minerals Separation, Ltd., and Wood. Concentration of ores. 16,208. Oct. 5.

Ness. Electroplating and electro-cleaning apparatus. 16,142. Oct. 4.

Parkes and Thomas. Concentration and refining of metallic residues. 15,985. Oct. 2.

Reece. Treatment of ore concentrates, fines, slimes, dust, etc. 16,325. Oct. 7. (Australia, Sep. 18, 1917.)

Schneider et Cie. Ascertaining hardness of metal articles. 16,390. Oct. 8. (Fr., Nov. 7, 1917.)

Stein et Cie. Annealing furnaces. 16,517. Oct. 10. (Fr., Aug. 24.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,273 (1917). Hodson. Metallic alloys. (119,486.) Oct. 16.

1710 (1918). Stabilimentl Biak Ing. A. Pouchain. Manufacture of alloys containing nickel and zinc. (113,272.) Oct. 16.

2667 (1918). Dupont. Enamelling metal articles, and furnace therefor. (114,618.) Oct. 16.

5113 (1918). Gravell. Cleaning metals. (119,618.) Oct. 16.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Morgan Crucible Co., and Speirs. Current-regulating devices for electrically heated crucible retorts, muffles, etc. 16,673. Oct. 12.

Ness. 16,142. *See X.*

COMPLETE SPECIFICATIONS ACCEPTED.

14,309 (1917). Fuller Accumulator Co., and Wood. Electric storage batteries or accumulators. (119,530.) Oct. 16.

14,833 (1917). Kievits, and Kynoch, Ltd. Electric furnaces of the heated-coil type. (119,302.) Oct. 9.

5866 (1918). Aktieselskab Arendal Smelteverk. Electrode-holders for electric furnaces. (114,841.) Oct. 16.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Engel. 16,439. *See II.*

Helmes. 16,170. *See II.*

COMPLETE SPECIFICATION ACCEPTED.

17,577 (1917). Greenhalgh. Extraction of oil from vegetable fruits. (111,676.) Oct. 16.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Kelly. Flexible waterproof antiseptic and anti-fouling composition. 15,940. Oct. 1.

MacLean. Washable distempers or water paints. 16,317 and 16,318. Oct. 8.

Morris. Manufacture of antimony colours. 16,334 and 16,335. Oct. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

10,705 and 10,706 (1917). Wade (Redmanol Chemical Products Co.). Manufacture of phenolic condensation products. (119,252 and 119,253.) Oct. 9.

227 (1918). Breakell. *See I.*

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Marshall and Walworth. Grinding vulcanised rubber. 16,565. Oct. 11.

Marshall. 16,566. *See XV.*

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Carmichael. Unhairing of hides and skins. 16,188. Oct. 5.

Doran. Manufacture of leather. 16,175. Oct. 4. (Norway, May 11.)

Goodwin and Pratt. Treatment of hides, skins, etc. 15,870 and 15,871. Sep. 30.

Hewitt and Kay. Hide-tanning by compressed air. 16,194. Oct. 5.

Marshall. Manufacture of substitutes for leather and rubber goods. 16,566. Oct. 11.

Trenaman. Composition for waterproofing leather articles. 15,969. Oct. 1. (U.S., Dec. 20, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

14,982 (1917). Ward. Substitute for leather. (119,304.) Oct. 9.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

August. Treatment of soil. 16,416. Oct. 9.

Fitzgerald. Manufacture of nitrogenous manures, etc. 16,220. Oct. 5.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Alexander. Manufacture of edible syrup from sugar beetroot. 16,607. Oct. 11.

Marks (Ideal Coated Paper Co.). Adhesive. 16,954. Oct. 11.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Langwell. 15,942. *See V.*

COMPLETE SPECIFICATION ACCEPTED.

16,829 (1917). Kazman. Production of alcohol. (119,333.) Oct. 9.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Beer. Process for recovering and making cheese of food matters in whey. 16,131. Oct. 4.

Brodrick. Manufacture of drinks. 16,642. Oct. 12.

Candy. Filters for purifying liquids. 16,023. Oct. 2.

James, and Heenan and Froude. Refuse destructors. 16,400. Oct. 9.

Nieuwhof, Surie, & Co., and Surie. Manufacture of milk powder. 16,658. Oct. 12.

Vuyksteke. Water, etc., filters. 16,020. Oct. 2.

Weeks. Germicide solution. 16,606. Oct. 11.

Westaway. Means for preserving milk, cream, fish, etc. 16,310. Oct. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

10,455 (1917). Lecomte. Sterilising milk and similar liquids. (116,490.) Oct. 9.

10,414 (1918). Turney. Process of making a new food product of milk. (119,430.) Oct. 9.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Imray (Soc. Chem. Ind. in Basle). Manufacture of esters of N-monoarylsulphomonoalkylamido-oxyaryl compounds and arylsulpho esters of amido-oxyaryl compounds. 16,379. Oct. 8.

Morris and Reeve. Medicinal preparation. 16,293. Oct. 7.

Rockefeller Institute for Medical Research. Arsenical compounds. 16,092—16,096. Oct. 3. (U.S., Oct. 3, 1917.)

COMPLETE SPECIFICATIONS ACCEPTED.

8259 (1917). Marks (Du Pont de Nemours and Co.). Production of alcohols. (119,249.) Oct. 9.

8862 (1917). Boake and Durrans. Production of dimethyl sulphate. (119,250.) Oct. 9.

13,964 (1917). Imray (Soc. Chem. Ind. in Basle). manufacture of a preparation from *Secale cornutum*. (119,287.) Oct. 9.

14,150 and 14,151 (1917). Selden Co., and Gibbs. Process for oxidising aromatic hydrocarbons and the lower oxidation products thereof. (119,517 and 119,518.) Oct. 16.

8026 (1918). Utheim. Manufacture of chloroform. (116,094.) Oct. 16.

XXIII.—ANALYSIS.

COMPLETE SPECIFICATIONS ACCEPTED.

14,352 (1917). Parsons and Law. Means for detecting or measuring moisture. (119,533.) Oct. 16.

18,331 (1917). Towers and Harger. Burettes and the like. (119,580.) Oct. 16.

I.—GENERAL ; PLANT ; MACHINERY.

PATENTS.

Ball-mill. C. Candlot, Paris. Eng. Pat. 115,223, Dec. 13, 1917. (Appl. No. 18,459 of 1917.) Under Int. Conv., Apr. 25, 1917.

A BALL-MILL is provided with two series of oppositely directed helicoidal ribs which serve to heap up the material being ground towards the middle of the cylinder. A conical screen is provided at the outlet end.—W. H. C.

Separation of solids from liquids; Apparatus for the continuous —. A. Bontemps and G. N. Vis, Paris. Eng. Pat. 118,855, Mar. 16, 1917. (Appl. No. 3866 of 1917.)

A HOLLOW cone having a raised screw thread on its outer surface is rotated point downwards within another perforated cone surrounded by an outer casing. The material to be separated is forced into the space between the cones from below. The liquid passes through the perforated cone into the outer casing and the solid matter is carried upwards by the screw thread and is discharged at the upper end into a suitable receptacle. Steam or other treating agent may be passed into the interior of the hollow cone, the distance of which from the outer cone may be adjusted by a screw. —W. H. C.

Lagging and process for preparing the same. E. Foster, St. Heliers Bay, New Zealand. Eng. Pat. 118,871, Aug. 9, 1917. (Appl. No. 11,451 of 1917.)

SODIUM silicate, 100 parts, is heated, and mixed with diatomaceous earth 40–60 parts, and lime 2–10 parts. The mass is placed in heated moulds and heated in a furnace to 400° F. (205° C.) or upwards. The product is porous and easily detached from the mould.—W. F. F.

Spraying liquids; Apparatus for —. I. Hechenbleikner, Assignor to Chemical Construction Co., Charlotte, N.C. U.S. Pat. 1,273,856, July 30, 1918. Date of appl., Feb. 14, 1918.

A DEVICE intended more especially for spraying acids into concentrating apparatus comprises a tube, 11, provided with spraying apertures, 21, and also with a central overflow tube, 24. The acid contained in the receptacle, 16, overflows over the upper edge of 14, and through openings into the tube, 11, and thence out through the spraying apertures, 21. Should these become clogged, the acid rises in the tube, and overflows into the inner tube, 24. This can be observed through the transparent cover, 25, and in such case the cover is removed and the tube, 24, raised, whereupon a rapid flow of acid down 11 and out through the opening, 23, clears the apertures, 21.

Absorbing heat; Apparatus for —. [Vacuum evaporator.] H. H. Dow and T. Griswold, jun., Assignors to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,275,231, Aug. 13, 1918. Date of appl., June 7, 1916.

A VACUUM pan has a number of approximately vertical upflow tubes for the liquid to be evaporated

and a downflow tube of considerably larger cross-section situated nearer the outlet for the heating medium than to the inlet. The upflow tubes are distributed uniformly throughout the chamber, except adjacent to the inlet and outlet for the heating medium, where two wedge-shaped spaces are left, the larger end of each of these spaces facing respectively towards the inlet and outlet for the heating medium.—W. H. C.

Dust-collector. W. J. P. Cloakey, Brantford, Ont., Canada. U.S. Pat. 1,275,663, Aug. 13, 1918. Date of appl., Jan. 5, 1918.

A SCREEN drum having radial longitudinal screen partitions extending part of the way from the periphery towards the axis is rotated about a stationary cylinder and dips into water in a tank. The cylinder has a number of external arc-shaped wings extending lengthwise, the arcs being of greater length than the distance between any two of the partitions. A port is provided in the side of the cylinder between the wings, and inside the cylinder but out of alignment with the port is a rotary beater into which water is conducted near its axis. The dust-laden air is led into the beater and passes thence into the cylinder.—W. H. C.

Air-cleaner. A. C. Bennett, Minneapolis, Minn. U.S. Pat. 1,276,016, Aug. 20, 1918. Date of appl., Feb. 28, 1917.

A VERTICAL cylindrical casing is provided on its inner wall with a helical conduit terminating near the lower end. The air to be treated is discharged through this conduit so that it passes into the lower part of the casing with a whirling motion. A conical baffle-plate is arranged with its apex at the level of the lower end of the conduit, and its base spaced from the lower wall of the casing. Separated solid material falls between the cone and the wall of the casing and is collected in a well in the bottom of the casing.—W. F. F.

Vacuum dehydrator; Continuous —. C. Biesel, El Paso, Tex. U.S. Pat. 1,276,163, Aug. 20, 1918. Date of appl., Jan. 11, 1917.

A ROTARY hollow drum is fitted with a peripheral suction chamber and with an outer filtering medium, and the filter-cake is removed from the drum face by a number of wires supported on a frame and arranged tangentially to the filtering surface. The filtered liquid is removed from the suction chamber without interrupting the vacuum. —C. A. K.

Heating boilers by waste gases; Means for —. L. S. Schmidt, Pittsburgh, Pa. U.S. Pat. 1,276,421, Aug. 20, 1918. Date of appl., Feb. 4, 1916.

THE outlet of a waste gas flue is arranged between the inlet of a boiler flue and the inlet of a flue leading to the stack. The ports are adjacent to one another and in the same horizontal plane. A valve member with a curved passage is arranged over the ports so that the central waste gas port may be put in communication with either of the side ports by moving the valve member, while at the same time the port not in use is automatically covered by a flap. All the ports are provided with water seals on their horizontal surfaces out of the path of the waste gases. —W. F. F.

Dry-kiln. H. D. Tiemann, Madison, Wis., and N. de W. Betts, Linwood, Utah, Assignors to the Government and people of the United States. U.S. Pat. 1,276,451, Aug. 20, 1918. Date of appl., Apr. 6, 1917. (Dedicated to the public.)

A DRYING chamber is provided with a flue adjacent to it for heating the circulating medium, and steam is discharged at a point adjacent to the heating device. The steam passes rapidly through the heating flue and induces a large circulation through the drying chamber, and at the same time becomes superheated.—W. F. F.

Suspended particles; Process of freeing liquids from —. V. M. Goldschmidt, Assignor to Titan Co. A/S, of Norway, Christiania, Norway. U.S. Pat. 1,276,644, Aug. 20, 1918. Date of appl., Jan. 31, 1918.

A LIQUID containing suspended solid particles of electropositive colloidal silicon hydroxide is mixed with a ferric salt and treated with hydrogen sulphide. Electronegative colloidal sulphur is precipitated, the particles of which envelop and coagulate the electropositive particles, which may then be removed.—W. F. F.

Dephlegmator and rectifying column. D. Pyzel, San Francisco, Cal. U.S. Pat. 1,276,690, Aug. 20, 1918. Date of appl., Oct. 10, 1916.

A VERTICAL cylindrical shell is provided with a vapour inlet at the bottom and outlet at the top. A cooling coil, fixed within the shell near the top, serves to condense the heavier products, which fall back into a rectifying column below and are there revaporised by heated vapours which circulate around the column. A heating coil in the bottom of the shell serves to revaporise any liquid condensing in the rectifying column.—W. H. C.

Separating liquids from solids; Process of and apparatus for —. A. M. Nicholas, Torrington, N.S.W. Eng. Pats. 110,349 and 110,350, Sep. 11, 1917. (Appl. Nos. 13,021 and 13,022 of 1917.) Under Int. Conv., Oct. 13, 1916.

SEE U.S. Pats. 1,268,273 and 1,268,274 of 1918; this J., 1918, 497 A.

Cooling and otherwise treating gases with liquids; Apparatus for —. A. W. Mathys, London. U.S. Pat. 1,275,583, Aug. 13, 1918. Date of appl., Nov. 8, 1916.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Effects of moisture on spontaneous heating of stored —. S. H. Katz and H. C. Porter. U.S. Bureau of Mines, Tech. Paper 172, 1917. 25 pages.

THE relative rates of absorption of oxygen by dry and moist samples of two bituminous coals were determined. The dry samples were prepared by desiccation over phosphoric anhydride *in vacuo*

or in nitrogen; the moist samples were simply air-dried. 100 grms. of the coal (through 80-mesh, or 100-mesh sieve) was exposed to about $4\frac{1}{2}$ litres of air dried by phosphoric anhydride or to moist air, in a closed vessel connected to a manometer and maintained at 25° C. in a water-bath for 100 days. Computations were made from the changes in pressure and analyses of the gaseous contents of the vessels. The results are tabulated and shown graphically. The volume of oxygen absorbed ranged between 279 c.c. and 521 c.c. in the different experiments. Carbon dioxide (10 c.c. to 43 c.c.) and a trace of carbon monoxide (4 c.c. to 10 c.c.) were produced, but the bulk of the absorbed oxygen remained in the coal substance. Dryness favoured the rate of oxidation for one coal but retarded it for the other. The authors conclude that as both coal and air contain moisture under natural conditions of coal storage, water, other than the excess that actually wets the coal, does not play any important part in increasing the danger of spontaneous heating. On the other hand, excess water, held by capillary action in the small coal of a storage pile, probably stifles ventilation of the pile, and consequently the heat of slow oxidation gradually accumulates. To stop this action, the segregation of small coal, when building a storage pile, must be prevented.—T. F. E. R.

Blue water-gas practice in conjunction with benzol recovery. E. F. Keable. Eastern Counties Gas Assoc., Oct. 3, 1918. Gas J., 1918, 144, 77—79.

THE author describes results obtained from a "K and A (Smith's modification) plant." The producer consists of a steel shell containing two generators, each of which is surrounded in the upper portion by a regenerator. During the "blow" ($\frac{1}{2}$ to 1 min.) the blast enters the bottom of both generators, passes through the fuel and meets secondary air on entering the regenerators. The "run" occupies 5 mins. and the steam passes down one regenerator (becoming superheated) into the respective generator, whence it proceeds under a midfeather into the second generator and then passes up through the column of cool coke feeding the latter generator, to the gas outlet. When carburetting, the oil is simultaneously cracked in the second regenerator and the oil-gas becomes mixed with the blue water-gas at the point of entry into the cool coke column. After the next "blow" the above operations are repeated in the reverse direction. With this plant, clinkering troubles are reduced, heat is given up by the blue water-gas to the cool coke, the gas leaves the plant freed from dust, and the content of carbon dioxide is low. The addition of 20—32% of blue water-gas (sp. gr. 0.6, cal. value 331 B.Th.U. gross per cub. ft.) to coal-gas of 600 B.Th.U. gross per cub. ft. produced a mixture which averaged 520 B.Th.U. gross, and which gave no trouble in use. 298 lb. of coke was used per 1000 cub. ft. of blue water-gas. The simultaneous working of the blue water-gas plant and the benzol-recovery plant necessitated very carefully balanced conditions to maintain a uniform quality of gas. 1.79 galls. of crude benzol was recovered per ton of coal carbonised.

—T. F. E. R.

Gases; Differential pressure method for the determination of [benzene] vapours in —. H. S. and M. D. Davis. J. Ind. Eng. Chem., 1918, 10, 709—712.

TWO flasks are connected by a manometer; one is filled with air and the other with air containing benzene in quantity less than will saturate the air. A small bulb of benzene is then broken in each flask. In the flask containing air, the benzene will produce the total saturation pressure whilst in the

other flask it will only add the amount of pressure necessary to bring the pressure up to saturation. The manometer will, therefore, indicate a difference in pressure between the two flasks equal to the pressure of the benzene vapour in the original air-benzene mixture. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Gases; Application of the differential pressure method to the determination of benzene and total light oils in —. H. S. and M. D. Davis and D. G. MacGregor. J. Ind. Eng. Chem., 1918, 10, 712–718.

The method described in the preceding abstract may be used for the determination of total benzene, toluene, and xylene in gases. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Gases; Absorption of light oils from —. H. S. and M. D. Davis. J. Ind. Eng. Chem., 1918, 10, 718–725.

The flow of oil necessary to remove completely benzene from a gas may be calculated, since the vapour pressure of benzene in oil is governed by Henry's law for the solubility of gases in liquids and by Von Raoult's law for the constancy of the fractional lowering of the vapour pressure from a solution over variations in temperature. A method, based on the determination of the molecular weight of an oil dissolved in benzene and calculation of the fractional lowering of the vapour pressure of benzene by the addition of 99% of the oil, is suggested for standardising oils used for absorbing vapours from gases. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Benzol; Production of — from Italian crude petroleum. A. G. Rodano. Annali Chim. Appl., 1918, 10, 23–26.

A sample of crude petroleum from the province of Pavia had the following characters:—Sp. gr. at 15° C., 0.9132; viscosity (Engler) at 20° C., 1.77; flash-point, 80° C.; calorific power, 10,600 cal.; and total sulphur, 0.22%. It began to distil at 180° C., and on distillation 160 c.c. yielded the following fractions:—From 180° to 250° C., 26 c.c.; 250° to 280° C., 26 c.c.; 280° to 310° C., 18 c.c.; 310° to 360° C., 18 c.c.; 360° to 370° C., 6 c.c.; and residue, 6 c.c. The oil was only fit for heating purposes. When "cracked" (see this J., 1917, 1091), 100 c.c. of the crude oil yielded 25 litres of combustible gas, 9 c.c. of oils distilling up to 122° C.; 5 c.c. between 122° and 170° C., and 16 c.c. of residual tar completely soluble in aniline. The oil distilling up to 122° C. consisted of a mixture of benzol and toluol in which the latter predominated. On "cracking" the fractions (52 c.c.) of the original oil distilling up to 280° C. they yielded 94% of benzol and toluol, equivalent to 48% on the original petroleum, or only about half of that produced by "cracking" the original petroleum. On the other hand, in the second case the residue from the original oil after distilling off the lighter portion could be used as a lubricant.—C. A. M.

Bitumens; Valuation of natural and artificial — [for insulating cables] by means of a new "bitumen tester." Dupré. Chem.-Zeit., 1918, 42, 445–446. (See this J., 1918, 615 A.)

Of the few varieties of bitumen having the requisite elasticity and hardness for use as insulators for electric cables elastolite is the best known. Since, owing to the war, this is no longer procurable in Germany, attempts have been made to prepare substitutes ("insulation tar," "insulation masses," etc.) by incorporating up to 40% or more of kaolin,

chalk, etc., with natural or artificial bitumens having a dropping-point (melting-point) of about 40°–60° C. Such addition, however, only retards the flowing of the mass at higher temperatures, and cables insulated with such materials lose their shape as certainly, though not so soon, as if the unfilled bitumen were used. The improvement of ordinary bitumens, asphalts, pitches, etc., so as to raise the dropping-point, while retaining their elasticity and ductility, can only be effected by a deep-seated chemical alteration of the bitumens. For example, if the mineral matter is made to combine with the bitumen as in Schön and Co.'s patent process (not yet published), the dropping-point of a bitumen may be raised from, e.g., 41° C. to 115° C. The so-called "original Trinidad asphalt (puré)" has a dropping-point of about 105° to 115° C., and contains about 30 to 40% of mineral substances. But, owing to their reduced elasticity, these products cannot be used as the permanent basic material for cable masses, and are, at best, only suitable for admixture with elastic bitumens of lower dropping-point. The second method of raising the dropping-point is by chemical treatment of the bitumen without the addition of mineral matter. Only first-grade bitumens are suitable for cable masses, viz., those with the requisite elasticity, ductility, and adhesiveness, and a dropping-point of at least 75° to 95° C., whilst if the "semi-bitumens," including natural or artificial tars, asphalts, petroleum pitch, etc., with a dropping-point of 40° to 60° C. be used, the cable mass will lose its form when exposed to an external temperature of 20° to 30° C.—C. A. M.

Analysing spent oxide. Wentzel. See VII.

PATENTS.

Peat; Treatment of — for fuel and apparatus therefor. K. E. Edgeworth, British Expeditionary Force, France. Eng. Pat. 118,903, Sep. 24, 1917. (Appl. No. 13,714 of 1917.)

Wet peat, which has previously been heated to 150° C. in a closed vessel, is forced into a filtering vessel at a pressure of 600 lb. per sq. in. and a temperature of 200° C. The filtering elements are conical, with thick walls, and are formed of unglazed porcelain or earthenware. These elements are mounted on a vertical perforated outlet pipe in the centre of the vessel, and their outer edges are spaced from the walls of the vessel, so that the elements are entirely surrounded by the wet peat. The water percolates through the walls of the cones into the discharge pipe. To discharge the peat, the inlet pipe is closed, and the filtration allowed to continue till the temperature falls to 105°–130° C. An outlet passage is then opened and the sudden decrease in pressure and consequent generation of steam disintegrates and forces out the peat. Modified forms of filtering elements are also described.—W. F. F.

Coal; Process of treating —. C. H. Smith, Short Hills, N.J., Assignor to International Coal Products Corporation, Richmond, Va. U.S. Pats. (A) 1,276,427 and (B) 1,276,428, Aug. 20, 1918. Dates of appl., Jan. 20 and 31, 1916.

(A) Coal is heated until it reaches the plastic state and is then mixed with combustible material such as coke for the purpose of absorbing gases and condensed products entrained in the plastic residue. The mass is then moulded into briquettes by pressure applied at various stages of cooling. (B) The coal is heated until plastic, removed from the retort, subjected to a partial vacuum to remove gases entrained in the mass, and then moulded into briquettes.—T. F. E. R.

Briquette and method of making the same. C. H. Smith, Short Hills, N.J., Assignor to International Coal Products Corporation, Richmond, Va. U.S. Pat. 1,276,429, Aug. 20, 1918. Date of appl., Nov. 15, 1916.

BRIQUETTES are made (1) by carbonising a mixture of a binder and partially carbonised coal, (2) by mixing coal, coke, or partially carbonised coals, too low in volatile matter for direct briquetting, with a hydrocarbon binder so as to obtain a mixture containing 11–17% of volatile matter, then briquetting, and carbonising at 1400°–2000° F. (760°–1090° C.), (3) by partially distilling coal at a low temperature, compressing the residue into moulds and then distilling at a higher temperature to produce a strong coherent briquette.—T. F. E. R.

Pitch; Burners for —. South Metropolitan Gas Co., and A. Kirby, London. Eng. Pat. 118,890, Sep. 14, 1917. (Appl. No. 13,205 of 1917.)

MELTED pitch after passing through a steam jacketed chamber issues from an orifice into an injector jet and is then atomised, and passes into the furnace where it is burned. The outlet of pitch through the burner orifice is regulated by a rotating disc provided with holes of different sizes. Efficient atomisation is assured by employing a steam jet in close proximity to the injector jet.

—T. F. E. R.

[Coke ovens;] Plant for utilising waste heat [from —]. R. D. Martin, El Reno, Okla. U.S. Pat. 1,275,962, Aug. 13, 1918. Date of appl., June 20, 1917.

A NUMBER of coke ovens are arranged in two parallel rows, with a main flue extending between the rows midway of their height, and in contact with the sides of the ovens. Each oven has a tubular neck closed by a cover, and a flue leads from each neck over the curved top of the oven into the main flue. A steam generator is mounted on the setting of the ovens and a furnace and flue are arranged immediately below it and between the outer portions of two of the ovens. The furnace flue is connected to the main flue by a horizontal flue passing between the two ovens.

—W. F. F.

Power production; Use of solid fuel for large scale —. Merz and McLellan, and A. C. Michie, Newcastle-on-Tyne, and E. G. Weeks, Monk-seaton, Northumberland. Eng. Pat. 118,777, July 6, 1917. (Appl. No. 717 of 1918.)

COAL is fed continuously into a low-temperature vertical retort, A, and the coke is discharged at the bottom into a producer, B. Air and steam are

supplied by pipes, B¹, B², to the producer, and the resulting gas is passed through a stripping plant, C, to an internal combustion engine, D. The burnt gas passes through a steam generator, E, provided with an economiser, E¹, and thence to the exhaust. The steam passes partly through a superheater, F, heated by a portion of the stripped gas supplied by the pipe, C², to the retort, A, and partly through the pipe, B², to the producer. Distillation gases from the retort pass by the pipe, G, to the cooler, H, supplied with water from the engine jackets, D, by the pipe, K¹. The heated water then passes by the pipe, K², to the steam generator, E. The gas leaving the cooler passes to a second cooler, J, cooled by cold water, and the condensed products from the two coolers collect in the vessel, M. The residual gas passes by the pipe, J¹, to the stripping apparatus, C, and thence to the engine, D.

—W. F. F.

[Gas] retort settings; Horizontal and inclined —. R. Dempster and Sons, Ltd., and R. M. Brooke, Elland, Yorks. Eng. Pat. 118,804, Mar. 14, 1918. (Appl. No. 4504 of 1918.)

IN a setting for horizontal or inclined retorts having a step grate, producer gas is withdrawn from the furnace at the back, and passes through a flue extending through the setting from front to back to a number of horse-shoe burners along both sides of the combustion chambers. Secondary air is supplied through annular concentric passages in the burners.—W. F. F.

Gas producers and the like; Open hearth —. The Dowson and Mason Gas Plant Co., Ltd., and F. A. Webb, Manchester. Eng. Pat. 118,689, Sep. 12, 1917. (Appl. No. 13,049 of 1917.)

A VERTICAL producer is provided with a grate formed of a metal plate in the shape of an inverted frustum of a cone. The outer edge of the plate is attached to the bottom of the producer wall by a fixed metal ring provided with air holes. The ring is surrounded by a metal sleeve having corresponding holes, which can be rotated so as to vary the passages for secondary air to the producer. Below the conical grate and spaced from it, is a horizontal fire-bar grate of larger diameter. The bars are hollow and of triangular section with their bases at the top. They are threaded on to a steam pipe at one end, and their sloping sides are perforated so that the steam admitted to the fire is dried and superheated. On withdrawing the steam pipe, any one of the fire-bars may be removed without drawing the fire.—W. F. F.

Gas-producers; Feeding mechanism for —. C. W. Lummis, Worcester, Mass., Assignor to Morgan Construction Co. U.S. Pat. 1,274,176, July 30, 1918. Date of appl., June 28, 1915.

FUEL is fed intermittently from a hopper into a horizontal cylinder rotating in a casing, and is discharged when an opening in the side of the cylinder is over a discharge passage in the casing leading to the producer. The casing encloses not more than half of the lower surface of the cylinder, so that the latter is movable laterally. Means are provided for limiting the charge to a smaller volume than the full capacity of the cylinder, so that fuel is prevented from lodging between the cylinder and its seating during rotation.—W. F. F.

Gas producer. A. M. Taylor, Hegewisch, Ill., Assignor to General Chemical Co., New York. U.S. Pat. 1,275,789, Aug. 13, 1918. Date of appl., Feb. 10, 1916.

THE top of the producer has a stationary annular cover provided with poke-holes arranged at intervals around the central opening. A movable cover,

which rotates on a circular track on the stationary cover, carries a coal distributor and is provided with a poke-hole which registers in turn with the different poke-holes in the stationary cover. By this arrangement it is possible to distribute the coal uniformly over the entire horizontal area of the producer and to bring various portions of the producer within range of the poke-hole.—T. F. E. R.

Hydrogen and carbon-black; Process for the manufacture of —. R. H. Brownlee and R. H. Uhlinger, Assignors to American Nitro-Products Co., Pittsburgh, Pa. U.S. Pat. 1,276,487, Aug. 20, 1918. Date of appl., Jan. 21, 1914.

A SUITABLE hydrocarbon is decomposed by contact with heated refractory material in a closed chamber, in the absence of air or catalyst. After cooling, the separated carbon is collected and removed, and the hydrogen washed to remove impurities.—C. A. M.

[*Mineral*] *oil refining apparatus*. F. E. Wellman, Assignor to The Kansas City Gasoline Co., Kansas. U.S. Pat. 1,273,966, July 30, 1918. Date of appl., July 22, 1916.

LIQUID hydrocarbons are heated in a vessel and the vapours conducted to a condenser at a higher level, having a discharge pipe provided with means for drawing off the different fractions. This pipe is also connected with a pump for drawing off the heavier hydrocarbons, which are then cracked by means of a connected superheating coil. The resulting fractions are separated by means of a dephlegmator and condenser, and the heavier uncracked hydrocarbons from the dephlegmator are conducted back to the original source of supply.—C. A. M.

[*Mineral*] *oil-refining apparatus*. F. E. Wellman, Assignor to The Kansas City Gasoline Co., Kansas City, Kans. U.S. Pat. 1,275,337, Aug. 13, 1918. Date of appl., July 22, 1916.

A RETORT for high temperatures and pressures is contained in a housing adjacent to which are bomb-proof operators' and cleaners' vestibules, provided respectively with observation connections and bomb-proof closures communicating with the interior of the still-housing. Independent underground passages, the entrances to which are bomb-proof houses situated at a distance from the still, communicate respectively with all the operators' vestibules and with all the cleaners' vestibules.—T. St.

Gasoline; Process of producing —. J. C. Black, Los Angeles, Assignor to Standard Oil Co., Richmond, Cal. U.S. Pat. 1,275,648, Aug. 13, 1918. Date of appl., Feb. 21, 1916.

IN the fractional distillation of petroleum a fraction having an initial boiling point lower than the final boiling point of the gasoline fraction, and Beaumé gravity lower than that of the gasoline fraction, is caused to absorb natural hydrocarbon gas at approximately normal temperature. It is then possible by redistilling the gas-treated material to obtain a fraction which is identical in its gravity, boiling point range, and vapour tension, with the gasoline fraction.—T. St.

Aromatic hydrocarbons [from petroleum products]; Process of obtaining —. F. B. Holmes, Woodbury, N.J., Assignor to E. I. du Pont de Nemours and Co. U.S. Pat. 1,276,219, Aug. 20, 1918. Date of appl., Apr. 27, 1915.

GASOLINE containing aromatic hydrocarbons is treated with a liquid aromatic nitro-compound of

a higher degree of nitration than the mono-nitro-compound, and capable of causing the gasoline to separate into two parts, one of which contains a higher and the other a lower percentage of aromatic hydrocarbons than did the original gasoline.

—T. St.

Fuels; Liquid —. F. C. Axtell, New York. Eng. Pat. 109,805, Sep. 6, 1917. (Appl. No. 12,809 of 1917.) Under Int. Conv., Sep. 5, 1916.

SEE U.S. Pat. 1,201,638 of 1916; this J., 1916, 1254. (Reference is directed, in pursuance of Sect. 7, Subsect. 3, of the Patents and Designs Act, 1907, to Eng. Pats. 17,841 of 1907, 28,072 of 1913, and 2515 and 18,225 of 1914; this J., 1908, 994; 1915, 860, 948, 1001.)

Paraffin; Process of purifying —. *Process of saturating oils. Purifying oils*. A. M. McAfee, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pats. 1,277,092, 1,277,328, and 1,277,329, Aug. 27, 1918. Dates of appl., June 10, 1918, Dec. 6, 1915, and Mar. 22, 1918.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Acetic acid and acetone. Hibbert. See XX.

PATENTS.

Retorts for the destructive distillation of sawdust, shavings, small wood, peat, beans, nuts, and like carbonaceous substances; Mechanical —. Blair, Campbell, and McLean, Ltd., J. K. Ross, and E. P. Corner, Glasgow. Eng. Pat. 118,960, Dec. 13, 1917. (Appl. No. 18,478 of 1917.)

A VERTICAL retort is provided with a series of superposed trays and with a central rotating vertical shaft carrying horizontal arms, which revolve over the trays. The material to be carbonised is fed in at the top and travels round each tray towards a slot through which it passes to the next lower tray, the residue being discharged at the bottom. An annular space is formed around the shaft at each tray for the passage of the distillation products. Successive arms in each set are arranged at different heights. In an alternative form of apparatus the trays are rotated and the arms remain stationary.—T. F. E. R.

Coal; Apparatus for distillation of —. J. L. Grallin, Astoria, N.Y. U.S. Pat. 1,274,033, July 30, 1918. Date of appl., Nov. 20, 1917.

A VERTICAL retort is heated by hot gases from a furnace, which pass through zig-zag flues surrounding it. The retort extends below the lowest part of the flue, so that direct heating of this part is avoided. The base of the retort carries a false bottom within the cooler zone, and means are provided for drawing off liquid from the space between the false bottom and the bottom.

—W. F. F.

Calcium acetate and by-products; Process and apparatus for making —. J. Gendreau, Shanghai, China. U.S. Pat. 1,276,643, Aug. 20, 1918. Date of appl., May 3, 1918.

WOOD distillate containing methyl alcohol, acetic acid, and tarry material less volatile than acetic acid, is caused to flow down an inclined conduit and is heated by a heating fluid out of contact

with it. The tarry matter passes out at the bottom, and the volatilised alcohol and acid pass into the lower end of an inclined absorbing conduit mounted on the vaporising conduit. Milk of lime flows down through the absorbing conduit, and the vapour passes upwards and repeatedly bubbles through it by the aid of suitable baffles. The milk of lime is kept hot by the vapour and by contact with the vaporising conduit, and the alcohol, which is not absorbed, passes out by a pipe at the top to a condenser. The acetate solution is collected at the bottom.—W. F. F.

Electrode for arc lamps. G. M. Little, Pittsburgh, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,274,725, Aug. 6, 1918. Date of appl., Aug. 6, 1915.

An electrode for arc lamps is formed of transverse layers of dissimilar materials arranged alternately in the form of rings disposed upon a central support, so as to provide a constant supply of slag-forming material at the arc, and retard the transference of heat therefrom.—B. N.

III.—TAR AND TAR PRODUCTS.

Coal tar industry; Methods of analysis used in the —. I. Crude tars. J. M. Weiss. J. Ind. Eng. Chem., 1918, 10, 732—738.

A LIST is given of methods suitable for the analysis of crude tars; many of these methods are already widely used. Particular attention is given to sampling, and four methods, applicable to specific cases, are described. Water is determined by distillation with naphtha. The tar is dried for use in subsequent determinations by distilling it up to 170° C., separating any oils in the distillate from the water, and returning these oils to the tar. The dry tar is used for the determination of sp. gr., free carbon (insoluble in benzene), fixed carbon, ash, and viscosity (Engler viscometer). Sulphur is determined by ignition with a mixture of magnesium and sodium carbonate and oxidation to sulphate.—W. P. S.

Phenol; Synthetic —. A. G. Peterkin. Amer. Inst. Chem. Eng., June, 1918. Chem. and Met. Eng., 1918, 19, 255—260.

THE method of Dennis and Bull (U.S. Pats. 1,211,923, 1,212,612, 1,227,894, 1,228,414, 1,229,593, and 1,247,499; this J., 1917, 208, 382, 866; 1918, 52a) for the sulphonation of benzene is founded on the discovery of the former that, although the solubility of pure sulphonic acid in benzene is negligible, benzene can dissolve from a mixture of sulphuric and sulphonic acids between 2 and 3% of its volume of the sulphonic acid. A process has been devised in which sulphonation and extraction of the sulphonic acid proceed simultaneously. Benzene at 60° C. is passed continuously through a series of four "extractors" containing solutions of sulphuric and sulphonic acids in varying proportions. When all the sulphonic acid has been removed by the benzene from the first extractor, the residual acid, consisting of 77% sulphuric acid, is withdrawn and the acid charges of the remaining extractors are dropped to the next of the series, the last extractor being charged with 98% sulphuric acid. On leaving the last of the extractors, the benzene, which contains about 2% of sulphonic acid, passes on to a series of three washers in which the sulphonic acid is dissolved out by means of water. The washers work on the same principle as the extractors, i.e., as soon as the first of the series contains sufficient sulphonic acid in solution,

the liquid is removed to an evaporator and the remaining charges are moved on to the next washer of the series, the last being filled with water. In the evaporator, the small portion of benzene remaining in solution is removed and the solution neutralised, either with the sodium carbonate solution from the phenol blowers or with solid sodium sulphite. The sodium benzene-sulphonate obtained contains from 5 to 6% of sodium sulphate. The benzene from the washers passes through a separator in which any sulphonic acid solution mechanically carried over settles out; it then passes through heaters and back to the extractors. The process has many advantages over the old discontinuous method of sulphonation: initial cost of plant is reduced to one-half; labour is considerably reduced; a better yield is obtained; the formation of disulphonic acid and of sulphone is negligible; the quantity of material required is considerably less and thus a great reduction of tonnage to be transported is effected. Another improvement in the manufacture of synthetic phenol has been effected by the adoption of the so-called "liquid fusion" in which the sodium benzenesulphonate is introduced as a saturated solution into liquid caustic soda at a point above the reaction temperature. For neutralisation of the sodium phenolate, the use of carbon dioxide generated from limestone is recommended as being the most economical method.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

Indigo; Practical observations on the determination of —. W. Heinisch. Färber-Zeit., 1918, 29, 183—184, 194—197.

THE best technical method for the determination of indigotin is by titration with permanganate. The results vary according to the dilution at which the titration is made and the oxidation cannot be expressed in terms of a simple chemical equation;

nevertheless the titration can be sharply standardised, and hitherto it has been usual to employ a highly purified sample of indigoth for this purpose. Experiments show that constant titration values are obtained at any dilution exceeding 1 part of indigoth to 18,000 of water. The author recommends a dilution of 1:25,000 as a standard for all titrations. As regards the course of the oxidation reaction, it has always been assumed that 1 mol. of indigoth takes up 2 atoms of oxygen to form isatin, but careful experiments by the author show that the decolorisation is complete at a point equivalent to exactly 90% of this amount of oxygen, i.e., that 10 mols. of indigoth are oxidised by 18 atoms of oxygen instead of by 20. It is therefore possible to carry out the analysis of indigo without having recourse to a pure standard sample, by using permanganate standardised in any known manner, for instance against ferrous ammonium sulphate, potassium tetroxalate, or crystallised oxalic acid. The following procedure is prescribed: 0.3–0.5 gm. of the finely powdered sample is warmed at 70°–80° C. with 10 c.c. of concentrated sulphuric acid in the presence of 50 grms. of garnets for half an hour and the solution is made up to 500 c.c. Twenty-five c.c. of the solution is measured out into each of two beakers and diluted with 300 c.c. of water. Both are then incompletely titrated with permanganate (100 c.c.=0.539 gm. of ferrous ammonium sulphate=0.1 gm. of indigoth) until only a faint green colour is perceptible; 0.1 c.c. of permanganate is then added to beaker A which, when compared against a white ground with beaker B, will show a slightly paler green; 0.2 c.c. is next added to beaker B, so that it now shows the paler tint. Then after bringing A to the same tint by the addition of 2 drops of permanganate, 1 drop more in either will completely discharge the colour of the indigoth. This method of comparing tints is the only one by which a definite end point can be accurately judged in the presence of the residual reddish colour of most samples of natural indigo.—J. F. B.

Logwood extracts; Analysis of —. G. Savini. *Annali Chim. Appl.*, 1918, 10, 26–32.

Water: 5 grms. of the extract is heated for 6 hours at 105° C. in a platinum basin 10 cm. in diameter. *Ash*: The residue from the determination of the water is heated for about 1 hour in an oven above 105° C., the temperature being gradually raised to 170°–180° C. The incineration is then completed in a muffle, care being taken to avoid fusion of the ash. *Sugars*: 40 grms. of fluid extract or 0.2 gm. of dry extract is dissolved in about 100 c.c. of boiling water, 50 c.c. of basic lead acetate solution added, with vigorous shaking, and the liquid rapidly cooled, and made up to 200 c.c., with an additional 15 to 20 c.c. of water to compensate for the volume of insoluble substances (20 c.c. for extracts containing less than 10% of sugar, and 15 c.c. for those containing more than 10%). The flask is shaken, the liquid filtered rapidly, and 100 c.c. of the filtrate treated with a concentrated solution of sodium sulphate and phosphate to precipitate the lead, made up to 150 c.c., and filtered. Sucrose is determined in the filtrate by Clerget's method, and reducing sugars by the usual method. *Detection of molasses*: Pure logwood extracts yield a relatively small amount of ash (about 2%), about a quarter of which consists of potassium carbonate, whilst molasses contains about 6 to 7% of potassium carbonate. The amount of potassium carbonate may be rapidly determined by titrating the alkalinity of the soluble ash with N/10 sulphuric acid, the results being in close agreement with those obtained by gravimetric determination of the potassium. In the case of adulterated samples the amount of potassium carbonate should

correspond with the amount of sucrose in the extract, taking 50% as the average quantity of sucrose in molasses. In doubtful cases, such as extracts adulterated with tannin extract and containing sulphurous acid, the potassium should also be determined gravimetrically.—C. A. M.

Colouring matter as indicator. Marini. See XXIII.

PATENTS.

Colouring matter [Vandyke brown]; Manufacture of organic — and of pigments therefrom. W. A. Alsebrook, Derby. Eng. Pat. 118,735, Nov. 7, 1917. (Appl. No. 16,246 of 1917.)

ABOUT equal parts of finely powdered leather waste and 33% caustic soda lye are ground together for about half-an-hour until the product becomes solid and is soluble in water; the reaction takes place more readily if the mixture is heated not above 70° C. A pigment is prepared from the soluble colouring matter by mixing the solution with a substratum such as silica and precipitating with aluminium sulphate. If calcium sulphate be used as substratum no aluminium salt is required. If the leather waste be contaminated with cellulose waste, an alkaline oxidising agent such as a hypochlorite or peroxide is added to the caustic soda solution.—J. F. B.

Dyes [with soap]; Universal — and method of producing same. C. C. Huffman, Assignor to Sunbeam Chemical Co., Chicago, Ill. U.S. Pats. (A) 1,274,046, (B) 1,274,047, (C) 1,274,048, (D) 1,274,049, July 30, 1918. Date of appl., Sep. 24, 1917.

(A) A UNIVERSAL alkali-proof blue dye is prepared by saponifying a vegetable oil with a quantity of sodium hydroxide solution (sp. gr. 1.40) in excess of that required for saponification, and adding a solution of Methylene Blue to the mixture just before saponification is complete. (B) A yellow dye is prepared in a similar manner by the addition of a solution of Chrysoidine to the soap stock. (C) A brown dye is prepared by adding separately to the soap stock solutions of dyestuffs in the following proportions: 7.5 parts of Aniline Acid Red, 7.5 parts of Chrysoidine Yellow, 5 of Direct Black, and 0.5 of Methylene Blue. The reaction following the addition of each colour must be substantially complete before the next is added. (D) A red dye is prepared by adding a solution of Aniline Acid Red to the soap stock just before complete saponification and then raising the temperature of the mixture to 122° F. (49° C.).—J. F. B.

Naphthol [sulphur] dye and process of making same. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,274,351, July 30, 1918. Date of appl., Jan. 2, 1917.

β -NAPHTHOL or a mixture of naphthol and dinitrophenol is fused with sulphur and alkali or an alkali sulphide between 160° and 180° C. for about 5 hours to produce a black or dark-coloured dye-stuff.—J. F. B.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Silk; Degumming of — without soap. E. Ristenpart. *Färber-Zeit.*, 1918, 29, 181–182.

According to a process of Voigt and Buschhüter (Ger. Pat. 291,159; this J., 1916, 833) silk may be degummed by saturating it with a solution of an

alkali salt of a weak acid, *e.g.*, sodium carbonate, and steaming. The addition of 0.5 gm. of Monopol soap per litre is an advantage, and after steaming, especially in the case of yellow silks, the goods are rinsed out in cold water and preferably washed in a hot soap bath to remove the residues of gum and colouring matter. The soap bath may be used repeatedly and afterwards employed for dyeing purposes. Experiments made by this process to determine the most favourable concentration of alkali showed that the degumming action of the soda depends on the proportion of soda to silk and also on the concentration of the soda. For any given concentration of soda solution a certain minimum quantity of alkali must be present to effect complete degumming and the presence of an excess has no useful result. With decreasing concentrations of soda the minimum quantity required for degumming also decreases. Thus, for a concentration of 1% of sodium carbonate, the minimum quantity of soda required lies between 1.64 and 2.35% of the weight of the silk; for 0.5% concentration the quantity required is between 0.85 and 1.43%; and for 0.2% concentration it is between 0.54 and 1.0%. On the large scale centrifuges are used, and the quantity of soda required depends on the quantity of soda solution left in the goods after centrifuging. If the silk is centrifuged so as to retain twice its weight of solution, the concentration of the latter should be 1%; if centrifuged to retain 2.5 times its weight of liquid, the concentration should be 0.5%; and if it retains 3 times, the concentration should be 0.2%. The above variations are explained by the increased hydrolytic dissociation of the carbonate ions into bicarbonate and hydroxyl ions, which takes place with decreasing concentration. The extension of the principle is limited by the danger of uneven saturation when larger quantities of liquid are left in the goods. Since only the necessary quantity of soda is used to combine with the sericin, there is no danger of the fibroin being attacked and all traces of alkali are removed in the washing.—J. F. B.

Artificial silks: The cross-sections of —. De Chardonnnet. *Comptes rend.*, 1918, 167, 489–491.

The cross-sectional contours of artificial silks are a characteristic indication of the physical conditions of spinning and therefore a useful guide in the identification of origin. The first basis of classification is the manner of coagulation, *viz.*, coagulation by evaporation in air and coagulation by precipitating liquids. Other things being equal, threads formed by precipitation tend to be neither so strong nor so transparent as those formed by evaporation, since precipitation implies discontinuity. As a rule the silks formed by precipitation show a more or less circular contour in the cross-section; those produced by drying show peculiarities which influence their industrial application. Collodion silks are produced by the Chardonnnet process in both ways. When spinning by coagulation in water, a very fluid collodion is employed containing, for instance, 50 grms. of pyroxylin per litre of alcohol-ether. When the fluid thread emerges in a cylindrical form from the spinning orifice its surface is immediately coagulated on contact with the water, and the film so formed, although very thin, preserves its integrity and, during the drying of the thread, it is folded up on itself as the cross-sectional area is reduced to correspond with the final solid volume. The cross-sections of threads spun under such conditions show re-entrant angles and have generally a stellate contour. If a thicker collodion be spun in the same way, the ratio between the original volume and the final volume of the thread is not so large and the irregularities of the cross-section

are less pronounced. With a little practice, the concentration of the collodion may be estimated by an examination of the sections. When spinning into air, very much thicker collodions are employed, *e.g.*, 200–250 grms. of hydrated pyroxylin, containing about 26% of water, per litre of solvent, and, on the one hand, coagulation takes place far less rapidly, while on the other, the final solid has a larger sectional area. Hence it follows that the contour is much less wrinkled and the sections have a flattened curved shape. The “covering power” of the silk increases in inverse ratio to its apparent density and, other things being equal, silks with round and regular contours cover less space. In this respect the collodion silks, particularly those spun in water, possess an advantage; but other considerations have favoured the process of spinning in air, and the superior covering power of these threads is sufficient to compensate for the slight difference in real density as compared with natural silk. Laboratory samples of extreme fineness having perfectly circular cross-sections may be prepared from a solution of 2–3 grms. of pyroxylin in 60 grms. of alcohol and 40 of ether by spinning into dilute alcohol. The alcohol retards the drying of the surface of the thread, so that the centre dries as fast as the periphery and the cylindrical form is preserved.—J. F. B.

Cellulose of cereal straw; Nature of the —. II. E. Heuser and A. Haug. *Z. angew. Chem.*, 1918, 31, 166–168, 172–176. (See also this J., 1918, 365 A.)

The crude cellulose prepared by the chlorination method with the use of caustic soda (*loc. cit.*) contained only 0.35% of ash, whereas that prepared with the use of sodium sulphite contained 1.1%. The yield was 54.60% of crude cellulose with furfural value 13.30%, equivalent to 22.34% of xylan. Hence the calculated yield of true cellulose was 42.97%. The original straw had furfural value 15.4, equivalent to 25.62% of xylan on the dry and ash-free basis; thus 47.32% of the original xylan remained in the cellulose. The proportion of xylan remaining in the cellulose varies inversely as the yield of cellulose and is a function of the concentration of the caustic soda solution used for extracting the chlorinated products. For instance the furfural value of 13.3 was found when a 1% solution of caustic soda was employed; with a 2% solution the furfural value of the crude cellulose fell to 10.4, and with a 3% solution to 9.3. The furfural value of commercial straw cellulose also varies with the yield and with the severity of the chemical treatment; it may reach 18%. Most of the xylan may be removed from the crude straw cellulose preparations by repeated extraction with 6% caustic soda solution, but it has not been found possible to reduce the furfural value of the cellulose below 1.35% in this manner. Attempts to remove the whole of the xylan by extraction before chlorination as well as afterwards led to a similar result, and a fully extracted preparation from commercial bleached straw pulp still gave 2.02% of furfural. Commercial bleached straw cellulose shows a “copper value” of 3.0; unbleached straw cellulose on the other hand has a “copper value” of 0.94–0.99, and bleached straw cellulose which has been fully extracted until the furfural value is reduced to the limit of 2.0% shows a “copper value” of only 0.61–0.78. Moreover, by further bleaching and the production of oxycellulose, the “copper value” of this product may be increased to 15.5 without any effect on its furfural value. Hence it is concluded that straw cellulose does not correspond to a special type of “natural oxycellulose” but is an ordinary cellulose similar to that of cotton or wood, strongly contaminated with

a pentosan and modified by bleaching under industrial conditions in such a way that the commercial pulp contains a substantial amount of oxycellulose. The only outstanding question is the nature of the residual 2% of furfural which cannot be eliminated by extraction of the purified cellulose. On hydrolysis with 1% sulphuric acid at 135° C. for half-an-hour, this furfural-yielding residue is divided half in the hydrolysed liquid and half in the hydro-cellulose. An examination of the liquid and the preparation of the benzoate and osazone, m.pt. 160°—180° C., suggested the presence of xylose, and it is probable that the residue in question consists merely of a trace of xylan, equivalent to less than 1% of furfural, which is obstinately retained by the cellulose, whilst 1.0—1.5% of furfural may be attributed to the cellulose itself, just as in the case of cotton cellulose. Hydrolysis with 72% sulphuric acid followed by digestion of the diluted liquid at 120° C. for 2 hours, according to the method of Ost and Wilkenig (this J., 1910, 688), was carried out on the purified straw cellulose. The results were compared with those obtained with pure dextrose, observations being made of cupric-reducing power, polarisation, yield of alcohol by fermentation, and the m.pt. of the osazone. These were all in close agreement and afforded satisfactory evidence that the resolution of straw cellulose to dextrose is practically complete and that its constitution corresponds with that of cotton cellulose.—J. F. B.

Alcohol from sisal waste. See XVIII.

PATENTS.

Waste products [textiles from oil cloth]; Process of recovering —. J. M. Moness, Long Island City, N.Y. U.S. Pat. 1,274,184, July 30, 1918. Date of appl., Mar. 31, 1917.

THE textile base of materials such as oil-cloth is recovered by digesting the cloth with a cold 1 to 5% solution of caustic soda. The textile fabric so obtained is washed and bleached.—C. A. K.

Peat; Process and apparatus for treating —. C. Bouillon, Paris. Eng. Pat. 118,993, Mar. 15, 1918. (Appl. No. 4622 of 1918.)

PEAT is fed from a hopper into a machine with rollers in which it is milled and crumbled, whence it passes on to a draining transporter which conducts it to a tank containing a solution capable of coagulating blood, e.g., a dilute solution of calcium or ferric chloride. The mixture is then led into a rotary sieve capable of retaining the vegetable fibres which are collected by the aid of water and a "launder." Several of such rotary sieves with wires of different meshes may be used in succession. The impurities are then separated out in a settling tank in which a movement may be given to the liquid by the aid of a piston moving in a cylinder near to the tank, which is provided with small partitions forming compartments. Afterwards the peat is washed free from the calcium chloride and dried.—J. F. B.

Cellulose, particularly wood cellulose; Process of producing soda —. Aktiebolaget Cellulosa, Stockholm. Eng. Pat. 116,288, May 27, 1918. (Appl. No. 8750 of 1918.) Under Int. Conv., June 1, 1917.

WOOD is digested with caustic soda without the use of sodium sulphide by carrying out the process in the presence of a contact substance favouring reduction. Mercury is especially suitable for this purpose. The digestion liquor employed is weaker

than that commonly used and should contain about 60 grms. of Na₂O as caustic soda per litre. To maintain this dilution and provide sufficient alkali for the digestion, the wood may either be boiled with about double the usual quantity of lye or a portion of strong caustic lye may be added later in the process when the initial portion is exhausted. The principal extraction of the incrusting substances should take place at a temperature not exceeding 170° C. and the process may be accelerated by the application of air pressure. The action of the lye may be moderated by the addition of a certain proportion of waste lye, preferably freed from lignin by precipitation with carbon dioxide.—J. F. B.

Celluloid; Manufacture of non-inflammable —. H. Dreyfus, London. Eng. Pat. 118,891, Sep. 14, 1917. (Appl. No. 13,208 of 1917.)

NON-INFLAMMABLE celluloid masses, particularly those having a basis of cellulose acetate, are subjected in the course of manufacture to pressures of 300 kilos. per sq. cm. and upwards, which is at least double the pressure usually employed. The resistance of the material to weather, chemicals, etc., is considerably increased.—J. F. B.

Dentifrice [from cellulose hydrate] and method of making the same. W. F. Spies, New York, and H. D. Pease, Richmond Hill, N.Y., Assignors to L. V. Slight, New York. U.S. Pat. 1,275,779, Aug. 13, 1918. Date of appl., Dec. 20, 1917.

A NON-ABRASIVE, hygroscopic dentifrice powder with a basis of finely divided non-structural cellulose hydrate is prepared by changing viscose into a gelatinous mass, e.g., by treating viscose solution with an acid salt, such as sodium bisulphate, drying and pulverising the precipitate, washing the powder until neutral or slightly alkaline, and then drying and impregnating it with xylol or other antiseptic.—C. A. M.

Cellulose acetate; Preparation of —. G. J. Esselen, jun., Swampscott, and H. S. Mork, Brookline, Assignors to Chemical Products Co., Cambridge, Mass. U.S. Pat. 1,275,884, Aug. 13, 1918. Date of appl., Mar. 6, 1918.

CELLULOSE is acetylated without destroying its fibrous form, the excess of acetic anhydride is separated from the acetylated product, the fibrous cellulose acetate is dissolved and further treated in an acetic acid solution containing a catalyst until the desired degree of solubility is obtained, and the acetone-soluble variety of cellulose acetate is precipitated in granular form.—J. F. B.

Paper; Device for testing the tearing strength of —. R. O. Wood, Brookline, Assignor to A. D. Little, Inc., Boston, Mass. U.S. Pat. 1,273,972, July 30, 1918. Date of appl., May 5, 1917.

THE sheet of fibrous material is held firmly along a straight-edge, and means are provided for moving a lever connected with the gripping device up an inclined plane at an angle to the base-plane of the straight-edge, the force required to move the lever so as to tear the sheet being indicated upon a pressure gauge.—C. A. M.

Paper article; Reinforced —. Phonograph record and method of making same. P. Poetschke, Milford, Del. U.S. Pats. (A) 1,274,323 and (B) 1,274,324, July 30, 1918. Dates of appl., (A) Nov. 5 and (B) Nov. 12, 1917.

(A) SHEETS of paper, perforated and non-perforated, are combined to form a laminated mass with an associated body of mineral cementitious material

consisting of magnesium oxide and silicic acid reduced to a plastic condition by magnesium chloride; the outer surface may be coated with a waxy, resinous, water-repellent substance. (B) A sound record is made by building a body of layers of fibre sheets with a cement of magnesium oxychloride and a filler, subjecting the body to pressure, allowing it to harden, and applying a record-receiving facing.

—J. F. B.

[Paper] machine; Fourdrinier —. J. Alpine, Stevens Point, Wis. U.S. Pat. 1,275,826, Aug. 13, 1918. Date of appl., June 2, 1917.

THE frame of the machine is carried on a platform pivoted on a fixed bed at the receiving end and adjustably connected with the bed at other points so that the further end may be raised or lowered. The frame carries a breast roll at the pivoted end, a couch roll at the end distant from the pivoted end, and a set of suction-boxes between the two rolls. Another suction-box is supported by the platform beyond the couch roll and a take-off roll is similarly supported between the couch roll and the last suction-box, a take-off conveyor being arranged to travel over the take-off roll and the suction-box associated with it. Means are provided for adjusting the inclination of the platform and frame by lowering or raising the couch roll end and for maintaining the tension of the take-off conveyor in various positions of platform adjustment. The take-off roll swings with the platform and the conveyor passes over rolls which are in fixed relation to the bed.—J. F. B.

Paper-pulp strainers. The Watford Engineering Works, Ltd., and J. Paramor, Watford. Eng. Pat. 118,981, Feb. 7, 1918. (Appl. No. 2234 of 1918.)

Sizing composition [for paper]; Absorbent material —. E. Fues, Hanau, Germany. U.S. Pat. 1,276,206, Aug. 20, 1918. Date of appl., June 15, 1914.

SEE Fr. Pat. 473,405 and Eng. Pat. 19,816 of 1914; this J., 1915, 546, 1049.

Glucose. Eng. Pat. 118,651. See XV11.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Soluble starch for laundry purposes. O. Reinke. Chem.-Zeit., 1918, 42, 422.

SINCE rice starch is no longer obtainable in Germany, potato starch which has been rendered soluble is suggested as a substitute for starching collars, etc.—W. P. S.

PATENTS.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,275,878, Aug. 13, 1918. Date of appl., Aug. 3, 1917.

WITHIN a receptacle having non-perforated sides are two foraminous plates which can be maintained at any position of separation from each other so as to form a fibre chamber of any desired size; two outer foraminous plates are spaced respectively from the inner ones. The top of the receptacle is revolvable so as to allow access to the interior. Two series of curved tubular members open into the upper and the lower part of the receptacle respectively. There are also provided a

liquid supply tank, a pipe leading from above the upper inner plate to the liquid reserve tank and one leading from below the lower inner plate to the same tank and a pump, whereby a liquid may be pumped in opposite directions through the curved members, foraminous plates, the fibre chamber, and the reserve tank. A small testing device of similar construction is connected externally with the circulating system.—I. F. B.

Silk and other textile goods in hanks; Apparatus for treating — by means of liquids. A. W. Schmid, Basle, Switzerland. U.S. Pat. 1,277,136, Aug. 27, 1918. Date of appl., Oct. 12, 1917.

THE patent relates to mechanical means for raising, lowering, and rotating the hank support and for holding it in its raised position.

Copper compounds of substantive ortho[hydr]-oxyazo dyestuffs; Process for producing on the fibre —. E. Anderwert, H. Fritzsche, and H. Schobel, Assignors to Soc. of Chem. Ind. in Basle, Switzerland. U.S. Pat. 1,276,307, Aug. 20, 1918. Date of appl., Nov. 4, 1915.

SEE Eng. Pat. 12,932 of 1915; this J., 1917, 382.

[Aniline] Black; Production of — upon textile fibres. E. A. Fourniaux, Manchester. U.S. Pat. 1,277,056, Aug. 27, 1918. Date of appl., Aug. 9, 1917.

SEE Eng. Pat. 116,562 of 1917; this J., 1918, 463 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid manufacture; Large-scale —. A. M. Fairlie. Chem. and Met. Eng., 1918, 19, 404—408.

SULPHURIC acid is manufactured by the Tennessee Copper Co. by the chamber process, from the waste fumes of copper blast furnaces. There are two plants, one of two units and one of one unit, each unit having a daily capacity of 300 tons of acid of 60° B. (sp. gr. 1.71). The flue leading from the blast furnaces to the Glover towers has a sectional area of 200 sq. ft., and a length of 200 ft. to No. 1 plant, and 500 ft. to No. 2 plant. The waste gases contain 3—6% SO₂ and vary in temperature between 600° and 900° F. (315°—480° C.) at the entrance to the Glover towers. To avoid the stoppage of plant due to the partial blocking up of the flue by deposits of nitre caused by leaking or overflowing of the nitre-pots, a system of external fire-heated retorts is used. These retorts, 10 ft. in height and 8 ft. in diam., take 1000 lb. of nitre and are fed automatically with sodium nitrate and sulphuric acid in the correct proportions. The Glover towers are octagonal in shape and are 55 ft. high and 30 ft. in diam. The lead curtains are lined with "chemical brick," laid in acid-proof cement. The chamber acid is concentrated to 60° B. (sp. gr. 1.71). No. 1 plant is provided with 34 lead chambers, 67—77 ft. high, of a total capacity of 3,944,800 cub. ft. No. 2 plant has four large chambers, 40 ft. high, with a total capacity of 2,227,840 cub. ft. The chambers are fitted with the usual thermometers and hydrometers, and the process is also regulated by the special analytical method of chamber control devised by the author (this J., 1917, 196). The Gay-Lussac towers of No. 1 plant have lead curtains lined with acid-proof brick walls. They are eleven in number, and are of various dimensions. No. 2 plant has only one Gay-Lussac tower, and

this is without lead curtains. It is built of acid-proof brick laid in acid-proof cement, and is divided into 56 compartments provided with a special system of acid feed pipes. No advantage has been obtained by the use of this type of tower. Large lead-antimony blowers are used to supplement the furnace blast pressure in forcing the gases through the chambers. Blow-cases constructed of riveted wrought iron are used for elevating the acid. Coolers of special design have been devised to deal with the large quantities of acid from the Glover towers. Atomised water is used in the chambers instead of steam, an electrically driven atomiser, capable of atomising 50 galls. of water per hour, being employed.

—S. S. A.

Nitric acid manufacture in the United States; Development in — since 1914. E. J. Pranke. Chem. and Met. Eng., 1918, 19, 395–396.

It is computed that the production of nitric acid (calculated as 100% acid) from sodium nitrate has increased from 89,000 tons to 650,000 tons since 1914, and that in the spring of 1919 the ammonia-oxidation plants now under construction will be producing at the rate of 225,000 tons of 100% acid per annum. This gives a total of 875,000 tons of 100% acid, or about nine times the pre-war production. The erection of many new nitric acid plants using sodium nitrate has provided opportunity for improvements to be made. The installation of modern fire-boxes in place of Dutch ovens under the retorts has effected a reduction in coal consumption of 25%. Acid-proof iron has been largely used to replace chemical stoneware, and a larger absorption tower capacity has been provided. The average charge of nitrate has been increased 50%. These improvements, together with modifications in the method of operation, have effected an increase in the amount of nitrogen recovered as nitric acid from about 78–80% to 92–94%. Progress is recorded in the recovery of nitrous gases from nitration units. In the ammonia-oxidation process, the catalyst used in several of the new plants is a single fine platinum gauze, with an area of about two square feet, electrically heated. Another type of catalyst, adopted by the Government experimental plants at Sheffield, Alabama, consists of several layers of platinum gauze, welded together at points, and rolled into the form of a cylinder. This is not electrically heated, the heat of reaction maintaining the necessary temperature after the oxidation has been started by external heating. No figures are available for comparison of the efficiencies of these catalysts. The cost of production of concentrated nitric acid from sodium nitrate and from autoclave ammonia gas is about the same, but ammonia gas is a cheaper form of nitrogen than sodium nitrate, so that the total cost is less with ammonia. This difference in the cost of the production of the acid rather than considerations relating to plant will probably be the decisive factor in determining whether in the future the ammonia-oxidation process will replace the older process.

—S. S. A.

Oxalic acid; Titration of — by the conductance method. H. S. Harned and C. N. Laird. J. Amer. Chem. Soc., 1918, 40, 1213–1218.

If the electrical conductivity of a solution of oxalic acid is measured at successive stages in the addition of a CO₂-free sodium hydroxide solution, there is found to be a sharp change in the direction of the curve, which is obtained by plotting conductivity against the quantity of added alkali, when the formation of the acid oxalate is just complete. The change in the direction of the curve

at this point varies with the dilution and becomes less distinct with increasing concentration. When the oxalic acid is dissolved in 50 c.c. of water, and titrated with N/10 sodium hydroxide, the conductance method gives a sharp end point for quantities of oxalic acid up to 0.3 gram. By the use of N/2 sodium hydroxide, quantities not exceeding 0.8 gram, may be satisfactorily titrated. If the sodium hydroxide is not free from carbonate, the method yields high results. It is probable that the method is applicable to other dibasic acids comparable in strength with oxalic acid and may be used in the titration of mixtures of the acids and acid salts with sodium hydroxide or in the titration of mixtures of the acid salts and neutral salts with hydrochloric acid.—H. M. D.

Potash from kelp; Extraction of —. C. A. Higgins. Chem. and Met. Eng., 1918, 19, 432–433.

The extraction of potash from seaweed by incineration is very costly, and will probably continue only as long as the present high price of potash is maintained. Even under modern methods, the cost of harvesting alone, in Californian coastal waters, amounts to about \$1.10 (4s. 7d.) per ton of raw kelp containing 1.3% K₂O; which is equivalent to about \$85 (say £18) per short ton of K₂O, without the cost of drying and incineration. In a process operated successfully by the Hercules Powder Co., San Diego, Cal., since 1915, raw kelp is fermented with the production of acetic acid. Fermentation is allowed to proceed until the greater part of the kelp leaf dissolves, when the insoluble residue is removed by screening, and the solution is then neutralised with limestone. The liquid is concentrated and three products are obtained at various stages, the first consisting mainly of calcium acetate and potassium chloride, the second of the calcium salts of acetic, propionic, butyric, and valeric acids, and the third containing the bulk of the potassium iodide. The first product is distilled to recover acetone and acetone oils, and the residue lixiviated for potassium chloride; the second is treated with alcohol and sulphuric acid for the production of ethyl esters which are afterwards separated by fractionation; and the third is treated with chlorine for the production of iodine which is subsequently recovered by sublimation. The residual unfermented leaves are treated with sodium carbonate to extract, in the form of a soluble salt, algin which is afterwards precipitated and purified. Algin may find extensive uses in the future as a substitute for gelatin and vegetable gums. Probably the total production of all the harvesting concerns in present operation (in the U.S.A.) does not exceed 25 tons of 80% potassium chloride per day; and of this more than half is recovered in the form of high-grade salt (95% KCl) by the fermentation process.—W. E. F. P.

Potash recovery; The Cottrell process for —. L. Bradley. Chem. and Met. Eng., 1918, 19, 457–460.

The recovery of potash as a by-product in the iron and cement industries is briefly reviewed, special reference being made to the iron ores of Alabama as potential sources of potash, and to the use of potash-bearing silicates, such as feldspar and the Cambrian slates of Georgia, in the manufacture of Portland cement.—W. E. F. P.

Gas works; Analysis of spent purifying materials from —. Wentzel. Z. angew. Chem., 1918, 31, 176.

The author criticises the agreement recently made between the Deutsche Gold und Silberscheidanstalt and the German gas works (this J., 1918,

465 A). He contends that a quantity of 25 grms. is far too little to afford a good average sample for the determination of moisture. The absolute moisture content of the material cannot be accurately determined on account of the decomposition of the ferrocyanide, and many large gas works base their results on the air-dried material. The method proposed for the determination of crude sulphur is criticised on account of the large inaccuracies of the volumetric methods of measurement adopted and the high volatility of the solvent (carbon bisulphide) employed. On the other hand, the Drehschmidt method is said to be satisfactory and accurate, being based on gravimetric principles; differences up to 6% of sulphur have been found by the two methods and always settled in favour of the Drehschmidt method. The oxidation by fuming nitric acid presents no difficulties and with 0.5 gm. of substance may be completed within 4 hours with a consumption of not more than 30 c.c. of acid. In the new method about 240 c.c. of carbon bisulphide is consumed per analysis, whereas in the Drehschmidt method about 50 c.c. is used and immediately recovered by distillation.

—J. F. B.

Metastannic acid and its compounds. A. Kleinschmidt. *Monatsh. Chem.*, 1918, **39**, 149—178.

Nitric acid diluted with $1\frac{1}{2}$ —2 volumes of water dissolves tin, yielding stannous nitrate, and at 0° — 15° C. the formation of this substance can be detected even using undiluted acid, but it is then accompanied by the formation of normal or basic stannic nitrate; the yellowish white precipitate obtained between 0° and 15° C. is a mixture of a white stannic nitrate soluble in water with an insoluble yellowish-white basic stannic nitrate. Stannic nitrate at the ordinary temperature slowly changes into metastannic nitrate, the transformation being more rapid at higher temperatures. The powdery oxidation product of tin with hot nitric acid is not metastannic acid but the nitrate of this substance, $5\text{SnO}_2 \cdot 2\text{HNO}_3 \cdot 3\text{H}_2\text{O}$, which undergoes hydrolysis with water yielding metastannic acid; the nitrate obtained with cold acid has the composition $3\text{SnO}_2 \cdot 2\text{HNO}_3 \cdot \text{H}_2\text{O}$ and is probably a mixture or compound of stannic nitrate $\text{SnO}(\text{NO}_3)_2$ with metastannic nitrate, $5\text{SnO}_2 \cdot 2\text{HNO}_3 \cdot 3\text{H}_2\text{O}$, the latter of which is also obtainable by the action of nitric acid on metastannic acid. Metastannic acid and hydrochloric acid react yielding a stannyl chloride $5\text{SnO}_2 \cdot 2\text{HCl} \cdot 3\text{H}_2\text{O}$, which with sodium hydroxide gives a sodium metastannate $5\text{SnO}_2 \cdot \text{Na}_2\text{O} \cdot 4\text{H}_2\text{O}$. It is suggested that metastannic acid has the formula $\text{Sn}_2\text{O}_5(\text{OH})_{10}$, the above nitrate and chloride being represented respectively as $\text{Sn}_5\text{O}_{15}(\text{OH})_8(\text{NO}_3)_2$ and $\text{Sn}_5\text{O}_{15}(\text{OH})_8\text{Cl}_2$. (See also *J. Chem. Soc.*, Nov., 1918.)—D. F. T.

Rare earths. VII. Separation of holmium. L. F. Yntema and B. S. Hopkins. *J. Amer. Chem. Soc.*, 1918, **40**, 1163—1167.

ATTEMPTS to separate holmium from yttrium have been made by fractional hydrolysis of the phthalates. The mixed hydroxides were added gradually to phthalic acid suspended in water, the acid being kept in excess to prevent the formation of an insoluble basic compound. The proportion of phthalic acid in the resulting solution was adjusted so that hydrolysis began between 50° and 60° C., and by raising the temperature stepwise, a series of fractions of basic phthalate was obtained in which the ratio of holmium to yttrium gradually diminished. By means of four series of such hydrolyses, the holmium content of a mixture was increased from 12% to 25.4%. Fractional precipitation by the addition of sodium nitrite to a neutral nitrate solution was also tried and in a

series of such precipitations in which ten fractions were obtained, it was found that the first fraction contained 12.5% of holmium as compared with about 4.8% in the original rare earth mixture. The nitrite method is considered the better of the two methods of separation, not only in respect of efficiency, but also of the cost of the materials used and the relative simplicity of the operations involved.—H. Sulphuric acid; Process of and apparatus for concentrating —. H. G. Klink, Moundsville, W. Va. U.S. Pat. 1,276,377, Aug. 20, 1918. Date of appl., Mar. 23, 1917.

THE weak acid is caused to pass from the top to the bottom of a tower packed with inert material, through the interstices of which a counter-current of hot air is maintained. Means for collecting the concentrated acid are provided at the lower end of the tower, and the upper end communicates with a condenser through which the gaseous current is passed. The liquid from the condenser is concentrated in a series of evaporating pans and then discharged into the top of the tower.

—W. E. F. P.

Alumina; Purified crystalline — and method of making the same. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls. U.S. Pat. 1,276,134, Aug. 20, 1918. Date of appl., Jan. 5, 1918.

A MIXTURE of aluminous material, containing between 0.1 and 1% of titanium oxide, and carbon is fused, separated from the reduced impurities, and a solid oxidising agent such as iron oxide is added and the mixture re-fused so as to oxidise the carbon and carbides present.—A. B. S.

Magnesium chloride; Process and apparatus for preparing [anhydrous] —. C. Dantsizen, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,276,499, Aug. 20, 1918. Date of appl., Apr. 22, 1916.

ANHYDROUS magnesium-ammonium chloride is charged into a bath of magnesium chloride heated electrically to above 300° C. in a closed chamber. This communicates with a second chamber in which the vaporised ammonium chloride is condensed; portions of the fused magnesium chloride are removed from the bath at intervals.—W. E. F. P.

Gases [air]; Method of treating [liquefying] —. A. C. Morrison, Essex Fells, N.J. U.S. Pat. 1,273,929, July 30, 1918. Date of appl., Apr. 4, 1914.

IN a method of liquefying a paramagnetic gas at a temperature slightly above the normal boiling point, the gas is subjected to the action of a powerful magnetic field. In the treatment of air and

other oxygen mixtures, separation is effected by causing the gas to flow at high velocity through a spiral tube located within the magnetic field, the constituents being removed separately from the outer and inner portions of the tube.—W. E. F. P.

VIII.—GLASS; CERAMICS.

Alumina; Influence of — on the fusibility of glasses. L. Springer. *Keram. Rundsch.*, 1917, 48, 243. *J. Soc. Glass Tech.*, 1918, 2, Abs., 88—89.

THE author's experiments were similar to those of Singer (this J., 1918, 582 A), except that the mixtures were heated in small crucibles in a glass furnace and the progress of fusion followed by withdrawing samples at frequent intervals. It was found that in a high-alkali glass or in a normal glass of the standard type $0.5\text{Na}_2\text{O}$, 0.5CaO , 3SiO_2 , addition of alumina, even in small quantities, decreased the fusibility and retarded the fining. In glasses high in lime and low in alkali, the fusibility was increased and the fining accelerated by addition of alumina, the effect, within limits, being in proportion to the amount of alumina added. It was immaterial whether the alumina was added as kaolin or as hydrated alumina. Inconclusive results in regard to fusibility were obtained when pegmatite was used as source of alumina, but the glasses made with pegmatite fined more rapidly in every case than those without pegmatite. The effect of alumina on fusibility appears to depend on many factors, and particularly on the composition of the glass, and no definite rule can be formulated. The total heat consumed in heating the batch materials to the maximum temperature of the melting furnace, in decomposing the sulphates and carbonates present in the batch, in melting the silicates produced, and in dissolving the excess silica is about twice as great in the case of a soda-ash batch and three times as great with a salt-cake batch as the heat liberated by chemical combination between the acidic and basic oxides of the batch. If, therefore, part of the lime and alkalis is introduced already combined as silicates, as is the case when pegmatite is used, less heat is required in the furnace to melt the glass. The heat balances for four glass batches are calculated in support of this contention.

Glass; Polishing — by means of acids. O. Parkert. *Sprechaal*, 1918, 51, 162—163.

WHEN acids are used for polishing glass instead of the customary mechanical methods with abrasive materials, the irregularities in the surface are removed by solution of the glass. Hydrofluoric acid is chiefly used, but other acids (such as sulphuric acid) may be added for subsidiary purposes such as the solution of calcium fluoride formed by the action of the hydrofluoric acid. A solution suitable for

polishing Bohemian lead glass consists of water 1 part, sulphuric acid 2 parts, and hydrofluoric acid 1 part; for other glasses the most suitable solution should be found by trial. The solution should be heated to 40° – 50° C. and maintained at that temperature. The glass is cleaned by immersion for 45 seconds in a mixture of sulphuric acid 12 parts, hydrochloric acid 1 part, and water 100 parts, and then in water at 35° C. It is then immersed for 30 seconds in the polishing solution and is afterwards washed thoroughly. If one treatment is insufficient it may be repeated. Fine glass ware may receive a final polish with the aid of tin ash. The glass ware may be etched by covering it with a stencil and exposing it to the gas evolved from the polishing solution. If the glass is not polished after 30 seconds' immersion, more hydrofluoric acid should be added to the solution. Good ventilation should be provided. This method of polishing is applicable to all kinds of glasses except the very finest ware; it is cheap and requires little skill.

—A. B. S.

Glasses and glazes; Phosphoric acid —. H. Fritz. *Chem.-Zeit.*, 1918, 42, 422.

GLASSES and glazes were prepared from mixtures of lead oxide, alkalis, lime, barium oxide or zinc oxide, and phosphoric anhydride or a phosphate. When a phosphate was used the products were not clear, but when phosphoric anhydride was used they were mostly clear and occasionally brilliant. In some cases the introduction of 0.15 mol. of Al_2O_3 made a turbid glass or glaze clear. Most of the glazes prepared with phosphoric anhydride were subject to "crazing." Brilliant glazes free from crazing were obtained, however, with a mixture of the composition $0.1\text{K}_2\text{O}$, 0.1CaO , 0.8PbO , $0.2\text{Al}_2\text{O}_3$, $2\text{P}_2\text{O}_5$.

—W. P. S.

Chemical stoneware. A. Malinowsky. *Amer. Inst. Chem. Eng.*, June, 1918. *Chem. and Met. Eng.*, 1918, 19, 485—487.

CHEMICAL stoneware is made of a mixture of several clays, selected to produce a body of porcelain-like character. Alternatively, a low-grade fireclay may be used either alone (when the ware should be burned at 1400° – 1500° C.) or in admixture with an impure clay of very low fusing point, or other cheap fluxes such as lime or furnace slag. The mixture should be high in silica but plastic enough to permit the shaping of large articles. It should have a range of 200° – 300° C. between complete devitrification and deformation. Uniformity of composition is essential and is best secured by mixing and blunging the materials with water, screening to separate the coarser particles, and then removing the surplus water in a filter-press. If the coarse particles are not removed, spigots and faucets made of the material will leak. To ascertain the solubility of chemical stoneware, weighed vessels may be filled with concentrated sulphuric acid and heated on a sand-bath at about 120° C. for 12 weeks, the acid evaporated being replaced by fresh acid. The vessels are then allowed to cool, washed with water, dried at 140° C., cooled, washed, again dried at 140° C., allowed to cool in a desiccator for 24 hours, and the loss in weight noted. In two samples tested the losses were 0.074 and 0.098% respectively. Another method consists in grinding a piece of the stoneware until it passes completely through a No. 16 sieve. The material is then screened through a No. 20 sieve and about 100 of the largest pieces left on the sieve are weighed, washed with distilled water, dried at 110° C., cooled in a desiccator and weighed. They are transferred to a platinum crucible, a mixture of concentrated nitric acid 10 parts, concentrated sulphuric acid 25 parts and water 65 parts added, boiled for about 4 hours until

all the sulphur trioxide fumes have been driven off, cooled, dilute nitric acid added and again boiled for 10 minutes. The insoluble matter is washed free from acid, dried at 110° C. for five hours, cooled in a desiccator, and the loss in weight noted. In a sample thus tested the loss was 0.56%. Microscopical examination of good chemical stoneware shows that it has a character similar to lava, and that it consists of a refractory material united by a glassy mass. The texture is sufficiently fine for a high polish to be obtained, so that spigots and stoppers may be ground to fit tightly. The chief minerals present are quartz, orthoclase, plagioclase, magnetite, and altered "ferro-magnesia mineral." The quartz grains are surrounded by a thin glassy film, but are otherwise unaltered. The felspar grains are much altered externally and gradually pass into the ground mass. The heat appears to have fractured the grains and to have fused the materials along the cracks. The original "ferro-magnesia" has been chiefly converted into magnetite and a glassy mass. The rate of cooling the ware after burning is important; too rapid cooling will produce brittle ware and too slow cooling will cause too much crystalline matter to be formed. The ware may be cooled rapidly to the freezing temperature of the eutectic (800°–1000° C.), but the subsequent cooling should be very slow.—A. B. S.

Carborundum refractories. S. C. Linbarger. Chem. and Met. Eng., 1918, 19, 489–491.

CARBORUNDUM is an important ingredient in refractory materials as it increases their thermal conductivity. It has a low coefficient of expansion, great strength and toughness, and a high specific heat, thermal conductivity, and emissivity at the

temperatures at which crucibles, saggars, and other articles made from it are used. The heat-emissivity curves of various refractories are shown in the accompanying diagram and other properties in the following table:—

Material	Specific heat	Thermal conductivity	Compressive strength, lb. per sq. in.
Firebrick	0.192	0.0034	1,050
Sagger mixture	0.187	0.0033	1,340
Magnesite	0.220	0.0071	4,800
Chrome	0.174	0.0067	3,900
Refrax	0.162	0.0275	12,500
Carbofrax	0.180	0.0243	14,700
Silica	0.191	0.0020	2,300

The form of carborundum most suitable for ceramic purposes ("carbofrax") is made by bonding graded crystallized silicon carbide with a small proportion of refractory clays to secure a dense body of low porosity with about seven times the heat-conducting power of a sagger mixture and

twelve times that of a silica brick, and a load-carrying capacity over ten times as great as that of sagger mixtures, without the same tendency to soften at high temperatures. Hence, saggars made of carborundum need only be one-tenth of the present thickness and so would be lighter and heated much more rapidly than the present ones. Carborundum refractories will also withstand the most sudden changes in temperature and are not readily attacked by the fused ash from coal. "Refrax" and "silfrax" are special products prepared by the action of vapours containing silicone on carbon or silicon carbide in an electric furnace, the final product being pure silicon carbide. Firesand or amorphous carborundum is a mixture of various silico-carbides forming the exterior of the core produced in the manufacture of carborundum. It is highly refractory and although less stable than carborundum at a high temperature has a wide application when bonded with fireclay or water-glass and made into bricks, etc., or applied as a plastic coating to protect furnace linings from the cutting action of impinging flames.—A. B. S.

PATENTS.

Glass-furnace. H. E. De Vaughn, Assignor to W. A. Jones, Morgantown, W. Va. U.S. Pat. 1,274,146, July 30, 1918. Date of appl., Oct. 6, 1916.

A skew block supporting the cap of a glass-furnace has a channel in its under side and a recess leading upward therefrom. Within the recess is a hollow flat supporting device, preferably of metal, which is suspended by bars or other means which extend upwards through passages in the block. The suspension bars are enclosed in tubes through which and through the hollow supporting device a cooling medium is circulated.—A. B. S.

Porcelain kiln. W. Mellor, Sebring, Ohio. U.S. Pat. 1,275,285, Aug. 13, 1918. Date of appl., Mar. 30, 1918.

An up-draught muffle oven has several fireboxes on one side, below the sole, connected to lateral sub-

sole flues and to vertical flues which lead to separate chimneys—one for each side of the oven.—A. B. S.

Kiln. C. H. Zwermann, Kalamazoo, Mich. U.S. Pat. 1,275,352, Aug. 13, 1918. Date of appl., June 8, 1918.

Two coal-fired tunnel kilns are placed side by side, with the inlet end of one near to the exit end of the other, the intervening wall being relatively thin and provided with a longitudinal flue. Along the outer sides of the tunnel are perforated bag walls,

the bottom of the bags communicating with the flue in the inner wall. Heating flues lead from the top of this outlet flue over the tops of the tunnels, downwardly at the outer sides towards the inlet ends of the tunnels to heat the preheating zone in each tunnel. Discharging and vertical circulating flues, open at top and bottom, for the preheating zones are placed at the outer sides of the tunnels and on opposite sides of the common wall, so as to create a cooling circulation near the exit end of each tunnel and a heating circulation near the charging end.—A. B. S.

Compartment kiln. R. H. McElroy, Assignor to The International Clay Machinery Co., Dayton, Ohio. U.S. Pat. 1,275,712, Aug. 13, 1918. Date of appl., Sep. 1, 1917.

EACH chamber in a gas-fired continuous kiln of the transverse arch type is provided with a transverse bag wall along one side, a feather-wall forming a connecting flue, and a perforated floor, portions of the floor adjacent to the bag wall being non-perforated. The connecting flues and the perforations in the floor all communicate with the main flue.

—A. B. S.

Refractory material. J. M. Allen, Assignor to Fellhauer-Allen Manufacturing Co., St. Louis, Mo. U.S. Pat. 1,275,354, Aug. 13, 1918. Date of appl., Nov. 10, 1917.

A REFRACTORY material consisting of 48½% of fireclay, 48½% of anthracite coal, and 3% of galena.—A. B. S.

Clay; Process of hydrating — J. S. Laird, Ann Arbor, Mich. U.S. Pat. 1,275,705, Aug. 13, 1918. Date of appl., Dec. 24, 1917.

CALCINED clayey material is hydrated and its plasticity is increased by subjecting it to the action of steam under pressure at a temperature above 100° C. whilst working the mass.—A. B. S.

Crystalline alumina. U.S. Pat. 1,276,134. See VII.

IX.—BUILDING MATERIALS.

Polash from cement dust; Wet process for extracting — J. G. Dean. Chem. and Met. Eng., 1918, 19, 439—447.

At the works of the South-western Portland Cement Co., Victorville, California, 1 ton of potassium sulphate per day is now being extracted from cement-kiln dust by a process in which the hot kiln gases are saturated with water vapour and then cooled to the lowest permissible temperature before discharge, so that the dust is precipitated in the form of a sludge containing potassium salts in solution. The gases are saturated with water vapour in a spray chamber, and cooled in a condenser-evaporator designed to utilise the heat of the gases for concentrating the weak solutions obtained. Owing to imperfect atomisation of the oil fuel employed, the atmosphere within the kiln is reducing; and the dusty gases contain sulphides, polysulphides, and thiosulphates, in addition to sulphates, of potassium and sodium. The sulphides are converted into sulphates, thiosulphates, and carbonates by reaction with carbon dioxide and water in the spray chamber; and the carbonates into sulphates by passing the filtered liquid through a bed of gypsum, which latter is prevented from dissolving in the alkali thiosulphate by the presence of an excess of carbon dioxide. By evaporating

the solution to crystallisation, a product consisting of potassium sulphate in admixture with a hydrous double thiosulphate of potassium and sodium is obtained which, on being dried and heated to decompose part of the thiosulphate, yields a marketable product containing about 90% of potassium sulphate. The formation of the double thiosulphate may be prevented, and pure potassium sulphate crystallised out from the boiling solutions, by the addition of sufficient sodium sulphate to the liquid at the appropriate stage. By reason of the comparatively low temperature, due to the reducing conditions obtaining within the kiln, only about 45% of the total potash in the charge is volatilised. Oxidising conditions, although producing a higher kiln temperature, would greatly increase the difficulty of handling the solutions and render the separation of the potassium and sodium salts practically impossible. At present the operating cost is nearly covered by the value of the returned dust. Details are given of the general design and operation of the plant.—W. E. F. P.

Plaster; Importance of the valuation of — E. Link. Tonind.-Zeit., 1918, 42, 525—526.

HEAVILY adulterated plasters and some plaster substitutes are now on the market in Germany. One of the former examined by the author was found to consist of plaster of Paris 38.59%, calcium carbonate 20.18%, hydrated lime 39.65%, magnesia 0.15%, and insoluble residue 1.12%. It appears to have been made by mixing plaster of Paris with dry slaked lime, the latter having absorbed carbon dioxide from the air. Its composition explains its peculiar behaviour when sprinkled into water, the low strength of the plaster, and its softness when set.—A. B. S.

Potash recovery. Bradley. See VII.

Bricks, slabs, columns, and the like; Composition and manufacture of — and structures erected therewith. A. T. O. Quick, British Expeditionary Force. Eng. Pat. 119,152, Dec. 1, 1917. (Appl. No. 17,783 of 1917.)

BRICKS, slabs, columns, or the like are made from a mixture of 4 parts of powdered chalk and 1 part of Portland or like cement by gauging with water and allowing to set in moulds. For rapid construction the bricks are made with open-ended passages and when assembled are fixed in position by cement introduced into the passages so as to form keys.

Bricks; Stepped — for the walls of buildings and acid plants. W. H. Kenyon, Haslingden, and W. Smith, Accrington. Eng. Pat. 119,687, Sep. 20, 1917. (Appl. No. 13,519 of 1917.)

Lagging. Eng. Pat. 118,871. See I.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Selenium and tellurium; Recovery of — in copper refining. M. H. Merriss and H. T. Binder. Eng. and Min. J., 1918, 106, 443—445.

IN the electrolytic refining of crude copper bullion the selenium and tellurium present are concentrated in the anode slimes, from which they are recovered in various ways. (1) The button of noble metals obtained by cupellation of the slimes with lead is fused with sodium carbonate and nitrate; the

"nitre slag," which contains the bulk of the selenium and tellurium, is extracted with hot water, giving a solution of selenite and tellurite. (2) The flue system of the cupellation furnace is equipped with a scrubber or Cottrell apparatus. In both cases it is necessary to saturate the gases with water, and the water, after being circulated repeatedly, forms a cheap source of selenium. The wet sludge from the scrubber is filter-pressed. (3) The flue-dust, or the filter-pressed sludge from (2) is roasted at a low red heat; crystals of selenium dioxide are obtained by cooling the roaster gases in chambers. (4) The flue dust, instead of being roasted, may be extracted with water, selenium dioxide dissolving. The residue is treated with sulphuric acid and bleaching powder, whereby the elementary selenium is oxidised and dissolved. The alkaline solution obtained under (1), on being acidified with sulphuric acid, yields a precipitate of tellurous acid. The acid filtrate, or the solutions obtained under (2) or (4), are reduced with sulphur dioxide to precipitate the selenium. The latter is washed free from acid and digested with boiling water to transform it into the black modification. The dried tellurous acid precipitate is reduced with lampblack or ground charcoal in a crucible furnace and cast into cake or stick form. Alternatively, the tellurous acid may be dissolved in 4 parts of strong hydrochloric acid and the solution precipitated with sulphur dioxide, the solution being diluted but not to such a degree as to re-precipitate tellurous oxide.—W. R. S.

Zinc; Analysis of commercial — L. Bertiaux. Ann. Chim. Analyt., 1918, 23, 161–169, 181–191.

LEAD is determined electrolytically as dioxide, after the sample has been dissolved in a mixture of copper nitrate solution and nitric acid. To determine iron, the metal is dissolved in sulphuric acid, and the ferrous salt titrated with permanganate solution; this gives the iron approximately, but for more accurate work, the iron may be determined colorimetrically in a portion of the titrated solution by means of thiocyanate. Tin is not often present; it may be determined in the usual way as metastannic acid. Antimony is separated from the tin by the oxalic acid method. Copper and cadmium are determined electrolytically, the latter from an alcoholic alkaline cyanide solution. Arsenic is separated by distillation and titrated with iodine solution; the residue from the arsenic distillation may also be used for the determination of the antimony. Sulphur is evolved as hydrogen sulphide which is absorbed in ammoniacal silver nitrate solution, and carbon is determined by oxidation with chromic acid and sulphuric acid, the resulting carbon dioxide being absorbed in potassium hydroxide and weighed.—W. P. S.

Zinc slags. O. Mühlhauser. Metall u. Erz, 1918, 15, 303–305.

THE amount of slag formed in the retorts during distillation should be small, and its composition should be controlled by mixing the charge in suitable proportions so that it has as little action on the retort as possible. An average slag sample obtained by distilling a mixture of Joplin and Wisconsin ores was found to have an oxygen ratio of 1:2.8, approaching that of a trisilicate. It was very viscous at distillation temperatures and formed an internal coating, the thickest part of which was on the bottom of the retort. The latter was thus protected from corrosion, and the loss of zinc by vapour diffusion decreased.—W. R. S.

Tin; Crystal structure of — A. J. Byl and N. H. Kolkmeier. Chem. Weekblad, 1918, 15, 1077–1078.

AN application of the Röntgen ray method to the determination of the crystal structure of tin.

—A. J. W.

Flotation; Effect of addition agents in — M. H. Thornberry and H. T. Mann. Bull. School of Mines and Met., Univ. of Missouri, Nov., 1917. 48 pages.

A FULLER account of work the chief results of which have been published previously (see this J., 1918, 93 A, 153 A).

Potash recovery. Bradley. See VII.

PATENTS.

Chromium; Depositing — upon metals, particularly iron, chemically. E. E. Burnett, Hayes Town, Middlesex. Eng. Pat. 118,182, Oct. 4, 1917. (Appl. No. 14,336 of 1917.)

IRON or steel may be rendered rust-proof by subjecting the cleaned and grease-free metal to the action of a heated solution of chromium phosphate, preferably containing an excess of phosphoric acid. The solution may be prepared by the action of a 1 to 2% solution of phosphoric acid on chromite or chrome ore.—C. A. K.

Steel; Method of converting iron ores directly into — H. A. Greaves and H. Etchells, Sheffield. Eng. Pat. 118,647, June 12, 1917. (Appl. No. 8366 of 1917.)

A ROTARY inclined tube furnace is arranged in combination with an electric smelting furnace so that the tube furnace discharges into a hopper or shoot, which in turn discharges through the crown of the electric furnace. Connections between the various parts are flexibly luted to provide gas-tight joints, whilst allowing the ordinary manipulation of the furnace. The electric furnace is first charged with ore mixed with powdered carbon and the charge melted, the gases given off during this process passing through powdered or granulated ore in the tube furnace in which partial reduction of the ore takes place. The ore thus enters the electric furnace in a heated and partially reduced condition and powdered carbon is added to effect full reduction, after which refining operations are completed. Owing to the intermittent operation of one furnace it is advisable that two or more refining furnaces should be fed from one tube furnace.—C. A. K.

Case-hardening. A. E. Bamfield, Bristol. Eng. Pat. 118,983, Feb. 18, 1918. (Appl. No. 2823 of 1918.)

TO prevent the localised penetration of carbon during case-hardening of steel articles, the cleaned steel is coated with a plastic paste composed of 50% of sodium silicate, 25% of china clay, 18½% of amorphous silica, and 6¼% of fine silver sand. An impervious coating is formed during the heating. The paste may be similarly applied to prevent decarburisation during annealing.—C. A. K.

Pig-iron; Method of producing — F. H. Croekard, Birmingham, Ala. U.S. Pat. 1,274,245, July 30, 1918. Date of appl., Apr. 2, 1917.

PIG-IRON low in phosphorus is obtained by smelting steel scrap with suitable quantities of coke and fluxes in a blast furnace.—W. R. S.

Ferro-silicide; Manufacture of shaped castings of —. N. G. Pelinot, Assignor to United States Alloys Corporation, New York. U.S. Pat. 1,274,360, July 30, 1918. Date of appl., Dec. 19, 1917.

FERROUS and siliceous materials are heated in an electric furnace with carbonaceous material in such proportions as to obtain ferrosilicon containing 10–16% Si. The molten alloy is poured into a shaped mould, or first into a mixer until sufficient material has been obtained for the casting.

—W. R. S.

Iron; Process of electrolytically producing —. A. T. C. Estelle, Hagen, Germany, Assignor to M. F. Wijkstrom, Stockholm, Sweden. U.S. Pat. 1,275,161, Aug. 6, 1918. Date of appl., Nov. 22, 1916.

IRON is produced electrolytically by treating compounds, such as oxides, of iron with caustic alkali or alkali carbonate at high temperatures, and subjecting a slime of the caustic alkali solution and the iron compounds to electrolysis. By mixing with the iron compounds, compounds of other metals, such as cadmium, which can be precipitated under the prescribed conditions, iron alloys may be obtained.—B. N.

Etching steel or other like plates; Method of —. W. S. Eaton, Sag Harbor, N.Y. U.S. Pat. 1,275,408, Aug. 13, 1918. Date of appl., Nov. 28, 1916.

THE plate, with some parts protected by a resist, is submerged in an electrolytic bath composed of a chloride solution of such strength that it has little or no corrosive action on the metal. The plate forms the anode in the electrolytic cell, and the voltage of the current used is below the decomposition voltage of the electrolyte, but sufficiently high to dissociate the chlorine from the solution, the etching being done by the gas in a nascent state.

—B. N.

Steel; Process for hardening —. J. W. Gilbert, Assignor to D. H. Parker, Windsor, Vt. U.S. Pat. 1,275,242, Aug. 13, 1918. Date of appl., May 8, 1916.

HIGH-SPEED steel is heated slowly to about 700° F. (370° C.), then more rapidly to 1500° F. (815° C.), and at a still more rapid rate to a maximum of 2000°–2500° F. (1090°–1370° C.). The steel is withdrawn and cooled in a metal bath to between 700° and 1500° F. (370°–815° C.), and finally cooled in air to below 200° F. (93° C.).—C. A. K.

Armour-plates; Method of and apparatus for casting —. L. Gathmann, Washington, D.C.; O. G. Foley, administratrix. U.S. Pat. 1,276,517, Aug. 20, 1918. Date of appl., Feb. 15, 1916.

MOLTEN metal cast in a mould is caused to cool more regularly by passing a cooling medium horizontally through the lower portion of the metal, and a heating medium through the upper portion. A metallic mould built in sections is provided with a number of horizontal hollow cores supported by the sections, by means of which the heating and cooling are effected.—C. A. K.

Zinc; Electrolytical production of —. G. H. Clevenger, Palo Alto, Cal., U.S.A. Eng. Pat. 115,847, May 7, 1918. (Appl. No. 7667 of 1918.) Under Int. Conv., May 7, 1917.

IN the electrodeposition of zinc from a zinc sulphate electrolyte, metals, such as cobalt, are removed

from the electrolyte by precipitation with nitroso- β -naphthol, the latter being formed within the electrolyte by the interaction of finely-divided β -naphthol, an acid, and a soluble nitrite, such as sodium nitrite. The electrolyte is subsequently treated with zinc dust to decompose the nitrite or nitrate.

—B. N.

Zinc; Process of treating —. C. A. H. de Saulles, New York. U.S. Pat. 1,274,249, July 30, 1918. Date of appl., Nov. 3, 1915.

ZINC containing lead is first melted to allow a large proportion of the lead to separate by gravity. The zinc is then distilled, and the distillate kept in a molten condition until a large quantity has collected.—W. R. S.

Smelting furnaces and the like. J. Gaunt, D. Brookfield, and J. Tylor and Sons, Ltd., London. Eng. Pat. 118,750, Nov. 24, 1917. (Appl. No. 17,367 of 1917.)

A HOPPER lined with refractory material and having a hinged cover is attached to a smelting furnace so that the products of combustion pass through and preheat a charge in the hopper, afterwards escaping through a side flue. The base of the hopper is suitably shaped to deflect the hot gases into the preheater. Attachment to the furnace may be made by means of a loose grooved ring and the whole may be lifted away to give access to the furnace.

—C. A. K.

Roasting furnaces; Mechanical —. A. Ramen, Helsingborg, Sweden. Eng. Pat. 118,812, Apr. 12, 1918. (Appl. No. 6271 of 1918.)

THE revolving shaft of a mechanical roasting furnace contains a movable and detachable water-supply pipe for each stirring-arm; the pipe at its outlet end is connected to a hollow valve body which corresponds to a valve seat surrounding the water inlet of the circulating channel of the arm, and is adapted to be tightly pressed against the seat. The member for pressing the valve body against its seat may be situated within the furnace shaft or the stirring-arm. The valve body may be mounted on an inner lining, the interior of which communicates with the water supply; the lining has an opening communicating with an outlet in the valve body.

—W. R. S.

Furnaces for roasting blende, pyrites, or other materials; Mechanical —. H. C. Bingham, London. Eng. Pat. 118,940, Nov. 13, 1917. (Appl. No. 16,636 of 1917.)

IN a roasting furnace of the superimposed hearth type, the upper surfaces of the hearths are inclined, so that the flow of material under the action of the rabbles is constantly opposed by the inclination of the hearth to a greater or lesser extent according to the degree of mobility of the material treated. In a modification some of the hearths are so inclined, the others being horizontal.—C. A. K.

Furnace; Electric — [for sintering tungsten]. C. A. Pfanstiehl, Waukegan, Ill., Assignor to Pfanstiehl Co., Inc., North Chicago, Ill. U.S. Pat. 1,273,920, July 30, 1918. Date of appl., Nov. 19, 1914.

A FURNACE for sintering ingots of compressed metallic tungsten powder at or near its fusing temperature comprises a refractory tube forming a heating chamber, with a pair of water-cooled terminal blocks at the ends. Two parallel rods of ductile metallic tungsten of fibrous structure are interposed between the terminals, so as to form a cradle for supporting and maintaining intimate

contact with the ingot to be sintered. An atmosphere of hydrogen is maintained within the chamber during the sintering operation, and an electric current is passed from one block to the other through the cradle, so as to raise the temperature of the latter to the fusing point of metallic tungsten.—B. N.

Alloys, and process of making the same. F. Milliken, New York. Eng. Pat. 118,825, May 17, 1918. (Appl. No. 8289 of 1918.)

AN alloy containing Cu 60–70, Ni 6–9, Fe 4–6, Zn 12–16, Pb 2–3%, and a trace of phosphorus, is claimed to be immune to corrosion by sulphuric acid.—W. R. S.

Alloy for resistance elements, etc. W. B. Driver, East Orange, N.J. U.S. Pat. 1,274,250, July 30, 1918. Date of appl., Jan. 2, 1914.

A DUCTILE and malleable alloy of high specific electric resistance contains at least 1% Ti and over 20% Ni. Some examples are given in the following table:—

Ni	Cr	Ti	Fe	Mn	Resistance, microhms per cm. cube
%	%	%	%	%	
75	—	6	19	—	77
68	15	4	11	2	117

—W. R. S.

Roasting ore; Process for —. C. H. Fulton, Cleveland, Ohio, Assignor to Metallurgical Laboratories, Inc., Chicago, Ill. U.S. Pat. 1,273,844, July 30, 1918. Date of appl., Aug. 19, 1916.

FINELY divided ore is suspended in a slow current of preheated air and caused to pass into a chamber which is heated to a temperature above the ignition point of the ore. The desulphurised ore is then separated from the exit gases.—C. A. K.

Cleaning metal articles; Method of —. C. B. Morey and C. J. Huber, Assignors to Larkin Co., Buffalo, N.Y. U.S. Pat. 1,274,186, July 30, 1918. Date of appl., June 23, 1917.

ARTICLES of gold, silver, etc., are cleaned by immersion in a dilute acid solution of an electrolyte, the metal article being in contact with a more electro-positive metal (e.g. zinc).—C. A. K.

Copper; Method of producing commercially pure —. C. S. Bradley, New York. U.S. Pat. 1,275,374, Aug. 13, 1918. Date of appl., Oct. 25, 1913. Renewed Dec. 20, 1917.

A CHLORINE compound of copper (e.g. the trioxychloride $\text{CuCl}_2 \cdot 3\text{CuO}$) is reduced at a red heat by means of carbon and a base (e.g. lime), the chloride of which is fusible but non-volatile at the melting point of copper. The finely divided reduced copper is melted in the fused chloride bath and separated.

—C. A. K.

Solutions [electrolytes from copper refining]; Process of treating foul —. F. T. Smith, Jamaica Plain, Mass. U.S. Pat. 1,276,130, Aug. 20, 1918. Date of appl., Apr. 2, 1915.

AN impure electrolyte composed of a solution of acid and salts is electrolysed in the anode chamber of an electrolytic cell containing a soluble anode, whilst an acidified solution of pure copper sulphate flows through the cathode chamber. An oxidising agent and a basic precipitant for iron are added to the anode chamber, and the solution is further treated to remove other impurities and leave only pure copper sulphate which is passed to the cathode chamber.—J. H. J.

Metals; Extracting — from ores. C. Biesel, El Paso, Texas. U.S. Pat. 1,276,162, Aug. 20, 1918. Date of appl., Jan. 9, 1917.

ORE is crushed in the presence of a solvent, and the solution separated, the ore being subjected to further grinding with a fresh portion of the solvent. The process is repeated in sequence as great a number of times as required, the impoverished ore being treated with new solvent in each grinding operation.—C. A. K.

Ores; Process of concentrating —. R. G. Hall, St. Louis, Mo. U.S. Pat. 1,276,058, Aug. 20, 1918. Date of appl., Sep. 15, 1916.

ORES containing zinc, lead, and other metals are partially roasted, and mixed with a reducing agent and a proportion of sulphur (as sulphide) sufficient to form a matte with the more valuable metals. The charge is heated in a reverberatory furnace, with volatilisation of the zinc and lead, the other metals such as copper, silver, and gold being obtained as a matte, and waste silicious materials being eliminated in the form of slag.—C. A. K.

Steel and other metals and alloys; Apparatus for the quenching, hardening, tempering, or like heat treatment of —. H. C. Dickson, Quinton, Eng. Pat. 118,954, Dec. 1, 1917. (Appl. No. 17,793 of 1917.)

Iron ore; Method of treating —. F. A. Eustis, Milton, Mass., U.S.A. Eng. Pat. 112,615, Oct. 1, 1917. (Appl. No. 14,132 of 1917.) Under Int. Conv., Jan. 12, 1917.

SEE U.S. Pat. 1,237,765 of 1917; this J., 1917, 1099.

Steel; Method of and means for annealing [high-speed] —. J. G. R. Munday, Kingston-upon-Hull. U.S. Pat. 1,277,244, Aug. 27, 1918. Date of appl., Aug. 6, 1917.

SEE Eng. Pat. 106,624 of 1916; this J., 1917, 886.

Alloys. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 118,947, Nov. 20, 1917. (Appl. No. 17,095 of 1917.)

SEE U.S. Pat. 1,273,762 of 1918; this J., 1918, 591 A.

Flux for use in brazing cast-iron and other metals. A. Figgins, Richmond, and J. H. Nathan, St. Kilda, Victoria, Australia. U.S. Pat. 1,275,412, Aug. 13, 1918. Date of appl., Jan. 18, 1917.

SEE Eng. Pat. 112,500 of 1917; this J., 1918, 127 A.

XI.—ELECTRO-CHEMISTRY.

Sodamide and potassamide; Electrolysis of molten —. L. Wöhler and F. Stang-Lund. *Z. Elektrochem.*, 1918, 24, 261—270.

MOLTEN sodamide and potassamide on electrolysis produce as anode products ammonia and nitrogen but no hydrazine as was expected. These substances melt at 210° and 338° C. respectively, these values being about 60° higher than the values given by Titherley. In the analysis of the amides it is advantageous to moisten with alcohol before adding water to produce ammonia. (See also *J. Chem. Soc.*, Nov., 1918.)—J. F. S.

High pressures; Production of — by electrolysis. K. Wilkens. *Chem.-Zeit.*, 1918, 42, 428.

If water is electrolysed in a completely filled vessel, the gases produced can only occupy the space of the decomposed water, that is, in 1 ampère-hour, 624 c.c. of gases must occupy a volume of 0.2354 c.c. and will be under a pressure of 1860 atmospheres. When only nine-tenths of the volume of the vessel is filled with water and the remaining one-tenth occupied by air, the pressure after electrolysis for 1 hr. (with 1 amp.) will be 7 atmospheres; after 19 hrs., 61; after 50 hrs., 269; and after 1000 hrs., 1433 atmospheres.—W. P. S.

Insulating materials; Electrical —. Bültemann. *Verbandsmitt. Ver. Dresdner Bez.-Ver. Ing. und Dresdner Elektrotechn. Ver.* (Reprint.) *Z. angew. Chem.*, 1918, 31, Ref., 233—234.

MARBLE or slate when used as insulating plates in electric installations must be polished and impregnated or coated with an enamel varnish. Mica has excellent insulating properties, plates of 1 mm. resisting 40,000 volts or more. Micanite, megotale, micarta, etc., are commercial products prepared from mica flakes and a binding agent such as shellac varnish, etc. Experiments made in America with wood impregnated with asphalt, linseed oil, or paraffin wax have not given satisfactory results. Vulcanite is a good insulator, and when compressed with asbestos fibre forms the so-called "vulcan asbestos." Ebonite formed by vulcanising gutta-percha is not equal to hard rubber (vulcanite) as regards its resistance to temperature. "Vulcan fibre" is a trustworthy insulator when in the dry condition. Cellon varnishes are suitable for coating electric wires, etc. The hard cellon preparations have an insulation resistance of about 10,000 megohms, and plates 1 mm. thick resist up to 30,000 volts. Good insulating powers are also shown by monite, a cellulose product of the viscose type. Other technical products of importance are the phenolic resins, "bakelite," "faturane," and "eswelite." "Faturane" has an insulating resistance of more than 100,000 megohms, and in plates 3 mm. thick resists 25,000—30,000 volts (alternating current). "Eswelite" (sp.gr. 1.2) has an insulating resistance of 8,000,000 megohms. Numerous insulating materials such as "eshalite," "ambroine," "tenacite," "agalite," "australite," "fetonite," etc., are composed of asbestos with binding agents.

PATENTS.

Electrodes for electric furnaces and like purposes. W. B. Hamilton, H. A. Blackwell, and W. L. Turner. Liverpool. Eng. Pat. 118,690, Sep. 14, 1917. (Appl. No. 13,172 of 1917.)

AN electrode is formed of a hollow container of refractory material, with a tapered block of carbon at, and projecting from, one end. A metallic presser device at the other end is adapted to compress and consolidate a granular or finely-divided mass of graphite within the hollow container, which is supported and reinforced by metal rods. The body of the electrode is rigidly held from a carrier, and the metal presser device is supported in a separate carrier in which it is adjustable. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 7001 of 1905; this *J.*, 1906, 433.)—B. N.

Electrodes; Manufacture of carbon —. B. E. D. Kilburn, London. From Det Norske Aktieselskab for Elektrokemisk Industri Norske Industrihøypotekbank, Christiania, Norway. Eng. Pat. 119,018, Jan. 9, 1918. (Appl. No. 9285 of 1918.)

CARBONACEOUS material is pressed or stamped around a metallic core, and is then baked, first by the heat produced by current passing through the core, and then by current passing through the carbonaceous material of the electrode itself.

—B. N.

Depolarising material; Volume-stable manganese —. *Void-filled depolarising mass. Non-conducting manganese depolarising electrode.* C. Ellis, Montclair, N.J., Assignor to National Carbon Co., Inc., Long Island City, N.Y. U.S. Pats. (A) 1,272,405, (B) 1,272,406, (C) 1,272,407, July 16, 1918. Dates of appl., (A) Oct. 23, (B and C) Oct. 18, 1915.

(A) NORMAL manganese dioxide is heated in an atmosphere of oxygen to a sintering temperature for the preparation of a depolariser for dry batteries of the Leclanché type. (B) The depolariser is in the form of a moulded mass of finely-divided psilomelane, the particles of which are of different sizes, so that the voids are substantially filled. (C) The depolarising electrode is formed of a rod-shaped carbon structure, supporting an annular compressed mass of graphite, and artificial substantially non-conducting manganese dioxide in a slight state of hydration obtained by dehydrating hydrated manganese dioxide up to the point where it becomes substantially non-conducting to electric current, i.e., when it contains 1 mol. H₂O to 8 mols. MnO₂.—B. N.

Depolarising material; Preparation of higher oxide of manganese —. C. Ellis and A. A. Wells, Montclair, N.J., Assignors to National Carbon Co., Long Island City, N.Y. U.S. Pat. 1,275,666, Aug. 13, 1918. Date of appl., Dec. 6, 1916.

THE precipitate produced by mixing solutions of sodium carbonate and a manganous salt is dried without washing and then ground and exposed to a current of air and water vapour at about 200° C. The resulting manganese dioxide is then washed and dried.—W. H. C.

Plastic [insulating] composition and process of making the same. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,274,728, Aug. 6, 1918. Date of appl., July 3, 1914.

TANNINS and tannin-containing materials form efficient binding agents for the manufacture of insulating compositions. Lime, magnesia, or other compounds which form insoluble products with

tannins, may be used as fillers. The waste products of the tanning industry known as phlobaphenes or "reds" may be utilised in this way. With tannins as binding material, moreover, compact, hard moulded products may be prepared from ground cork.

(A) *Furnace; Electric* —. (B) *Furnace for chemical reactions*. (C) *Electric furnace*. (D) *Process of producing aluminium nitride*. (E) *Electric furnace*. M. Shoeld, Assignor to Armour Fertilizer Works, Chicago, Ill. U.S. Pat. (A) 1,274,794, (B) 1,274,795, (C) 1,274,796, (D) 1,274,797, (E) 1,274,798, Aug. 6, 1918. Dates of appl., (A, B, C, D) Jan. 28, 1918, (E) Mar. 6, 1918.

(A) An electric furnace comprises a heating chamber, with an electrically-conductive lining, an outer horizontal ring electrode, and a central vertical electrode, which projects down into the plane of the ring electrode. The material to be treated is fed downwards between the electrodes, and a current of gas is directed upwards through the material. The latter is simultaneously subjected to the action of the gas and the heating effect of the current, the electrodes being of greater electrical conductivity than the lining. (B) The material to be treated is placed in carriers with perforated bottoms, which are caused to slide through an inclined chamber, heated by suitable means, and having a perforated floor. Gas, which has been preheated by the treated material, is passed through the chamber and material, and the gas escaping through the perforations of the carriers and chamber bottom, is used to preheat the material before it enters the furnace. (C) An electric furnace having a conduit for the passage of the material to be treated, is provided with means for heating an intermediate portion only of the conduit. For example, one or more electrodes are arranged in contact with the external portion of the conduit, and form one or more arcs with other adjacent electrodes. (D) A nitrogen-containing gas is uniformly distributed through, and made to travel in the opposite direction to, a body of briquettes, composed of finely-divided carbon, alumina, and a binder. An intermediate zone of the mixture is simultaneously uniformly heated to a temperature of 1800° to 2000° C. by an electric current, e.g., in a furnace of the type described under (A), and the gas is preheated by the treated briquettes, whilst the hot escaping gas is employed to preheat the briquettes as they approach the heating zone. (E) An arc is formed between vertical electrodes, in a heating chamber, lined with carbon, provided with an inclined passage for conveying the material to be treated, and for passing the gas in a direction opposite to the travel of the material. The passage is "off-set" practically vertically, substantially at a point beneath the arc, so that the direction of travel of the material is changed whilst at its highest temperature.—B. N.

Furnace; Electrical induction —. O. C. Böckman, Notodden, Norway. U.S. Pat. 1,275,206, Aug. 13, 1918. Date of appl., May 3, 1918.

THE furnace is provided with an induction coil, and a core forming a closed path for the magnetic flux created by the coil. A pivoted member, forming an extension of the core outside the furnace, is arranged in parallel with the ordinary path of magnetic flux, and the path of magnetic flux in the extension may be closed or interrupted, with the object of regulating the magnetic flux in the main core, thus permitting regulation of the furnace temperature independent of the current and magnetic coils.—B. N.

Electric furnace. U.S. Pat. 1,273,920. See X.

Etching. U.S. Pat. 1,275,408. See X.

Treating foul electrolytes. U.S. Pat. 1,276,130. See X.

XII.—FATS; OILS; WAXES.

Saponification of citric acid esters and of glycerides; Alkaline —. J. Pinnow. Z. Elektrochem., 1918, 24, 270–278.

COTTONSEED oil, when treated with alcoholic potash, is converted to the extent of 75% into ethyl esters, whilst a small quantity is directly hydrolysed. The glycerol content of cottonseed oil can be estimated by weighing and the use of an analytical correction. Dilute acids hydrolyse asymmetrical diethyl citrate in two ways with the production of the two monoethyl esters.—J. F. S.

Crismer test. Stewart. See XIXA.

PATENTS.

Oils, wax, rosin and materials of a like nature; Extraction of — from bone charcoal or other substances containing the same. J. MacGregor, Glasgow, and G. Scott and Son (London), Ltd., London. Eng. Pat. 118,461, Aug. 30, 1917. (Appl. No. 12,472 of 1917.)

THE material, e.g., bone charcoal or fullers' earth, or the like, is emulsified with water, and the emulsion treated in successive baths of an immiscible solvent lighter than water. After subsidence of the solid particles the supernatant layer of solvent and dissolved oil or the like is decanted.—C. A. M.

Fats, oils, waxes, and the like; Process of and apparatus for hydrogenating —. J. B. Walker, Austin, Tex. U.S. Pat. 1,276,290, Aug. 20, 1918. Date of appl., Jan. 6, 1917.

LIQUEFIED fats, etc., are heated and hydrogenated in the presence of a finely divided catalyst. The escaping hydrogen is conducted through a body of coarse catalytic material, whilst simultaneously portions of the oil previously withdrawn from that already treated are sprayed on to this material and allowed to percolate through it into the main body of the oil. Apparatus for this process comprises a closed vessel divided into an upper and a lower compartment by means of a porous diaphragm of coarse catalytic material. The lower compartment contains trays adapted to support catalytic material, whilst the upper compartment contains a fluid-driven motor and a gas pump connected with a gas-circulating conduit and condenser outside the receptacle.—C. A. M.

Hydrocarbons, their homologues and substitution products; Process of preparing stable aqueous solutions of —. Schülke und Mayr, and H. Kantorowicz, Hamburg. Ger. Pat. 206,059, July 7, 1912.

SMALL amounts of neutral alkali salts of inorganic or organic acids (e.g., sulphites, oxalates, phosphates, sodium chloride, or potassium cyanide) are added to rosin soaps or sulphonated soaps, to increase by five or six fold their power of rendering soluble in water hydrocarbons (with the exception of halogen derivatives of hydrocarbons of the ethylene series), mineral oils, terpenes, and especially essential oils.—C. A. M.

Fats and oils; Method of refining —. S. Morgenstern, Leipzig, Germany. U.S. Pat. 1,275,289, Aug. 13, 1918. Date of appl., July 3, 1914.

SEE Fr. Pat. 473,761 of 1911; this J., 1915, 804.

Hydrogenation of fats and oils. J. Dewar, London, and A. Liebmann, Weybridge, Assignors to The Proctor and Gamble Co., Cincinnati, Ohio. U.S. Pat. 1,275,405, Aug. 13, 1918. Date of appl., June 2, 1914.

SEE Eng. Pats. 12,981 and 12,982 of 1913; this J., 1914, 797.

Oils; Process of obtaining —. J. Stewart, Philadelphia, Pa., Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,276,822, Aug. 27, 1918. Date of appl., Oct. 27, 1915.

SEE Eng. Pat. 101,959 of 1916; this J., 1917, 557.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Constituents of —. H. Constituents of Sumatra gum benzoin. H. Lieb and A. Zinke. Monatsh. Chem., 1918, 39, 219–230. (See also this J., 1918, 520 A.)

CONTRARY to the opinion of Lüdy (this J., 1893, 946) the resinol obtainable from Siamese gum benzoin is not identical with that from Sumatra gum benzoin. Whereas the former resin is only partially soluble in hot dilute sodium hydroxide solution, the latter dissolves entirely, although on boiling the solution for an hour colourless needles separate of a levo-rotatory sodium salt of a previously unisolated *l*-benzoresinol, m.pt. 339°–341° C., $[\alpha]_D^{25} = -12.88$, probably of the composition $C_{20}H_{14}O_4$. On the addition of a little ether to the alkaline mother liquor there is obtained a deposit of the sodium salt of a dextro-rotatory resinol, $C_{20}H_{14}O_4 \cdot H_2O$, crystallising in needles m.pt. 298°–299° C., $[\alpha]_D^{25} = +51.60$, to which the name *d*-sumaresinol is given; it is soluble in aqueous ammonia. *d*-Sumaresinol is isomeric with siaresinol. The benzoresinol described by Lüdy as obtainable from Sumatra gum benzoin was probably merely a mixture of *d*-sumaresinol with a small proportion of *l*-benzoresinol.—D. F. T.

PATENTS.

Paint and method of making same. F. W. Sperr, jun., Oakmont, Assignor to H. Koppers Co., Pittsburgh, Pa. U.S. Pat. 1,275,778, Aug. 13, 1918. Date of appl., Jan. 18, 1917.

MELTEE pitch from tar containing not more than 6% of free carbon is mixed with solvent naphtha at a temperature between 100° and 200° C., the proportion of the naphtha being insufficient to produce "precipitation" of the pitch. The resulting colloidal solution dries readily to form a smooth glossy film.—C. A. M.

Coating composition. C. P. Townsend, Washington, D.C., Assignor to General Bakelite Co., New York. U.S. Pat. 1,273,954, July 30, 1918. Date of appl., Dec. 18, 1914.

A BASE for antifouling paints and varnishes is made by incorporating or chemically combining a salt of copper or other toxic substance with a condensation product of phenol and formaldehyde, or other phenolic condensation product which becomes insoluble and infusible when heated.—C. A. M.

Phenol-aldehyde condensation product. T. S. Wennagel, Alt-Rahstedt, Germany, Assignor to Naaml. Vennoots. Hollandsche Proteïne Maatschappij, Amsterdam, Holland. U.S. Pat. 1,273,967, July 30, 1918. Date of appl., Jan. 22, 1917.

NEUTRAL alkali salts of aromatic hydroxy-acids which are not hydrolytically dissociated are used as condensing agents in the preparation of phenol-aldehyde condensation products.—C. A. M.

Paint and varnish; Composition for removing —. C. McAdam, Chicago, Ill., Assignor to Chadeloid Chemical Co., New York. U.S. Pat. 1,274,430, Aug. 6, 1918. Date of appl., June 14, 1915.

CRESOL or other relatively slowly volatile hydroxy derivative of benzol, to act as a varnish-penetrating agent, is emulsified with a loosening agent (grain alcohol, acetone, celluloid, and gum camphor), and a wax (spermaceti).—C. A. M.

Finishing, cleaning, or polishing composition and process of making same. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 1,276,481, Aug. 20, 1918. Date of appl., May 20, 1918.

A COMPOSITION for polishing, finishing, etc., is prepared by mixing naphthalene tetrachloride or other halogen compound of naphthalene with a mineral hydrocarbon, and in particular with petroleum the sp. gr. of which is too high for a lamp oil and too low for lubricating purposes under ordinary atmospheric conditions.—C. A. M.

Impregnating composition and method of making same. W. V. Lander, Newton, Mass., Assignor to General Indurating Corporation. U.S. Pat. 1,277,322, Aug. 27, 1918. Date of appl., Dec. 20, 1916.

A COMPOSITION for impregnating porous or bibulous materials consists of a solution of petroleum residue and colophony in gasoline.

Resins; Manufacture of — from benzol plant residues. H. Koppers Co., Pittsburgh, Assignees of M. Darrin, Wilkinsburg, Pa., U.S.A. Eng. Pat. 112,419, Oct. 1, 1917. (Appl. No. 14,166 of 1917.) Under Int. Conv., Dec. 30, 1916.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Influence of opening a tapping cut and of pollarding on latex and —. O. de Vries, Communications of the Central Rubber Stat., Buitenzorg, Java, 1918, 2, 241–255.

WHEN the tapping cut was freshly opened, the amount of latex increased during the first few days as the cut was brought to the usual depth, and reached a maximum of nearly 80 c.c. after a week, subsequently decreasing to 60 c.c. after one month and 509 c.c. after two months; the rubber content decreased from 44.0% on the first day to

35.0% after one week and attained a constant value of 25–26% after the second week, whilst the specific gravity increased from 0.9689 to 0.9920, or from 0.9895 to 0.9950 if compared after dilution to a 15% rubber content. During these changes the tensile strength of the rubber remained constant, but the rate of vulcanisation gradually increased from a period of 145 minutes to 100 minutes, the "slope" increasing from 32.5 to 37; constancy was attained in about four weeks. Pollarding at a height of 3 m. from the ground caused a sudden alteration in rubber content of latex from 26% to 21% and in sp. gr. from 0.9910 to 0.9960 for undiluted latex or 0.9946 to 0.9970 for latex diluted to 15% rubber content, constancy being attained in a few days. The alteration in the qualities of the rubber was within the usual limits of variation for plantation rubber, a slight increase in rate of vulcanisation and a possible slight reduction in tensile strength being observed. Within a month after pollarding the latex production had diminished to one-third.—D. F. T.

Rubber; Differences in weight in the preparation of sheet and crêpe —. O. de Vries and H. J. Hellendoorn. Communications of the Central Rubber Stat., Buitenzorg, Java, 1918, 2, 361–400.

THE serum from rubber latex, when slightly milky, does not contain rubber but only proteins and the danger of loss of rubber in milky serum is exaggerated; indeed when a small percentage of rubber is lost in the serum, the value of the rubber lost is often less than that of the additional acetic acid which would be necessary to produce a clear serum. The chief cause of difference in weight of rubber produced is the variation in the content of serum substances. Excluding matured slab rubber, the difference in the weight of crêpe rubber produced in various ways may amount to 1%, whilst for sheet rubber it may be 3%. With modern methods, involving standardised procedure such as a standard concentration of rubber in latex before coagulation, and rolling on the day after coagulation, the difference generally does not exceed $\pm 0.5\%$. The moisture content of rubber is higher the greater its relative weight, i.e., the greater its content of serum substances. By diluting the latex before coagulation or especially by soaking the sheets in water, the proportion of serum substances in the rubber is diminished, and the subsequent air-dried rubber shows a decreased moisture content.

—D. F. T.

[*Rubber*] *coagulum; Maturing of* —. O. de Vries. Communications of the Central Rubber Stat., Buitenzorg, Java, 1918, 2, 213–240.

THE results of Eaton and his co-workers (this J., 1916, 715, 1046; 1917, 1217) and of Campbell (this J., 1917, 604) as to the increased rate of vulcanisation of matured or "slab" rubber are confirmed, but the actual rate is found to be far from uniform for matured rubber prepared on different estates or under different conditions. The tensile strength is only slightly superior to that of sheet rubber, but the great superiority of sheet to ordinary crêpe in strength as reported by Eaton appears to be out of accord with the observations of other workers. Whether the greater strength of vulcanised matured slab rubber is an intrinsic characteristic of the rubber or is merely due to the shorter period of heating necessary for vulcanisation remains yet to be decided. The "slope" (Schidrowitz, this J., 1915, 842; Whitby, this J., 1916, 495) is smaller and therefore the resistance to stretching at greater elongations is better for slab rubber and the viscosity of the solutions is higher; on the other hand, the hardening of the coagulum and consequent difficulty in rolling, the slow dry-

ing of the crêpe mass, and the frequent poor colour are disadvantages. During maturing of the coagulum the decomposition of serum substances causes a loss in weight of 2–2½%. Natural variation in the composition of the latex has a marked influence on the rate of vulcanisation of the matured rubber, and dilution of the latex also gives rise to a more slowly vulcanising rubber with a decreased "slope," but unaltered tensile strength and viscosity. If the coagulum is kept under water, the resulting rubber has approximately the same rate of vulcanisation as ordinary crêpe, whilst soaking in water after maturing for several days in the air also causes a reduction in the rate, the effect in both cases being probably due to the extraction of serum substances or decomposition products of these. If freshly rolled crêpe is kept in water for several days, it undergoes alteration comparable with the effect of maturing, possibly because the harder crêpe does not yield its serum substances so readily to the water. The addition of sodium bisulphite to latex retards the changes caused by maturing, but even with 1 grm. per litre of latex the effect is only small.—D. F. T.

Vulcanisation without sulphur by Ostromyslenski's method. E. Bunschoten. Kolloid. Zeits., 1918, 23, 25–31.

IN his experiments on the vulcanisation of rubber by means of such substances as mono-, di-, and trinitrobenzene, Ostromyslenski made no quantitative measurements of the physical properties of his products. In the experiments here reported the progress of vulcanisation was followed by breaking-stress and extension tests. Preliminary experiments in which raw rubber was heated with nitrobenzene and *m*-dinitrobenzene at 147° C. for 30, 60, or 90 minutes gave negative results, and even in presence of such organic accelerators as "acceleren" (*p*-nitrosodimethylaniline) and "vulcazite" (a condensation product of ammonia and acetaldehyde) no vulcanisation occurred. Different metallic oxides, however, were found to act as catalysts towards rubber and nitro- or *m*-dinitrobenzene, and in all the subsequent experiments lead oxide was used. Experiments were made on two varieties of rubber, a quick vulcanising smoked sheet with a vulcanisation coefficient of 4.5, and a slow vulcanising first latex crêpe with a coefficient of 2.6. Nitrobenzene was found to have poor vulcanising properties, *m*-dinitrobenzene giving much better results. In both cases the smoked sheet was vulcanised by the organic agent more quickly than the crêpe, just as when sulphur is used. There are exceptions, however, cases being known in which the sample which is vulcanised the more rapidly by sulphur is affected less readily by dinitrobenzene. The time factor is important, for if heating is continued beyond a certain length of time the physical properties of the sample deteriorate. Thus 100 parts of smoked sheet heated with 8 parts of lead oxide and 4 parts of *m*-dinitrobenzene at 147° C. showed the best results after 10–15 minutes. The velocity of vulcanisation is also increased by increasing the proportion of catalyst and of vulcanising agent within certain limits. Between 137° and 157° C. the velocity of the reaction increases markedly with rising temperature. The quality of the rubber vulcanised with *m*-dinitrobenzene deteriorates rapidly; after a month a sample had become quite soft, although it was still insoluble in benzene. The samples also became gradually coated with crystals of dinitrobenzene. Attempts to prepare hard rubber by prolonged heating of raw rubber with lead oxide and dinitrobenzene failed. A soft leather-like substance was obtained which gradually extruded crystals of *m*-nitraniline. Attempts were made to vulcanise rubber by heating with inorganic

oxidising agents such as arsenic acid, potassium persulphate, bleaching powder, potassium bichromate, permanganate, chlorate, nitrate, and ferricyanide, and manganese dioxide. In each case vulcanisation appeared to commence but the products were unsatisfactory, although better than those obtained by use of mono- or dinitrobenzene without the addition of lead oxide. The addition of *m*-dinitrobenzene to a benzene solution of rubber increases the viscosity of the solution in the dark at ordinary temperatures, and more so at 65° C. Under the influence of light, however, the viscosity rapidly falls. It is concluded that the vulcanising action of dinitrobenzene is due to an acceleration of polymerisation of the rubber. Sulphur acts in the same manner, but at the same time forms a chemical or physical compound.—E. H. R.

PATENT.

Sheet-rubber; Manufacture of — W. Seward. Toronto, Canada. U.S. Pat. 1,274,091, July 30, 1918. Date of appl., Feb. 27, 1918.

A SHEET of dried pure crepe rubber is united, by rolling, with a sheet of washed, dried, and broken down rubber, and the composite sheet is vulcanised. —C. A. M.

XV.—LEATHER; BONE; HORN; GLUE.

Hide-powder; Adsorption by — V. Kubelka. Kolloid. Zeits., 1918, 23, 57–68.

As a result of experiments on the removal of hydrogen chloride from aqueous solution by hide powder, it has been found that the hide substance retains its absorbing capacity unchanged for at least two years when the powder is preserved in a carefully stoppered bottle. The equilibrium between the hide powder and the acid solution is rapidly attained and in the case of pure hydrochloric acid solutions the quantity of acid in the hide is independent of the concentration of the acid in the aqueous solution. For acids of concentration $N/100$ to $N/1$, the quantity of hydrogen chloride fixed by 1 gm. of dry hide powder is found to be 0.739 millimol. In presence of considerable quantities of sodium chloride, hydrogen chloride is removed more easily from the aqueous solution and under these conditions the amount of acid in the hide powder depends on the concentration. From solutions saturated with respect to sodium chloride, the quantity of hydrogen chloride absorbed by 1 gm. of hide powder increases from 0.773 millimol. in the case of 0.008 N acid to 1.655 millimol. in the case of 0.95 N acid. The graphic representation of the actual results suggests that the phenomenon is of complex character in that the absorption curve consists of two distinct branches. The first portion of the curve appears to reach a maximum corresponding with the absorption of 1 gm.-mol. of HCl per 977 grms. of hide powder and it is supposed that this indicates the formation of a definite compound between the hide substance and the acid. The number 977 would thus represent the molecular weight of the hide collagen. The second branch of the absorption curve is of the normal adsorption type and it is inferred that the compound formed is capable of removing further quantities of hydrogen chloride from aqueous solutions containing sodium chloride in virtue of its adsorptive faculty.

—H. M. D.

Gelatin and glue; "Jelly value" of — A. W. Clark and L. DuBois. J. Ind. Eng. Chem., 1918, 10, 707–708.

DEFINITE quantities of the sample (*e.g.*, 1, 2, 3, 4, etc. grms.) are placed in separate test-tubes, 10 c.c. of cold water is added to each, the mixtures are

stirred for some hours, then heated in a boiling water-bath, and afterwards cooled to 0° C., the test-tubes being corked during the cooling. The mixtures are then heated very slowly and observations are made as to whether the contents of a tube are liquid or solid. Usually, it is advisable to make the observation at 10° C. If, for instance, the 3, 4 and 5% mixtures are liquid at 10° C., whilst the 6, 7, and 8% mixtures are solid, the sample is said to have a comparative jelly strength of 6%.—W. P. S.

XVI.—SOILS; FERTILISERS.

Soil classes; Chemical criteria, crop production, and physical classification in two — J. S. Burd. Soil Sci., 1918, 5, 405–419.

DATA are given of the mechanical analyses and chemical analyses by the fusion method, and by extraction with hydrochloric acid (sp. gr. 1.115), and with 1% citric acid respectively, as well as the crop production under controlled conditions, of fourteen soils of which five belong to a single series of one soil type and eight to different series of another type. Seasonal averages of the water extractions of these soils are also given. The results obtained by the water extraction and to a lesser extent by the citric acid extraction method are shown to be in general accord with the soils' crop-producing powers, whereas the complete analysis and hydrochloric acid extraction method are worthless as criteria of present production or probable endurance except in the case of highly silicious soils. The great variations in crop yield and in the analytical figures for the water extractions within a given series and soil type indicate that physical classification into types is inadequate as a means of predicting probable yields or determining fertiliser requirements.—W. G.

Soil; Chemical effects of calcium oxide and calcium carbonate on the —. I. The effect on soil reaction. D. R. Hoagland and A. W. Christie. Soil Sci., 1918, 5, 379–382.

CALCIUM oxide when first added to a soil produces a high concentration of hydroxyl ions, which decreases within a few days and continues to decrease

slowly over a considerable period, but the treated soils still show a greater intensity of alkalinity even after several months as compared with the untreated soils or those to which calcium carbonate has been applied. If a considerable excess of calcium oxide is used, certain soils may maintain such a high hydroxyl ion concentration as practically to inhibit nitrification.—W. G.

Soil; Chemical effects of calcium oxide and calcium carbonate on the —. II. The effect on water-soluble nutrients in soils. A. W. Christie and J. C. Martin. *Soil Sci.*, 1918, 5, 382—392.

SEVEN soils of three different types were examined to find the effect of applications of calcium oxide or carbonate on their water-soluble nutrients. In certain cases the concentration of the soil solution was materially increased by the application of lime, the effect of calcium oxide being more pronounced than that of the carbonate. The effect of lime on soils depends in part upon the previous treatment of the soil, particularly with respect to the concentration of the soil solution. A greater effect was observed in soils recently cropped or having a low initial concentration. The application of lime increased the water-soluble potassium in only two cases and in two soils caused a depression. Soluble magnesium was increased in four soils and decreased in one. Soluble sulphates were increased in four soils, but only two soils showed any significant increase in phosphates.—W. G.

Soils; Partial sterilisation of —. G. Truffaut. *Comptes rend.*, 1918, 167, 433—436.

FIELD experiments with various vegetable crops using carbon bisulphide or calcium sulphide as antiseptics have shown marked increased crop production due to partial sterilisation. The carbon bisulphide was applied at the rate of 500 kilos. per hectare, whilst the most satisfactory rate for calcium sulphide was 250—300 kilos. per hectare applied in February or March. Satisfactory results were also obtained by using a mixture of equal parts by weight of calcium sulphide and naphthalene.

—W. G.

Carbon dioxide; Production of — by moulds inoculated into sterile soil. R. S. Potter and R. S. Snyder. *Soil Sci.*, 1918, 5, 359—377.

TYPICAL soil moulds when inoculated into sterilised soil grew with a vigour equal to or nearly equal to the growth induced by inoculation with the entire soil flora, the vigour of growth being measured by the evolution of carbon dioxide. The presence of calcium carbonate in the soil had no marked effect on the growth of moulds. Two methods of sterilisation were used, namely by heating in an autoclave for three hours at 10 lb. pressure, three times at intervals of 48 hours, which treatment caused an increase in the nitrate, ammonia, and soluble non-protein nitrogen; and by heating in an Arnold steriliser at 99° C. with flowing steam six times for 1½ hours on alternate days, which treatment caused an increase in the ammonia and soluble non-protein nitrogen, but a decrease in the nitrate nitrogen. Moulds caused a decrease in the amount of nitrates in all cases, a decrease in the amount of soluble non-protein nitrogen in nearly every case, and but very little change in the amount of ammonia.

—W. G.

Cane sugar [sucrose]; Inversion of — by soils and allied substances and the nature of soil acidity. F. E. Rice and S. Osugi. *Soil Sci.*, 1918, 5, 323—358.

SOILS of many kinds are capable of inverting sucrose, this power being a property of the mineral

portion as well as of the organic matter of the soil. The effect is undoubtedly due to acid which may be present in one of four forms, viz., a slight amount in certain soils, soluble in the sugar solution; acids ordinarily easily soluble, but in the soil strongly adsorbed on the soil particle surfaces; an insoluble acid, such as silicic acid; acids liberated as a result of the presence in the soil solution of neutral salts of which the bases are more strongly adsorbed than the acids, which latter are thus left free to cause inversion of the sugar. The inversion of sugar by soils is chiefly a property of the insoluble portion, since aqueous extracts had little or no inverting power; the inversion increased with the amount of soil in contact with the sugar solution; long continued and repeated extraction of the soils with water or the sugar solution did not greatly reduce their inverting power. Many soils showed inverting action on sugar in a solution which was neutral or in some cases alkaline after contact with the soil. It was found that silicate minerals in aqueous suspension when submitted to direct electric current acquired inverting power and soils under similar treatment had their soil acidity increased. The authors consider that the measurement of the power of a soil to catalyse the inversion of sucrose is probably the only method which can measure the acidity bound up with the solid phase of the soil.

—W. G.

Fertiliser from the effluent from potassium chloride works. W. Hüttner. *Chem.-Zeit.*, 1918, 42, 434—435.

THE effluent is introduced into a tank containing quicklime, the latter being covered with the liquid; heat is developed and the whole is converted into a powdery mass which consists of magnesium oxide, magnesium and calcium oxychlorides, small quantities of potassium chloride, sodium chloride, calcium sulphate, etc. Its fertilising value depends chiefly on the presence of the magnesium oxide.

Vegetable glue or adhesive. R. W. Tunnell, Philadelphia, Pa. U.S. Pat. 1,275,799, Aug. 13, 1918. Date of appl., Dec. 22, 1917.

A BLEND of high- and low-grade starch of the same kind (*e.g.* 20% of high-grade and 80% of low-grade tapioca) is treated with barium hydroxide, or other alkaline-earth hydroxide, in the proportion of, say, 0.1 to 0.25% of the total weight of starch.—C. A. M.

XVIII.—FERMENTATION INDUSTRIES.

Sisal waste; Utilisation of — for the production of alcohol. Tropical Life, 1917, 13, 155. Bull. Agric. Intell., 1918, 9, 988.

AFTER the fibre has been extracted from sisal there remains much waste. At Yucatan, whence sisal was first exported, alcohol has been made from the waste; the leaves from which the alcohol was made contained 12% of sugar, but sometimes, after a long

dry season, the sugar content reached 14%. Experiments in British East Africa also showed that it is possible to prepare alcohol from sisal; the plants in this case contained 3% of sugar. A yeast was isolated from sisal plants which fermented a dextrose solution but was killed quickly in sisal extract, no doubt owing to the large amounts of organic acids present. After neutralisation with sodium carbonate and the addition of a small quantity of dextrose, the extract did not kill this yeast but no fermentation took place.—W. P. S.

Alcoholic fermentation; Arrest of — in the aldehyde stage. Experimental confirmation of the acetaldehyde pyruvic acid theory. C. Neuberg and E. Reinforth. Biochem. Zeits., 1918, 89, 365–414.

NEUBERG (this J., 1911, 379, 1179; 1913, 803) has shown that yeast can convert pyruvic acid into carbon dioxide and acetaldehyde, and that the latter substance readily undergoes reduction to ethyl alcohol during yeast fermentations. According to the theory set forth by the authors, only one molecule of aldehyde should be formed from one molecule of sugar, the other part of the molecule acting as acceptor for the hydrogen. By fermenting sugar in the presence of disodium sulphite, aldehyde in the amount equivalent to 73.45% of that required by this theory can be isolated. (See also J. Chem. Soc., 1918, i., 517.)—S. B. S.

Catalase of bacteria. Jacoby. Biochem. Zeits., 1918, 89, 350–354.

PROTEUS bacteria were grown on media containing, in addition to inorganic salts, only sodium aspartate and sodium lactate. An active catalase could be obtained from the cultures by precipitation with sodium chloride, or with magnesium or ammonium sulphate. These experiments form part of an attempt to prepare a pure enzyme. (See also J. Chem. Soc., 1918, i., 517.)—S. B. S.

XIXA.—FOODS.

Milk; Certain changes caused by bacteria in some of the nitrogenous constituents of —. G. C. Supplee. J. Dairy Sci., 1917, 1, 313–319. Bull. Agric. Intell., 1918, 9, 990–991.

IN an investigation on changes in the nitrogenous evident, the following species of bacteria were change in the physical appearance of the milk was evident, the following species of bacteria were used:—*B. lactis acidii*, *Mic. albidus*, *Ps. liquefaciens*, *B. lactis viscosus*, *B. mycoides*, "Acid peptoniser" (species unknown), *B. bulgaricum*, *B. coli*

communior, *B. aerogenes*, *B. prodigiosus*, *Ps. pyocaneus*, and *B. subtilis*. All these organisms, except two, caused a decrease in the casein fraction; with some, there was an increase in the albumin fraction, with others a decrease in the albumin fraction and little or no decrease in the casein fraction.—W. P. S.

Milk; Determination of cow manure in —. Moisture content and solubility of cow manure. G. B. Taylor. J. Dairy Sci., 1917, 1, 303–312. Bull. Agric. Intell., 1918, 9, 991.

WHEN the quantity of manure present in the milk is large, it can be determined fairly accurately by a chemical method, but in the majority of milks the amount of manure is too small to be determined chemically. The manure examined contained 83% of water. Air-dried manure contained 6% of water; 5% of the remaining solid matter was soluble in milk; this would indicate that only 11% of air-dried manure dissolved in milk. Nearly 85% of fresh cows' manure dissolved in milk, 83% of this being water. Manure, in whatever condition, was less soluble in milk than in water.—W. P. S.

Butter; Influence of salt on the changes taking place in storage —. R. M. Washburn and A. C. Dahlberg. J. Dairy Sci., 1917, 1, 114–126. Bull. Agric. Intell., 1918, 9, 996–997.

It is generally believed that salt improves the keeping quality of butter, but it has been observed that unsalted butter in commercial cold storage keeps as well as, or better than, salted butter. Investigations carried out by the authors show that salt, exclusive of its antiseptic property, hastened the deterioration of butter; when stored at -15°F. (-25°C.), unsalted butter kept as well as salted butter. The bacteria decreased more rapidly at -15°F. (-25°C.) in unsalted butter than in salted butter and increased more rapidly at 58°F. (15°C.). The acidity of unsalted and salted butters increased uniformly at -15°F. (-25°C.) but at 58°F. (15°C.) the increase was greater in the unsalted butter. Moisture was lost from the salted butter but not from the unsalted butter kept at -15°F. (-25°C.).—W. P. S.

Butter; Relation of Oidium lactis and Penicillium to the keeping qualities of —. W. B. Combs and C. H. Eckles. J. Dairy Sci., 1917, 1, 347–355. Bull. Agric. Intell., 1918, 9, 992–993.

MOULD spores do not germinate or grow in butter; the growth of moulds on butter is due to contamination from outside and does not proceed readily. The taste of cream is considerably affected by the growth of *Oidium lactis* and *P. chrysogenum* when the cream is sweet, but mould growth on sour cream does not produce an objectionable flavour; the growth of these moulds on cream has a detrimental effect on the butter made from the cream. Abnormal flavours which develop in the butter are due to enzymes which are secreted by moulds in the cream. Pasteurisation greatly improves the keeping quality of butter made from mouldy cream but it does not check completely the action of the enzymes produced.—W. P. S.

Butter, lard, etc.; Crismer test for the detection of foreign fat in —. A. W. Stewart. J. State Med., 1918, 26, 312–315.

INFORMATION similar to that furnished by the Valenta value can be obtained by a modification of Crismer's test (this J., 1895, 1069). Three c.c. each of filtered fat and absolute alcohol are pipetted into a test-tube and heated over a small flame with continuous stirring with a thermometer until

the mixture is clear. The tube is then removed from the flame and the contents stirred until turbidity appears. The temperature at which this occurs constitutes the Crismer number. Butter fat gives a result varying from 50.5 to 57, whilst margarine has a value over 65 if it is composed of animal fat, and under 50 if prepared from vegetable fat. The Crismer test yields more consistent results than can be obtained by the Valenta method, because absolute alcohol of constant quality can readily be obtained, whereas the commercial glacial acetic acid required for the Valenta test differs considerably in its moisture content from time to time (see Fryer and Weston, this J., 1918, 64A). The fat must be free from moisture and quite clear, and can generally be so obtained by filtration in a hot water oven through a dried filter paper. The Crismer test may also be applied to lard, the normal value for which is 76 to 77. The Crismer values of other fats are as follows:—Sesame oil 67.5, almond oil 64, cottonseed oil 61.5, arachis oil 57.5, olive oil 56, cacao butter 47, tallow 34.5, palm oil 22, coconut oil 15 to 19.5, palm kernel oil 13.5. Rape oil is characterised by its insolubility at the boiling point of the mixture.—H. W. B.

Egg; Chemical and physical constants of the oily matter of the —. F. Schaffer and L. Meyer. Mitt. Lebensmittelunters. u. Hyg., 1918, 9, 135–136. Bull. Agric. Intell., 1918, 9, 995.

THE nature of the solvent has a considerable influence on the physical and chemical constants of the oil extracted from egg yolk; petroleum spirit extracts the oily matter alone, whilst chloroform extracts the cholesterol and a portion of the lecithins as well. Results obtained by the authors show that the refractive index of the oil lies within the limits recorded in literature; the iodine value is, on an average, 74 to 75. The phosphorus content of the lecithins diminishes gradually during storage, being 1.27% (as P_2O_5) in the case of fresh eggs and 0.8% after storage for 2 years.—W. P. S.

Foods; Detection of decomposition in —. K. Brauer. Chem.-Zeit., 1918, 42, 421–422.

INCIPIENT decomposition in sausages, preserved foods, etc., may be detected by inoculating dextrose-bouillon with a small portion of the sample, incubating at 38°C. for 24 to 48 hrs., and noting whether or not gas is produced during this period. If there is formation of gas, organisms capable of decomposing the food are present; further investigation by sub-cultures will, if desired, indicate the kind of organism. The dextrose medium employed is prepared by dissolving 1 gm. of meat extract in 100 c.c. of water, adding 1 gm. of peptone and 0.5 gm. of sodium chloride, sterilising the solution, then adding 1 gm. of dextrose, introducing portions of the solution into a series of Eimhorn fermentation tubes, and again sterilising for a short time.—W. P. S.

Ergotinine. Wolter. See XX.

PATENTS.

Wheat for milling purposes; Preparatory treatment of —. J. S. Remington, Grange-over-Sands, Lanes. Eng. Pat. 118,431, July 28, 1917. (Appl. No. 10,897 of 1917.)

THE wheat is washed with a 10% solution of potassium or sodium carbonate, then centrifuged, and dried in a current of cold (preferably refrigerated) air.—W. P. S.

Bread; Manufacture of leavened — H. A. Kohman, Pittsburgh, Pa., Assignor to Ward Baking Co., New York. U.S. Pat. 1,274,898, Aug. 6, 1918. Date of appl., Feb. 15, 1918.

A MEM-LIKE product containing diastatic and proteolytic enzymes, produced by the action of *Aspergillus oryzae* on grains, seeds, maize, legumes, etc., is added to the flour, yeast and other ingredients of dough, and the mixture is fermented.—W. P. S.

Soya bean milk; Manufacture of — and the complete utilisation of by-products. W. J. Melhuish, Poole, Dorset. Eng. Pat. 118,535, Dec. 10, 1917. (Appl. No. 18,279 of 1917.)

Soya beans are immersed in water at 60° C., allowed to cool in the water for 24 hrs., then drained and ground; 16 lb. of the meal is mixed with 100 lb. of water containing 110 grains of potassium phosphate, and the mixture is stirred and heated at 95° C. for 45 mins. The mixture is then passed through a filter-press, the press-cake being afterwards transferred to a hydraulic press to obtain a feeding cake and separate the oil. The liquid from the filter-press is centrifuged, heated under reduced pressure, and stirred with the addition of suitable oils (sesame, earthenut, coconut, etc.), then cooled to 36° C., treated with a culture, salts and acids (e.g., butyric acid) are added, and after the lapse of sufficient time for the culture to grow, the whole mixture is sterilised at 70° C., cooled to 16° C., and stored. The separator slime may be mixed with the foots obtained in clarifying the soya bean oil, and the mixture used as a soap base.—W. P. S.

Whey extract for use as a food and process of producing the same. H. H. Senior, East Stour, Dorset. Eng. Pat. 118,874, Aug. 28, 1917. (Appl. No. 18,354 of 1917.)

WHEY is heated at about 190° F. (88° C.) for 1½ hrs., then cooled, and the coagulated substances are separated, drained, dried slowly and ground to a fine powder. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 23,127 of 1909; this J., 1910, 1327.)—W. P. S.

Milk; Process of making a new food product of — P. W. Turney, Portland, Oreg. U.S. Pat. 1,274,218, July 30, 1918. Date of appl., Mar. 22, 1917.

FRESH milk is curdled by an enzyme, the action of which is allowed to continue until the precipitate becomes flocculent, when the temperature is rapidly lowered to prevent further enzyme action. The low temperature is maintained until the precipitate is required to be used.—J. H. J.

Milk; Process of treating — N. D. Nielsen, Elyria, Ohio. U.S. Pat. 1,274,748, Aug. 6, 1918. Date of appl., Feb. 11, 1918.

MILK at 40° F. (4° C.) is introduced into a vessel provided with a jacket heated at 212° to 220° F. (100° to 105° C.); the milk is stirred until its temperature is 110° to 160° F. (43° to 71° C.) and then cooled in the same vessel while the stirring is continued.—W. P. S.

Milk and the like; Process of treating — N. D. Nielsen, Elyria, Ohio. U.S. Pat. 1,274,750, Aug. 6, 1918. Date of appl., Mar. 22, 1918.

MILK or other liquid is sterilised at 145° F. (63° C.) by placing it in a jacketed vessel and introducing a heated condensable gas into the jacket; a cooling medium is then admitted to the jacket so that the

gas is condensed and a partial vacuum created in the jacket. After 30 mins., a cooling medium is again admitted to the jacket so as to cool the milk to 36° F. (2° C.), the cooling medium is then withdrawn, and the condensable gas again introduced and condensed, so that the liquid is then contained in a vacuum-jacketed vessel.—W. P. S.

Milk and other liquids readily decomposed by heat [e.g., blood, serum, must, etc.]; Sterilisation of — O. Lobeck, Leipzig. Ger. Pat. 306,924, Sep. 30, 1913.

The liquid is spread out by means of a current of air or other gas on the surface into very thin layers on a suitable support and exposed for a short time to a sterilising temperature.—L. A. C.

Foods and other products; Drying of — L. P. Bowler, A. Paterson, and L. S. Levy, London. Eng. Pat. 118,911, Oct. 2, 1917. (Appl. No. 14,251 of 1917.)

THE material to be dried, such as fruit, vegetables, meat, fish, copra, coal, etc., is placed on trays arranged in a closed chamber through which a current of dry heated air is drawn by means of a pump. The air is heated by passing through a chamber containing a steam coil and then enters a chamber fitted with air filters and also containing drying substances, such as calcium chloride; this filter chamber is provided with a heat-insulating jacket. After traversing the heating coil the steam may be conducted to a jacket surrounding the drying chamber. Dehydrating substances may be placed in the air-heating chamber and in the drying chamber, and also arranged between the drying chamber and the pump.—W. P. S.

Fruit; Apparatus for drying — T. W. W. Forrest, Oakland, Cal. U.S. Pat. 1,275,547, Aug. 13, 1918. Date of appl., Apr. 1, 1918.

THE fruit is dried on an endless conveyor constructed of open-mesh material and mounted on a removable frame fitted in a vacuum chamber. Heating devices and means for operating the conveyor are provided in the chamber, and the inlet and outlet passages for the fruit are fitted with valves.—W. P. S.

Eggs; Dried — in powder form. E. S. Spencer and F. F. Kemp, London. Eng. Pat. 119,007, Apr. 17, 1918. (Appl. No. 6502 of 1918.)

WHOLE eggs are dried until the water content is reduced to 5%; egg yolks are dried separately in a similar manner. Five parts by weight of the dried whole egg is then mixed with 2 parts of the dried yolks. The resulting product is miscible with water and contains protein 42.6, fat 49.0, ash 3.4, and water 5%.—W. P. S.

Vegetable proteid substances; Process of manufacturing — S. Satow, Sendai, Japan. U.S. Pat. 1,275,308, Aug. 13, 1918. Date of appl., Nov. 25, 1916.

VEGETABLE substances are freed from oil, extracted with water, the extract is clarified, and the soluble proteins then precipitated by the action of lactic ferment.—W. P. S.

Proteid matter from corn [maize]; Process of obtaining — J. Takamine, New York, and S. Satow, Sendai, Japan. U.S. Pat. 1,275,324, Aug. 13, 1918. Date of appl., Nov. 25, 1916.

MAIZE is steeped in water, crushed, the germs are removed, and the mass is ground with water; after

separating bran and starch, the substances remaining in the liquid are separated in the form of a "meal" and transferred to a "liquid solution," and the proteins are precipitated from this solution.
—W. P. S.

Food products of starchy material; Method of preparing —. F. G. Lorenzen, Assignor to Kellogg Toasted Corn Flake Co., Battle Creek, Mich. U.S. Pat. 1,275,711, Aug. 13, 1918. Date of appl., Mar. 30, 1918.

STARCHY material is subjected to the action of steam for about 2–4 hrs., first at a pressure of less than 2 lb. per sq. in., then at a higher one (10–20 lb. per sq. in.), the globules being thereby gelatinised. They are then separated, dried at 100°–110° C., and subsequently subjected to a sharp dry heat, whereby they are puffed.—A. B. S.

Cotton-seed flour and process of making the same. G. A. Baumgarten, Schulenburg, Tex. U.S. Pat. 1,276,477, Aug. 20, 1918. Date of appl., Sep. 21, 1915.

COTTONSEED is freed from bran, and cooked under steam-pressure for substantially 1 hour 40 mins. at about 238°–240° F. (114.5°–115.5° C.), or for a sufficient length of time at a sufficient temperature to rupture the oil-cells. This cooking process may be effected in a series of cookers the steam-pressure in which is successively reduced. The oil and disintegrated coating of the oil-cells are separated by expression, and the residual cake is dried, ground, and bolted to produce flour.—C. A. M.

Food; Substitute highly-nitrogenous — and process of producing the same. N. Moskovits and K. A. Jacobsen, Assignors to Moskovits Mor és Fia, Nagy-Várád, Hungary. U.S. Pat. 1,277,336, Aug. 27, 1918. Date of appl., Feb. 26, 1916.

SEE Eng. Pat. 100,135 of 1916; this J., 1916, 1128.

XIXB.—WATER PURIFICATION; SANITATION.

Water purification; Baryta as substitute for soda in —. F. Hundeshagen. Z. öffentl. Chem., 1918, 24, 159–167.

IN the softening of boiler water containing calcium sulphate, the use of barium chloride results in the precipitation of barium sulphate which does not form a crust or corrode the boiler. If barium carbonate is used, calcium sulphate is converted into barium sulphate and calcium carbonate. The process leads to some loss of barium carbonate which is used in excess, but if the precipitant is added to the hot water, only 5–10% in excess need be used and the precipitation of calcium is complete. Barium hydroxide reacts with calcium sulphate to form barium sulphate and calcium hydroxide. The latter is objectionable on account of its tendency to form a hard crust on the hottest parts of the boiler. In the presence of calcium bicarbonate, barium sulphate and calcium carbonate are precipitated. If the calcium sulphate is in excess, a little calcium hydroxide is formed, but this can be removed with barium carbonate or with sodium carbonate. Baryta water precipitates magnesium hydroxide from magnesium salts. Barium aluminate acts as a precipitant in a similar manner to barium hydroxide. Formule and examples are given for calculating the amount of precipitant to be used for various combinations of hardening salts.—J. H. J.

Catalase. Jacoby. See XVIII.

Anthrax. (1) Kelser. (2) Berg. See XX.

PATENTS.

Softening water. E. Edser, S. Tucker, and Minerals Separation, Ltd., London. Eng. Pat. 118,668, Sep. 3, 1917. (Appl. No. 12,624 of 1917.)

THE water to be softened is treated with tri- or disodium phosphate and caustic soda, or other suitable reagents, to precipitate the hardening salts. The precipitate produced is formed into a froth by addition of sodium oleate and violent agitation with air. On allowing the water to come to rest, the precipitate floats on the surface. Iron salts also may be removed from water by this method.

—J. H. J.

Water; Apparatus for heating and deoxidising —. F. N. Speller, Pittsburgh, Pa. U.S. Pat. 1,274,099, July 30, 1918. Date of appl., Apr. 29, 1918.

THE apparatus consists of a water heater containing a series of thin plates of steel or iron for deoxidising the water.—J. H. J.

Filtering apparatus [for water]. C. S. Smith, Brooklyn, N.Y. U.S. Pat. 1,276,129, Aug. 20, 1918. Date of appl., May 18, 1914. Renewed Jan. 10, 1918.

A TANK is fitted with transverse partitions forming galvanic couples, between which are layers of a filtering medium of carbon and aluminium. The water to be filtered is forced upwards through the tank under pressure, and the residue descends to the bottom.—J. H. J.

Softening water; Method of and apparatus for —. T. R. Duggan, Assignor to The Permutit Co., New York. U.S. Pat. 1,276,629, Aug. 20, 1918. Date of appl., Oct. 23, 1916.

A WATER-SOFTENING bed of exchange-silicates containing lime and magnesia is regenerated after use by passing an upward current of sodium chloride solution through the bed as long as lime and magnesia continue to be removed, drawing off the contaminated solution at the surface of the bed after a single passage, and flushing out the residue of the solution.—J. H. J.

Tetra-iodo-hexamethylenetetramine [antiseptic] composition. K. G. Falk and K. Suglura, Assignors to G. B. Pegram, New York. U.S. Pat. 1,275,162, Aug. 6, 1918. Date of appl., June 23, 1917.

A COMPOSITION, for use as an antiseptic, healing, or sterilising agent, comprises 1% of tetra-iodo-hexamethylenetetramine diffused uniformly throughout a liquid solvent or vehicle, such as collodion.—B. N.

Antiseptic and germicidal tablet. A. Rogers, Assignor to C. T. Davis, Brooklyn, N.Y. U.S. Pat. 1,276,119, Aug. 20, 1918. Date of appl., Apr. 2, 1918.

THE tablet consists of potassium mercuric iodide with a sufficient quantity of a stabilising agent, such as an iodide, to prevent the formation of insoluble mercuric iodide, and with a sufficient quantity of sodium chloride to act as a binder and to give a solution of the tablet a tonicity approximating to that of the blood.—J. H. J.

Preserving organic materials by the use of X-rays; Apparatus for —. D. C. Gillett, Tampa, Fla. U.S. Pat. 1,275,417, Aug. 13, 1918. Date of appl., Apr. 14, 1917.

THE apparatus consists of an outer chamber impervious to X-rays and an inner chamber with one or more of its sides pervious to X-rays. At the pervious side of the inner chamber is a chamber containing several X-ray tubes connected to a source of electric current.—J. H. J.

Water; Apparatus for purifying —. L. Linden, London, and W. J. Stewart, Belfast. U.S. Pat. 1,276,234, Aug. 20, 1918. Date of appl., July 9, 1915.

SEE Fr. Pat. 474,907 of 1914; this J., 1915, 1112.

Sterilising milk, etc. Ger. Pat. 306,924. See XIXA.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Ergotinine; Detection of —. L. Wolter. Chem.-Zeit., 1918, 42, 446.

ERGOT of rye contains about 0.12% of ergotinine, about two-thirds of which can be separated in the amorphous condition and about one-third in the crystalline form by Tanret's method. The potassium mercuric iodide reagent for alkaloids gives a distinct reaction with an alcoholic solution of 1 part of ergotinine in 1,240,000. Tanret's reaction (yellowish-red zone changing to violet and then to blue), with sulphuric acid added to the solution in ether, alcohol, or ethyl acetate, is characteristic of ergotinine. In Rosenthaler's modification sulphuric acid is added to a solution of the alkaloid in glacial acetic acid which has previously been treated with a trace of ferric chloride, whilst Keller applies the test by adding strong sulphuric acid containing a trace of ferric salt to a solution of ergotinine in ethyl acetate. The reaction may be rendered more sensitive by using a trace of hydrogen peroxide in place of ferric chloride as the oxidising agent, and is then capable of detecting 0.01 mgrm. as against 0.02 mgrm. by Tanret's original test. It is essential that the solution of the alkaloid should not be too concentrated, or misleading colorations will be obtained. (See also J. Chem. Soc., Nov., 1918.)

—C. A. M.

Eserine. J. Herzig and H. Lieb. Monatsh. Chem., 1918, 39, 285–292.

THE micro-method for the determination of imino-methyl groups in eserine and eseroline indicates the presence of one more such group than the ordinary macro-method. If, in the ordinary method, the proportion of hydriodic acid to substance is increased, e.g. by taking 0.1 gm. of eserine to 29 c.c. of hydriodic acid, the result indicates three methyl groups in agreement with the micro-method. It is possible that the third difficultly removable alkyl group may be an ethyl radicle, and not methyl. (See also J. Chem. Soc., 1918, i., 501.)—D. F. T.

Scoparin. J. Herzig and G. Tiring. Monatsh. Chem., 1918, 39, 253–267.

SCOPARIN, the yellow substance present in *Spartium scoparium*, when treated with diazomethane, can be made to yield a dimethyl and a trimethyl derivative, whereas with silver oxide and methyl iodide a heptamethyl derivative is obtainable. Scoparin, therefore, contains at least seven hydroxyl groups. It also contains a methoxyl group. The composition

of these products indicates a formula $C_{29}H_{35}O_{11}$ for scoparin (compare Goldschmidt and von Hemmelmayr, this J., 1895, 63; see also J. Chem. Soc., 1918, i., 503).—D. F. T.

Symptomatic anthrax (blackleg); Methods of immunisation against —. R. A. Kelsner. J. Agric. Res., 1918, 14, 253–262.

THE medium found to be the best for growing the bacillus of symptomatic anthrax in order to produce a true toxin was a dextrose-peptone bouillon, of which the peptone was prepared as a solution direct from pigs' stomachs. Flasks were filled with this medium up to the neck, and several c.c. of a recently isolated, virulent culture of the bacillus added to the bottom of each. After 10 days' growth, the culture was filtered through a Berkefeld filter and the filtrate preserved with chloroform. This product was found to possess valuable immunising properties against blackleg.—J. H. J.

Symptomatic anthrax (blackleg) toxin; Concentration of —. W. N. Berg. J. Agric. Res., 1918, 14, 263–264.

TOXIN, prepared as described in the preceding abstract, was placed in Petri dishes and frozen. The dishes and contents were then placed in evacuated desiccators and maintained at -9°C . for 1–2 days, when the toxin had evaporated to a paste. —J. H. J.

Oxalic acid; Separation of — from tartaric acid. A. Bau. Chem.-Zeit., 1918, 42, 425–426.

THE solution, containing not more than 0.2% of oxalic acid, is treated with an excess of boric acid (at least 0.25 mol. of boric acid per mol. of tartaric acid is required to prevent the precipitation of the latter) and one-fifth of its volume of calcium acetate reagent. The mixture is kept in an ice-chest for about 40 hrs., the precipitated calcium oxalate then collected, washed, ignited, and the resulting calcium oxide titrated with N/10 hydrochloric acid. One litre of the reagent dissolves 3.42 mgrms. of calcium oxalate and 1 litre of wash-water dissolves 4.64 mgrms.; the volumes of the filtrate and wash-water must be noted, and the corresponding correction applied to the result. The calcium acetate reagent is prepared by dissolving 350 grms. of sodium acetate in 300 c.c. of water, and adding 500 c.c. of this solution to 25 grms. of calcium chloride dissolved in 500 c.c. of 50% acetic acid; the mixture is kept in an ice-chest for 24 hrs. and then filtered. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Acetic acid and acetone; Industrial developments relating to the manufacture of —. H. Hibbert. Chem. and Met. Eng., 1918, 19, 397–400.

ON the outbreak of war the demand for acetic acid and acetone rose to such an extent that the output of the wood-distillation industry was totally inadequate to meet the requirements. Working in conjunction with the British Government, the U.S. Industrial Chemical Co. erected a large plant which is now producing acetic acid by the oxidation of alcohol obtained from molasses by the quick fermentation process. The plant has an output of 70,000 lb. of acetic acid (calculated at 100%) per day. The oxidation of the alcohol to acetic acid is effected in generators filled with beech shavings. It is most probable that this process will not be profitable under normal conditions. Acetone is also produced in Toronto and in the United States by the Fernbach process, in which starch from maize or other grain is fermented by a special ferment, which resolves the carbohydrate into a mixture

of butyl alcohol and acetone. The output of acetone at the Toronto plant is 100 tons per month, and at the United States plant nearly 250 tons. A process has been worked out and put into operation in Canada (output 55,000 lb. of 100% acetic acid per day) which is based on the German patents for the manufacture of acetic acid from acetylene. When acetylene gas is passed through a solution of a mercury salt in dilute acid, it combines with the water yielding acetaldehyde, which is readily converted by atmospheric oxygen into acetic acid. The process is important as a potential source ultimately of cheap acetic acid, and of acetaldehyde for probable new industrial uses. In Germany and in Switzerland large electrical installations have been erected for the manufacture of alcohol and acetic acid from calcium carbide. The wood-distillation industry is threatened with dangerously keen competition in the future. Development on scientific lines, and research for the exploitation of untapped sources of revenue in the acetone, crude acetone oils, and wood tar are imperative.—S. S. A.

Acetol; New reaction for —. O. Baudisch. *Biochem. Zeits.*, 1918, 89, 279—280.

A DILUTE solution of acetol in water containing sodium hydroxide is boiled for a few minutes with *o*-aminobenzaldehyde. The mixture is cooled, acidified, and then made alkaline again with sodium bicarbonate. A fluorescent solution is obtained from which 3-hydroxyquinoline can be extracted by ether; on distilling off the ether it is obtained as a white residue, which gives a deep red colour with ferric chloride in alcoholic solution. The alcoholic solution also gives a brilliant blue fluorescence on dilution with water. These two reactions are characteristic. (See also *J. Chem. Soc.*, Nov., 1918.)—S. B. S.

Potash, etc., from kelp. Higgins. See VII.

Citric acid esters. Pinnow. See XII.

PATENTS.

1,8-Dihydroxyanthranol; Manufacture of —. Manufacture of 1-hydroxyanthranol. Manufacture of 1-hydroxy- and 1,8-dihydroxyanthranol. *Farbenfabr. vorm. F. Bayer und Co. Ger. Pats.* (A) 296,091, Oct. 30, 1915, (B) 301,452, Feb. 20, 1916, and (C) 305,886, Apr. 6, 1917.

(A) 1,8-DIHYDROXYANTHRANOL, which is a valuable remedy for psoriasis and other skin diseases, is obtained by the reduction of 1,8-dihydroxyanthraquinone by zinc and acid. (B) 1-Hydroxyanthraquinone is reduced by zinc and acid, yielding 1-hydroxyanthranol, of value as a remedy for psoriasis. (C) Instead of the hydroxyanthraquinones as in (A) and (B), their alkyl ethers may be used. These are readily obtained by boiling 1-nitro- or 1,8-dinitroanthraquinone with alcoholic alkali.

Compound of lime and tannic acid; Manufacture of a — soluble with difficulty in dilute acids [gastric juice]. Knoll und Co., Chem. Fabr., Ludwigshafen. *Ger. Pat.* 306,979, Nov. 22, 1914.

BASIC calcium tannate is heated for some time at a high temperature; the compound so produced is insoluble in the gastric juice, but is decomposed in the intestine to lime and tannic acid.—L. A. C.

Dentifrice. U.S. Pat. 1,275,779. See V.

Aqueous solutions of hydrocarbons. *Ger. Pat.* 306,059 See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Gelatin [photographic plates]; Reticulation of —. S. E. Sheppard and F. A. Elliott. *J. Ind. Eng. Chem.*, 1918, 10, 727—732.

THE immediate cause of reticulation of the surface of photographic negatives is the production of restricted tangential dilation, partially arrested, during swelling and drying of the gelatin film. It may be produced by the combined action of both a swelling or softening agent (hot water, potassium iodide) and a hardening agent (chromic acid, mercuric iodide). Reticulation generally starts in one or more regions of the plate and spreads, and it seems that in its earliest stages it involves something like the nucleation of a crystallising solution. In the ordinary development of a negative it is probable that incipient reticulation is proceeding, foreign nuclei being available; different developers and treatments affect the "graininess" of the developed image, and alterations in the swelling equilibrium by changing from an acid to an alkaline medium in operations subsequent to development are liable to increase any incipient reticulation.—W. P. S.

PATENT.

Photography; Substance for use in — and method of making the same. A. de Brayer, Paris. U.S. Pat. 1,277,048, Aug. 27, 1918. Date of appl., Apr. 20, 1917.

SEE Eng. Pat. 105,920 of 1917; this J., 1918, 224 A.

XXII.—EXPLOSIVES; MATCHES.

High explosives; Initial priming substances for —. G. B. Taylor and W. C. Cope. U.S. Bureau of Mines, Tech. Paper 162, 1917. 32 pages.

Tests were made to ascertain the minimum weights of various primers required to detonate completely trinitrotoluene and tetryl (tetranitromethylaniline), the "sand test" (this J., 1916, 1132) being used to ascertain the degree of detonation of the nitro-compound. Tests made with mixtures of mercury fulminate and various oxygen carriers did not disclose any single property of the oxidiser as having a direct relationship with the priming efficiency of the mixture. Oxidisers varying widely in specific gravity, heat of formation, percentage of available oxygen, character of the non-volatile product of explosion, and general chemical relationship, yielded about equally efficient mixtures. In general, salts of the oxyhalogen acids made efficient mixtures; oxides and nitrates of heavy metals yielding the free metal on decomposition made especially efficient mixtures; heavy metal oxides which are reduced to lower oxides were ineffective. Mercury fulminate was found to be more efficient when uncompressed than when compressed. It seemed also that the sensitiveness of trinitrotoluene to detonation decreased with the degree of compression. The efficiency of primers containing lead azide increased with the pressure of loading. The priming efficiencies of nitrodiazobenzene perchlorate (Herz, *Fr. Pat.* 450,897; this J., 1913, 627) and hexamethylene-triperoxide-diamine (Von Girsawald, this J., 1912, 1058; 1913, 992) were found to be high, 0.10 grm. and 0.15 grm. of these substances respectively being equal to 0.30 grm. of lead azide or 0.35 grm. of mercury fulminate for detonating trinitrotoluene. The "sand test," in which the ability to break up quartz sand in a "sand bomb" is measured, showed no

parallelism between quantity of sand crushed, and priming efficiency as measured by the relative minimum weights required to cause detonation, but appeared rather to be a test for "strength," the values being in nearly the same order as Berthelot's "characteristic products" (QV_0 , where Q is the heat of explosion and V_0 the calculated volume of gaseous products of explosion at 0°C . and 760 mm. from 1 gm. of explosive). The authors consider that the effectiveness of a detonator in practice depends upon explosive energy, that may be separated into an intensity factor ("quickness," depending upon acceleration of the explosive decomposition), and a capacity factor, "strength." The "sand test" may be regarded as a measure of "strength," and the lead-plate test, and the shattering effects on glass tubes, as tests of "quickness." The behaviour of silver acetylide, which although an inefficient primer yet markedly increases the effectiveness of mercury fulminate, is explained by its low "strength" and its great "quickness." Emphasis is laid on the value of the "sand test" for controlling the manufacture of a given priming composition, as although "quickness" is probably the more important of the two factors, this may be regarded as constant for a given material, and the "strength" then becomes a measure of the efficiency of a particular sample.—T. St.

Detonator compounds containing mercury fulminate; Analysis of —. P. Nicolardot and J. Boudet. *Ann. Chim. Analyt.*, 1918, 23, 192—194.

A portion of the sample is digested with ammonium sulphide solution, first for 2 hrs. in the cold and then for 1 hr. at 60°C . The mercury is thus converted into mercuric sulphide, which is collected and weighed. The filtrate from the mercuric sulphide is heated with ammonium sulphide and the precipitated antimony sulphide is collected and weighed. The solution from the antimony sulphide is evaporated, and the alkalis weighed as sulphates. A separate portion of the sample is tested for the presence of nitrates and chlorates. The mercuric and antimony sulphides are volatilised after being weighed, since they may contain traces of copper, zinc, or iron; any powdered glass in the sample will be found in the mercuric sulphide precipitate.

—W. P. S.

PATENT.

Explosive. F. G. L. Johnson, London, Assignor to Palmer-Perchlorate Powder Co. of Canada, Ltd., Montreal, Canada. U.S. Pat. 1,276,537, Aug. 20, 1918. Date of appl., Sep. 21, 1916.

See Eng. Pats. 14,866 of 1915 and 1480 of 1916; this J., 1916, 1236.

XXIII.—ANALYSIS.

Vegetable colouring matter [of myrtle-berry juice]; Use of — as indicator. C. Marini. *Annali Chim. Appl.*, 1918, 10, 32—36.

The berries of the myrtle (*Vaccinium myrtillus*, L.) contain a red colouring matter which has been shown to be identical with cyanocyanin, the red colouring matter of wine. The slight differences in the behaviour of the two colouring matters, on which are based methods of detecting myrtle-berry juice in wine, are due to the greater proportion of chlorophyll as an impurity in the colouring matter of grape juice. The colouring matter obtained by extracting myrtle berries with alcohol consists of two components, one of which is of a glucosidal character, and is converted into the other by hydrolysis with acids. It is a weak acid and forms

green salts, and may therefore be used as a sensitive indicator in alkalimetry. Red and green test papers may be made from a 90% alcoholic extract of the berries in a manner analogous to that used in the preparation of turmeric paper. (See also J. Chem. Soc., 1918, 1, 518.)—O. A. M.

Microchemical reactions of metals with rubidium and cesium chlorides. J. Vermande. *Pharm. Weekblad*, 1918, 55, 1131—1134.

DOUBLE chlorides of cesium and rubidium with mercury, silver, copper, bismuth, antimony, tin, lead, nickel, cobalt, cadmium, iron, zinc, manganese, and magnesium have been prepared. They are analogous to the corresponding double salts of potassium and sodium. It was not found possible to prepare double chlorides with arsenic, aluminium, calcium, strontium, barium, potassium, sodium, or lithium.—A. J. W.

Molybdenum [as ammonium molybdate]; Recovery of — [from residues]. S. Malowan. *Chem.-Zeit.*, 1918, 42, 410.

To recover molybdic acid used as a precipitant in phosphorus determinations, the liquors are precipitated with sodium or calcium phosphate; the yellow precipitate, after being washed and dried, is heated with excess of strong sulphuric acid until solution is complete, and the acid colourless. The cold liquid is poured into 8—10 times its volume of water and the molybdenum precipitated with excess of potassium ferrocyanide. The precipitate is filtered off after 3 hours, and washed with dilute ferrocyanide solution till free from sulphuric acid; it is then dried, separated from the filter, and ignited at a dark red heat to incipient fusion. The cold mass is leached twice with hot water, after which the molybdic acid is extracted with ammonia. The colourless solution is filtered and evaporated to dryness, the residue treated with a little water and hydrogen peroxide and the solution boiled to oxidise any lower oxides. The resulting solution of ammonium molybdate is diluted to a sp. gr. of 1.09 at 17°C . (i.e., 10%).—W. R. S.

Determining benzene, etc., in gases. Davis. See IIa.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL: PLANT; MACHINERY.

APPLICATIONS.

- Akt.-Ges. Kummder und Malter. Evaporation of liquids. 17,387. Oct. 24. (Switzerland, Feb. 26.)
 Battersby and Dunlop. Apparatus for separating materials of different densities. 16,782. Oct. 15.
 Bibb. 16,809. *See* II.
 Boby, Ltd., and Jennings. Apparatus for separating dust, etc., from gases. 17,462. Oct. 25.
 Bradley. 17,277. *See* XI.
 British Thomson-Houston Co. (General Electric Co.). Producing a high vacuum. 17,454. Oct. 25.
 Bynoe. Drying apparatus. 17,043. Oct. 18.
 Carpenter. Heating stills, etc. 17,121. Oct. 19.
 Carruthers and Co., Gourlay, Johnstone, and Young. Filters. 17,308. Oct. 23.
 Chambers. Grinding-machinery. 17,369. Oct. 24.
 Fletcher. Conversion of water pastes into oil pastes. 17,493. Oct. 26. (Australia, Aug. 15.)
 Hewett. Drying fruit, chemicals, etc. 17,157. Oct. 21.
 Jaslier. Drying apparatus. 16,729. Oct. 14. (Fr., Oct. 20, 1917.)
 Joubert. Furnaces. 17,124. Oct. 19. (Fr., Oct. 19, 1917.)
 Leendertz. Process for briquetting refuse. 16,826. Oct. 15. (Holland, Oct. 25, 1917.)
 Morison. Condensing plant. 16,818. Oct. 15.
 Mumford. Decolorising and purifying agents, and methods of making same. 16,757. Oct. 14.
 Peck. Filter apparatus. 17,256. Oct. 22.
 Pinkney. Mixing-machines. 17,293. Oct. 23. (U.S., Oct. 30, 1917.)
 Riley. Method for sampling. 16,780. Oct. 15.
 Soddy. Process for improving or restoring absorptive power of charcoal for gases. 17,071. Oct. 18.
 Steiger. 16,758. *See* VIII.
 Sturtevant Mill Co. Pulverising mills. 17,175. Oct. 21. (U.S., Feb. 23.)

COMPLETE SPECIFICATION ACCEPTED.

- 14,785 (1917) and 140 (1918). Mauss. Centrifugal separators for separating solid and liquid mixtures. (119,706.) Oct. 23.

II.—FUEL; GAS; MINERAL OILS AND WAXES: DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Ballingall and Dempster. Adaptation of dust, etc., arresting means to plant for manufacture of water gas. 16,711. Oct. 11.
 Bibb. Manufacture of briquettes. 16,809. Oct. 15.
 Boby, Ltd., and Jennings. 17,462. *See* I.
 Kirpotschnikoff and Klasson. Utilisation of peat as fuel. 17,125. Oct. 19.
 May. Coal-cakes and process of making same. 17,003. Oct. 17.
 Soc. de Chimie et Catalyse Industrielles. Production of rich gases by means of petroleum residues. 16,820. Oct. 15. (Fr., Feb. 20.)

Soddy. 17,071. *See* I.

Wade (Barrett Co.). Manufacture of bituminous material. 16,847. Oct. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

- 13,697 (1917). McClelland. Electrically producing a gas suitable for internal combustion engines, etc. (119,885.) Oct. 30.
 14,031 (1917). Aiton. Gas generators. (119,676.) Oct. 23.
 14,541 (1917). Tissier. Carbonisation of wood. (110,300.) Oct. 23.
 14,725 (1917). Pearse. Distillation of carbonisable materials. (119,700.) Oct. 23.
 15,134 (1917). Bradley. Retorts for distilling or carbonising coal, carbonaceous and other materials. (119,911.) Oct. 30.
 15,396 (1917). Glover, West, and West's Gas Improvement Co. Gas producers. (119,723.) Oct. 23.
 17,613 (1917). Dunstan. Purification of cracked oils. (119,751.) Oct. 23.
 2372 (1918). Westwood. Treatment of heavy fuel oils preparatory to burning. (119,977.) Oct. 30.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

- Brass. Manufacture of colours and dyes. 16,939. Oct. 17.
 Ellis (Chemical Works, formerly Sandoz). Production of blue sulphur colorants. 16,761. Oct. 14.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Andrew, and D. R. Cotton Mills. Treatment of canvas, etc. 17,119. Oct. 19.
 Carter, Davis, and Foster. Extraction or decortication of ramie, hemp, jute, etc. 17,014. Oct. 18.
 Cavanaugh. Soil-proof fabric. 16,724. Oct. 14.
 Gray and White. Separator for paper pulp. 17,130. Oct. 21.
 Kanegafuchi Boseki Kabushiki Kwaisha. Treatment of silk fibres, etc. 16,839. Oct. 15.
 Lacy and Slight. Impregnating articles of mill-board, etc., to render them waterproof. 17,165. Oct. 21.
 MacDonald, and Spicer and Sons. Vulcanised or parchementised fibre. 17,501. Oct. 26.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,825 (1917). Thompson (Plante). Fabric-dyeing processes. (119,881.) Oct. 30.
 17,721 (1917). Calico Printers' Assoc., Clegg, Farnworth, and Roberts. Printing fabrics and yarns. (119,947.) Oct. 30.
 499 (1918). Livesey and Haworth. Machines for printing yarn. (119,773.) Oct. 23.
 1592 (1918). Dudley. Dyeing machine. (113,094.) Oct. 23.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Amber Size and Chemical Co., and Weygang. Production and use of compositions possessing alkaline properties. 16,825. Oct. 15.

Ashcroft. Manufacture of anhydrous magnesium and/or calcium chlorides. 16,701. Oct. 14.

Ashcroft. Production of anhydrous magnesium chloride or anhydrous carnallite. 16,860. Oct. 16.

Ashcroft. Manufacture of oxides or salts of lungsten, or metallic tungsten. 17,313. Oct. 23.

Ashcroft. Manufacture of oxides or salts of metals, or of metals, or of non-metals, from ores, residues, etc. 17,314. Oct. 23.

Ashcroft. Manufacture of aluminium or its oxides or salts. 17,315. Oct. 23.

Barron. Compressed Epsom salts. 16,733. Oct. 14.

Calvert. Production of cyanogen compounds, ammonia, etc. 17,167. Oct. 21.

Dutt and Dutt. Manufacture of magnesium sulphate. 17,076. Oct. 18.

Dutt and Dutt. Manufacture of sodium carbonate and alumina. 17,077. Oct. 18.

Dutt and Dutt. Manufacture of potassium carbonate and alumina. 17,078. Oct. 18.

Dutt and Dutt. Manufacture of potassium salts. 17,079, 17,080, and 17,081. Oct. 18.

Haslup. Fixation of atmospheric nitrogen and production of ammonia, etc. 17,364. Oct. 21.

Haslup. Fixation of atmospheric nitrogen in a blast furnace. 17,365. Oct. 21.

Kestner. Filling material for Glover towers, etc. 17,065. Oct. 18.

Parkes and Pearson. Manufacture of nitrogen acids from ammonia. 16,827. Oct. 15.

Pickard and Shaw. Manufacture of nitric acid. 16,684. Oct. 14.

Quain. Apparatus for producing ozone. 17,047. Oct. 18.

Rockefeller Institute. 17,171 and 17,172. *See* XX.

Welch. Producing sulphuric acid. 17,226. Oct. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

15,711 (1917) and 3152 (1918). Mewellyn, Spence, and Spence and Sons. Production of aluminous compounds. (119,924.) Oct. 30.

1211 (1918). Baker. Recovery of ammonium chloride from ammoniacal liquor with the extraction of cyanides, etc. (119,971.) Oct. 30.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Pike. Magnesite refractories. 16,712. Oct. 14.

Steiger and Steiger. Gas-fired shaft kilns for burning or roasting non-sintering substances. 16,758. Oct. 14.

Vergniaud. Manufacture of crucibles. 17,253. Oct. 23.

Vergniaud. Drying crucibles artificially. 17,254. Oct. 23.

IX.—BUILDING MATERIALS.

APPLICATIONS.

De Bas. Production of artificial stone. 17,329. Oct. 23. (Holland, Apr. 2, 1917.)

Lea. Apparatus for mixing cement aggregates, etc. 16,856 and 16,857. Oct. 16.

Smith. 17,143. *See* XIII.

Steiger. 16,758. *See* VIII.

Wade (Barrett Co.). 16,847. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

749 (1918). Chance and Hunt, Holley, and Webb. Acid-resisting cement. (119,966.) Oct. 30.

992 (1918). Surle, and Squirestone, Ltd. Insulating materials for cold storage. (119,783.) Oct. 23.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Ashcroft. 17,313, 17,314, and 17,315. *See* VII.

Blair and Clapp. Manufacture of iron and steel. 17,509. Oct. 26.

Boving. Treatment and reduction of ores. 17,227. Oct. 22.

Cooper Co. Alloy. 16,804. Oct. 15. (U.S., Oct. 15, 1917.)

Harvey, and Harvey Gas Furnace Co. Regenerative or recuperative gas furnaces for heating or melting metals. 17,068. Oct. 18.

Haslup. 17,365. *See* VII.

Lang. Zinc cyanide process of extracting gold from quartz, etc. 16,985. Oct. 17.

Morrison and Thompson. Coating surfaces of metal with lead or its alloys. 16,695. Oct. 14.

Munden and Shilton. Crucible furnaces. 16,937. Oct. 17.

Price. Crucible furnaces for melting aluminium, etc. 17,151. Oct. 21.

Shedlock. Manufacture of alloys and electrodes therefor. 16,739. Oct. 14.

Soc. Lorraine des Anc. Etabl. de Diérich et Cie. Measuring hardness of bodies. 17,328. Oct. 23. (Fr., Nov. 12, 1917.)

Stevenson. Amalgam of mercury. 17,438. Oct. 25.

Williams. Crucible furnace. 16,772. Oct. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

14,531 (1917). Procter. Soldering mixtures. (119,688.) Oct. 23.

803 (1918). Tylor and Sons, and others. Furnaces for smelting and refining metallic swarf, etc. (119,779.) Oct. 23.

8874 (1918). Carpmuel (A.G. f. Autogene Aluminium Schweißung). Autogenous welding of aluminium or its alloys. (120,005.) Oct. 30.

10,379 (1918). Greenwood and Batley, and Clegg. Annealing furnaces. (119,841.) Oct. 23.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Bradley. Electrical treatment of gases. 17,277. Oct. 23. (U.S., June 21, 1916.)

Cave. Alkaline accumulators. 17,338. Oct. 23. (Fr., Nov. 28, 1917.)

Gerrard and Newbery. Electrodes. 16,762. Oct. 14.

Oldham and Oldham. Galvanic batteries. 17,258. Oct. 22.

Shedlock. 16,739. *See* X.

COMPLETE SPECIFICATION ACCEPTED.

13,697 (1917). McClelland. *See* II.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Fletcher. 17,493. *See* I.

Holzapfel. Manufacture of coating or preservative compositions. 17,375. Oct. 24. (Norway, May 3.)

Ligterink. Linoleum substitute. 17,471. Oct. 25.

Nevello. Paints. 17,228. Oct. 22.

Smith. Aircraft dope. 17,161. Oct. 19.

Smith. Varnish for wood preservatives. 17,143. Oct. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

15,022, 15,023, and 15,024 (1917). Morris and Nevill. Manufacture of white pigments. (119,711, 119,712, 119,713.) Oct. 23.

12,236 (1918). Rogers. Manufacture of oil pastes from wet precipitated pigments and separation of free water therefrom. (118,289.) Oct. 30.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATIONS ACCEPTED.

4968 (1917). Bennett and Mellows. Substitutes for indiarubber, vulcanite, etc. (119,878.) Oct. 30.

14,965 (1917). Watkins. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Bendixen. Tanning fish skins. 17,486. Oct. 26. (U.S., Dec. 29, 1914.)

Blanc. Manufacture of tanning liquors. 16,968. Oct. 17. (Fr., Sep. 17, 1917.)

Edwards, Kay, and Ward. Treatment of hides, skins, etc. 17,475. Oct. 26.

Mumford. Manufacture of glue, etc. 17,185. Oct. 21.

Sayer. Leather substitute. 17,431. Oct. 25.

COMPLETE SPECIFICATION ACCEPTED.

14,965 (1917). Watkins. Consolidation of leather scrap or refuse with crude or waste rubber. (119,902.) Oct. 30.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATION ACCEPTED.

7813 (1918). Furse. Manufacture of manure from refuse. (119,834.) Oct. 23.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Chemical Works, formerly Sandoz. Manufacture of ferments, etc. 17,193. Oct. 21. (Switzerland, Oct. 20, 1917.)

Kanegafuchi Bōseki Kabushiki Kaisha. Production of proteolytic enzymes. 16,840. Oct. 15.

Scott. Process for brewing beer, etc. 16,876. Oct. 16.

COMPLETE SPECIFICATION ACCEPTED.

7660 (1918). Boulard. Brewing of beer. (119,833.) Oct. 23.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Alcock, Brander, and Wagstaff. Treatment of frozen meat. 16,749. Oct. 14. (Australia, Sep. 5.)

Cullen. Manufacture of egg substitute. 17,399. Oct. 24. (New Zealand, Nov. 2, 1917.)

Greville. Food products. 17,221. Oct. 22.

Hewett. 17,157. *See* I.

Inray (Soc. Chem. Industry in Basle). Manufacture of vitamin preparations. 16,830. Oct. 15.

Leendertz. 16,826. *See* I.

Nicholson. Treatment of sewage sludge, etc. 16,740. Oct. 14.

Quain. Sterilisation of water, etc. 17,048. Oct. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

14,752 (1917). Callebaut. Regenerating damaged cereals, seeds, and flour, especially maize. (110,364.) Oct. 23.

15,624 (1917). Sleeman. Flour or meal. (119,923.) Oct. 30.

12,499 (1918). Mapleton's Nut Food Co., and Mapleton. Food preparation. (120,018.) Oct. 30.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Inray (Soc. Chem. Industry in Basle). 16,839. *See* XIX.

Rockefeller Institute for Medical Research. Arsenical compounds 17,172 and 17,173. Oct. 21. (U.S., Jan. 28 and June 13.)

COMPLETE SPECIFICATION ACCEPTED.

573 (1918). Myddleton. Manufacture of *p*-oxyphenylarsinic acid. (119,964.) Oct. 30.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Bloch and Renwick. Colour-sensitised photographic materials. 16,845 and 16,846. Oct. 15.

Kelley. Photographic films. 17,191. Oct. 21.

Marchant and Co. Photographic printing. 16,755. Oct. 14. (Australia, Sep. 11, 1917.)

COMPLETE SPECIFICATION ACCEPTED.

18,639 (1916). Watkins. Photomicrography. (119,876.) Oct. 30.

I.—GENERAL ; PLANT ; MACHINERY.

Hydraulic separation as applied to the recovery of fine coals, shales, and clays. J. M. Draper. Trans. Ceram. Soc., 1917-18, 17, 213—225.

The hydraulic separator designed by the author consists of a vertical tube, provided near the top with a perforated funnel, 15, and also with an

inlet, 5, at one side for water, and a second side inlet, 7, connected to another vertical pipe the free end of which is closed by an air valve so that this pipe forms a compensating water-column or balance. A sampling tube, 23, and observation windows, 22, are also provided. The separator is filled with water through the inlet pipe, 5, and the supply is adjusted until a strong current overflows at 3. The material to be treated is fed into the top of the apparatus and descends into the tubulure of the funnel, where the velocity of the water is at a maximum and is adjusted so that the heavier particles can descend into the lower part of the separator whilst the lighter ones rise and pass out with the overflowing water. The heavy particles pass through the rotary valve, 25, to the bottom of the apparatus and are removed by a screw conveyor, 13.

When dirty coal is led into the apparatus any shale or heavy mineral particles pass to the screw conveyor; the coal and fine clay pass out with the water and may be separated by passing this portion of the product over a No. 100 sieve, the clay and coal dust passing through the sieve and the remainder of the coal being washed down the sieve into a receiver. When a clay is fed into the apparatus the heavier impurities (pyrites, etc.) are separated and pass into the conveyor. A preliminary treatment with sieves is desirable where the material is composed of widely different sizes, the various grades being then dealt with in independent separators placed side by side.

—A. B. S.

Extraction of liquids; Apparatus for — in towers filled with Raschig's rings. F. Raschig. Z. angew. Chem., 1918, 31, 183—185.

The introduction of Raschig's rings (Eng. Pat. 6288 of 1914 and Ger. Pat. 292,622; this J., 1914,

907; 1916, 916) overcomes certain objections to the application of the counter-current principle to processes in which a liquid is purified by treatment with another liquid immiscible with it. The apparatus consists of an iron cylinder, 8 m. high and 60 cm. diam., in which a screen is fixed 1 m. from the base. On this screen rests a column (6 m. in height) of Raschig's rings (25 mm. diam.). An inlet tube (2 m. length and 30 cm. diam.) is fixed in the middle of the cylinder at the top, and serves to admit the heavier liquid, whilst the lighter liquid is introduced through a long upright tube which enters the cylinder just below the screen. The heavier liquid sinks ultimately to the bottom of the chamber below the screen, whence it passes out through a long upright tube, of such a height that the heavier liquid in this tube balances the column of the mixture in the cylinder. The lighter liquor overflows through an outlet in the side of the cylinder near the top. The runnings are always clear, any emulsion or other deposit settling on the rings, which are cleaned when necessary, by emptying the apparatus and running in a suitable solvent. This apparatus may be advantageously applied to the purification of mineral oils by treatment with sulphuric acid, the recovery of aniline from weak solutions by extraction with benzene, the extraction of acetic acid with ether, and of alcohol from dilute solutions with benzene.—S. S. A.

Decolorisation; Determination of the minimum quantity of decoloriser required for complete — by the adsorption formula. T. Tadokoro. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 405—411.

In calculating the amount of a decolorising agent required for complete decolorisation by means of the adsorption formula, $\log \frac{x}{m} = \log K + \frac{1}{n} \log C$, five or more different quantities of the decolorising agent were used, and the results plotted, $\log \frac{x}{m}$ being taken on the ordinate and $\log C$ measured on the abscissa. The point where a line connecting these five or more points cut the ordinate gave the value of $\log \frac{x}{m}$ in the case of $\log C = 0$; $\frac{x}{m}$ indicates the ratio between the quantity of decolorising agent and the total amount of colouring matter completely absorbed, and from this ratio the value of m may be calculated.—C. A. M.

Electrostatic precipitation. Eschholz. See XI.

PATENTS.

Furnaces; Regenerative —. J. R. C. August and H. V. Hooson, Halifax. Eng. Pat. 119,495, 26.9.17. (Appl. 13,817/17.)

The furnace gases pass through parallel horizontal flues, arranged in zigzag form, to the uptake, and the secondary air is preheated by passing in the reverse direction through flues alternating with the gas flues. The secondary air is controlled by dampers immediately before meeting the combustible gas. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 7210 of 1899, 186 of 1902, 6924 of 1911, and 101,983; this J., 1916, 1254.)

—W. F. F.

Furnaces. A. J. M. A. R. van der Does de Bijle, The Hague. Eng. Pat. 115,644, 9.5.18. (Appl. 7813/18.) Int. Conv., 2.5.17.

COAL is fed on to a non-perforated "dead" grate and is moved forward by a reciprocating plunger, 19, on to a grate, 6, of normal form, and thence forward to a perforated plate, the total area of the air passages of which is about one-tenth of those of the normal grate. This grate area is connected, along its full length, on both sides, by

ribbed plates, 9, to perforated plates, 11', at a lower level. At the rear end of the plates 11', recesses, 11, with closure plates, 12, are provided for the discharge of ash. Supplementary air passages, 16, are provided in the setting, with jets, 17, directed on to the top of the fire, 18.—W. F. F.

Furnaces; Gas heated —. H. J. Yates, Birmingham, S. N. and E. R. Brayshaw, Manchester. Eng. Pat. 119,553, 16.10.17. (Appl. 14,963/17.)

THE furnace is provided with a number of transverse passages beneath the floor, each having a gas burner at one end, and projecting upwards at its farther end some distance into the furnace. The hot gases, after passing through the furnace, pass through passages at the floor level into a vertical exhaust chamber above the ends of the transverse passages containing the burners. The gases pass upwards through this chamber to the exhaust, and the air supply for the burners passes downwards through pipes in the chamber and is thereby preheated.—W. F. F.

Furnace. W. J. Bagot, Bridgewater, Mass., Assignor to The Stanley Works, New Britain. Conn. U.S. Pat. 1,277,356, 3.9.18. Appl., 24.3.17.

ARTICLES which have been heated on a furnace hearth are pushed forward into an inclined shoot formed by a number of hollow spaced inclined members filled in with hollow blocks so as to form a flat inclined surface. The discharging edge of the hearth is supported by a transverse member which is braced by the hollow inclined members. A cooling medium is circulated through the hollow blocks and members, and is discharged through the inclined surface.—W. F. F.

Drying apparatus. L. B. Clarke, London. Eng. Pat. 119,156, 6.12.17. (Appl. 18,093/17.)

THE trays which support the material have deflector plates secured to the underside, so that when several trays are piled in a stack they may be inserted into or withdrawn from the drying chamber as one unit. Additional baffle-plates are provided, so that the direction of the air through the trays may be reversed.—W. H. C.

Dryer. L. C. Reed, Dallas, Tex. U.S. Pat. 1,276,957, 27.8.18. Appl., 21.2.18.

THE materials are passed successively in alternate directions through a superposed series of jacketed horizontal pipes provided with internal conveyor

worms and connected at alternate ends. A heating medium is passed through the jackets from a manifold at one side and discharged into a manifold at the other side of the series of pipes.—W. H. C.

Mills for crushing, grinding, and mixing colours, chemicals, drugs, ores, and the like; Means for covering in and discharging —. T. Breakell, Wirksworth, Derby. Eng. Pat. 119,367, 4.1.18. (Appl. 227/18.)

A GRINDING mill in which an eccentric vertical pestle is rotated by frictional contact with a rotating mortar, or *vice versa*, is enclosed in a casing of which the base forms a bed-plate for the mortar, and the removable cover contains the vertical bearing for the pestle. The cover may be made in two parts, one of which can be lifted off for feeding material or for inspection. An outlet opening in the bottom of the mortar is closed by a conical stopper of the same material, rotating with it and supported in a footstep bearing carried by a pivoted lever. The lever may be operated during rotation of the mortar, to withdraw the stopper.—W. F. F.

Gases and/or vapours; Means for carrying out catalytic or contact reactions between —. C. S. Roy, and T. Morson and Son, Ltd., London. Eng. Pat. 119,639, 26.6.18. (Appl. 10,536/18.) Add. to 116,151.

IN the apparatus described in the principal patent (this J., 1918, 397 A), the gauze catalyst is mounted in a number of separate rings each having pins projecting radially at opposite ends of a diameter. The pins engage in slots in short inner tubes which fit into the reaction tube so that the rings may be rotated till their planes are at any desired angle with the axis of the tube. The area of catalyst in the path of the gases is thereby varied. All the rings may be connected by links so that they may be operated simultaneously by external means.

—W. F. F.

Mixing or stirring means. N. D. Nielsen, Elyria, Ohio. U.S. Pat. 1,276,254, 20.8.18. Appl., 22.3.18.

A VERTICAL cylindrical tank has a saucer-shaped bottom with a central opening to which a valved elbow pipe is attached. A vertical shaft passes through a stuffing-box at the angle of the elbow pipe and extends upwards into the tank. A propeller having a diameter of less than one-third that of the tank is fixed to the upper end of the shaft so that the blades are partly above and partly below the line of junction between the vertical side and the bottom of the tank. The shaft is driven by gearing from below and as the propeller rotates it drives the liquid in the tank partly vertically upwards and partly horizontally outwards, causing thorough mixing.—W. H. C.

Liquids; Apparatus for separating —. Method of separating associated liquids. C. W. McKibben, Houston, Tex. U.S. Pats. (A) 1,276,386 and (B) 1,276,387, 20.8.18. Appl., 24.11.17 and 22.1.18.

(A) EMULSIONS of liquids of different sp. gr. and electrical resistance are separated by means of an apparatus consisting of a vertical vessel serving as a conduit for the emulsion and provided with means for separating it. Below the conduit is a settling chamber for the heavier liquid, provided with electrodes connected with an electro-responsive device whereby a valve is automatically opened when the electrical resistance of the contents of the chamber reaches a predetermined point. (B) Associated liquids are heated to a temperature below the b.pt. of the mixture, and made to pass through

a path between two active electrodes at sufficient velocity to prevent re-entanglement of the nascent streams formed between the two electrodes. Means are provided for the automatic reduction of the effective force of the applied current when the streams begin to form.—C. A. M.

Fire-extinguishing and fire-proofing composition. G. E. Ferguson, New York, Assignor to Pyrene Manufacturing Co. U.S. Pat. 1,276,742, 27.8.18. Appl., 12.12.14.

An aqueous solution of potassium carbonate, trisodium phosphate, and borax.—W. E. F. P.

Refrigerating-machine. F. G. Keyes, Boston, Mass., Assignor to National Automatic Refrigerator Co. U.S. Pat. 1,277,085, 27.8.18. Appl., 25.1.17.

An intermediate condenser is connected with a distilling chamber and a refrigerating chamber, the walls of the latter being composed of Monel metal or other poor conductor of heat.—W. H. C.

Low temperatures; Production of —. P. Langer, Aix-la-Chapelle. Ger. Pat. 307,359, 19.5.14.

In a refrigerating apparatus, the gas or vapour, after passing through one or more expansion nozzles, and through the refrigerating tubes, in which it absorbs heat, is passed gradually into a wider tube, the gradual decrease in velocity causing a corresponding increase in temperature and pressure. The gas or vapour is then led through a cooler and, by means of a compressor, the pressure is again brought to its initial value. After passing through a further cooler, the gas or vapour is led back to the expansion nozzles.—L. A. C.

Centrifugal liquid machine. B. R. Wright, Poughkeepsie, Assignor to The De Laval Separator Co., New York. U.S. Pat. 1,277,676, 3.9.18. Appl., 15.12.13.

The machine consists of a rotary bowl provided with a central vertical receiving passage. A stem projects upwards within and spaced from the inner wall of the receiving passage, and a screw conveyor is mounted in the annular space between the stem and the receiving tube. Vents are provided within the radius of discharge from the bowl for the escape of air or gases tending to retard the flow of the liquid through the apparatus.—J. H. P.

Cooling liquids or exposing them to air; Apparatus for —. A. Smallwood, London. Eng. Pat. 119,571, 23.11.17. (Appl. 17,265/17.)

Separating solids from liquids; Process and apparatus for —. P. T. Sharples, West Chester, Pa., U.S.A. Eng. Pat. 119,288, 27.9.18. (Appl. 13,965/17.)

See U.S. Pat. 1,232,104 of 1917; this J., 1917, 917.

Distillation of liquids; Method and apparatus for —. O. Stalhane and O. O. Kring, Ludvika, Sweden. U.S. Pat. 1,277,659, 3.9.18. Appl., 20.12.16.

See Eng. Pat. 110,821 of 1916; this J., 1917, 1262.

Tunnel furnaces. Eng. Pat. 119,366. See VIII.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Diffusion of oxygen through stored —. S. H. Katz. U.S. Bureau of Mines. Tech. Paper 170, 1917, 47 pages.

The effect of the size of the coal pieces and the proportion of voids in a coal pile, on the rate of diffusion of oxygen into the pile has been deter-

mined. The method consisted of interposing a layer of weathered coal, composed of pieces of known size, between an atmosphere of air on one side and nitrogen on the other. By analysing the gases periodically on both sides, the progress of diffusion was noted. The apparatus consisted of a vertical cylinder made in two halves, the upper half fitting into a water lute carried by the bottom half and thereby forming a closed vessel. The cylinder contained three compartments, one above the other—the middle one carrying the coal on a wire mesh support. The capacity of the upper and lower compartments was about 37 litres (8½ galls.) each, the depth of the coal usually being 8 inches. The sizes of coal ranged between 1 to 2 inch cubes and pieces passing through a sieve of 40-mesh (per linear inch) and remaining on 60-mesh. Tests were also made with coal of all sizes from a storage pile. The results indicate that the principles stated in Fick's law of diffusion are applicable to the diffusion of oxygen through the atmosphere in the voids of broken coal. If the proportion of voids in a mass of coal pieces is varied, the time required for a definite diffusion of oxygen increases approximately in inverse proportion to the percentage of voids. In storing coal in the air, factors other than diffusion may be accelerated or retarded by changes in voids; but if diffusion alone be considered, mixing the sizes of coal will reduce the oxygen entering the pile by diffusion and thus reduce oxidation from this source.—T. F. E. R.

Coal; Carbonisation of —. W. Savage. Chem. and Met. Eng., 1918, 19, 579–582.

In the manufacture of metallurgical coke a satisfactory product has been obtained in the beehive oven from coals containing up to 32% of volatile substances, whilst with by-product ovens the best results are given by harder coals with 23 to 28% of volatile substances. Coal containing more than 4% of moisture gives inferior results. In Smith's process (U.S. Pat. 1,177,727 and 1,224,424 of 1915; this J., 1916, 625; 1917, 636), an intermediate soft semi-coke containing 16 to 20% of volatile matter is made into briquettes with hard pitch under pressure and carbonised at suitable temperatures. The product, termed "carbo-coal," has been tested by several railway companies and by the U.S. Navy, and found to burn more readily than coke. With a rate of combustion of 27 lb. per sq. ft. of grate area per hour, it evaporated 12.8 lb. of water per lb. of fuel; and with 100 lb. combustion rate, 8.5 lb. of water. In working the process any grade of bituminous coal is reduced to about 12-mesh size, and fed continuously through a cylindrical retort containing agitators rotating at about 4 revolutions per hour. The retort, which is of refractory material, is heated to about 900° F. (480° C.) by the combustion of the gases evolved in the process, and, after distillation for about an hour, the material is cooled in a hopper, and then conveyed to crushing and pulverising machinery. The finely-divided semi-coke is incorporated with several per cent. of pitch in a mixing machine heated by direct steam, and the hot mixture is transferred to a briquetting machine of the roller type. The resulting briquettes are conveyed while hot to the carbonising retorts. As a rule only 4 to 5% of volatile matter is left in the residual "carbo-coal," this being sufficient to allow the product to burn readily in an open fireplace. From 2000 lb. of coal thus treated, 1440 lb. of "carbo-coal" briquettes are obtained and 560 lb. of gases and vapours, of which 200 lb. are permanent gases used for heating the retort. The vapours consist of 20 lb. of ammonia, etc., and 250 lb. of tar oils including benzol, toluol, naphthas, "motor spirits," cresote

oils, tar acids, pitch, etc. The tar obtained in the primary distillation of the coal has sp. gr. 1 to 1.06. It contains no naphthalene, anthracene, or phenol, but is rich in oils, tar acids, and cresols. The following table shows the liquid products yielded by one ton of coal in comparison with the amounts of by-products from the coke oven:—

	Distillation temperature	By-product coke oven		Carbo-coal, first distillation		Carbo-coal, second distillation	
		galls.	%	galls.	%	galls.	%
Light oil ..	Up to 77	0.27	3.47	1.58	6.60	0.003	0.05
Middle oil ..	77—110	0.44	5.85	3.29	13.70	0.036	0.60
Cresote oil ..	110—132	0.78	10.37	3.11	12.95	0.126	2.10
Heavy oil ..	132—182	1.26	16.81	8.88	37.00	2.485	41.42

—C. A. M.

Coal-gas manufacture: Technical scale tests on efficiency of — in Koppers' chamber ovens.

K. Bunte and E. Terres. J. Gasbeleucht., 1918, 61, 433–436, 445–450.

A SERIES of efficiency tests were carried out in 1912 at the Vienna-Leopoldau Gas Works on the Koppers system of chamber ovens. The plant consisted of 72 chamber ovens in ranges of 9. During the tests 5 ranges were working. Each chamber was 10.3 m. long and had a breadth of 540 mm. at the discharging end, tapering to 480 mm. at the charging end. Four regenerators were built under each oven for heating the cold producer gas and secondary air by heat from the waste gases. The ovens were supplied with producer gas from an external generating plant consisting of 12 Kerpely-Marischka producers, five of which were at work. The water jacket steam boilers on these producers generated all the necessary steam. The volume of producer gas made was calculated on a carbon balance sheet obtained from analyses. It was shown by one test that 11.17 kilos. of coke was burned in the producer during the carbonisation of 160 kilos. of coal and also that 663 calories had to be supplied as producer gas to the ovens to carbonise one kilo. of coal. The following thermal balance sheet was obtained for a 1-day test on the producers.

Energy supplied to the producer:—		%
Heat of combustion of the coke ..	96.97	
Heat in steam supplied under the grate ..	3.03	
	100.00	
Energy subtracted from producer:—		%
Calorific value of gas ..	79.13	
Sensible heat in dry gas ..	0.46	
Latent and sensible heat in moisture in gas ..	1.80	
Heat used in evaporating feed water ..	15.56	
Heat in unburnt combustible matter in clinker ..	0.71	
Heat in unburnt combustible matter in flue dust ..	0.20	
	97.86	
Heat lost by radiation and conduction (by difference) ..	2.14	
	100.00	

The percentage composition of the producer gas was:—CO₂=3.65, O₂=0.2, CO=29.12, H₂=9.88, CH₄=0.2, N₂=56.95. The thermal balance sheet for the ovens showed that the heat doing useful work in the ovens amounted to 71.1% of the heat of combustion of the coke used in the producers, whereas the producer gas itself contained 81.6% of the heat of combustion of the coke used in its production. The difference represents heat lost in the waste gases and by radiation from the ovens.

—T. F. E. R.

Gas economics, with special regard to carbonisation and the treatment and disposal of residual products. J. Dickson. Scottish Junior Gas Assoc. Gas J., 1918, 144, 187–189.

THE author deals with the steaming of coal charges during carbonisation and the necessary precautions to be observed in order to obtain success. By steaming vertical retorts of the continuous-intermittent type a make of 16,193 cub. ft. gas per ton has been obtained. After oil washing the gas had a calorific value of 450–460 B.Th.U. and the composition H₂ 50.8, CH₄ 19.7, unsaturated hydrocarbons 2.2, CO 14.1, O₂ 0.8, CO₂ 5.6, and N₂ 6.8%. The coal passes the pasty stage sooner with steaming. A survey is given of some recent progress in gas works in coke manufacture, boiler firing and fuel economy, ammonia recovery, tar dehydration, and benzol recovery.—T. F. E. R.

Naphthalene: Estimation of — in coal gas. H. G. Colman. Gas J., 1918, 144, 231–232.

THE author describes additional precautions or modified methods to be employed in estimating naphthalene in coal gas by the method previously described by Colman and Smith (this J., 1900, 128). The gas is passed through a series of four wash-bottles, the first of glass throughout containing a 10% solution of citric acid to retain any ammonia in the gas. The second wash-bottle contains 100 c.c. of N/20 picric acid, the third 50 c.c. of the same solution, and the last is left empty to retain spray. The gas must have no access to indiarubber during or prior to its passage through the train (see this J., 1900, 813). The picric acid solution is standardised with N/10 caustic soda solution, using lacmoid or phenolphthalein as indicator. The gas (about 10 cub. ft.) is passed through the apparatus at a rate not exceeding 1 cub. ft. per hour, the volume being corrected to 60° F. (15.5° C.), and 30" pressure. After passage of the gas, the contents of the third and fourth bottles of the train are washed into the second bottle, which is then closed by a tight-fitting rubber stopper fitted with glass stopcock or glass device answering the same purpose. The wash-bottle is evacuated until the naphthalene picrate rises to the surface. The stopcock is closed and the contents of the bottle heated to boiling with occasional shaking, and then allowed to cool with occasional shaking. The volume of the cold mixture is measured, the naphthalene picrate is separated by filtration through a dry filter paper, the first few c.c. of the filtrate being rejected, and 100 c.c. of the filtrate is titrated with N/10 NaOH solution. If *v* represents the difference between the volume of N/10 NaOH required to neutralise the total volume of N/20 picric acid solution originally taken, and that required for the neutralisation of the total volume of picric acid solution after heating and filtering, then: Grains of naphthalene per 100 cub. ft. = $\frac{v \times 19.75}{\text{volume of gas passed}}$.

—J. S. G. T.

Gas; Relative efficiency in use of different grades and compositions of —. First Report of Research Sub-Committee appointed by the Gas Investigation Committee, Inst. of Gas Eng., 9.5.18, with supplementary matter 9.8.18. Gas J., 1918, 144, 235–249.

The report deals with the relative efficiencies of various grades of gas in existing appliances for use with gas, no adjustments additional to those furnished by the makers being, in general, introduced.

Ring burners. Gases varying in calorific value from 530 B.Th.U. gross and 480 net to 281 B.Th.U. gross and 214 net were employed. The experiments with ring burners are the most complete of the series. The following conclusions, amongst others, are drawn: (a) Unless interfered with by very poor aeration or too close proximity of the containing vessel, within wide limits, the efficiency of a boiling ring is almost independent of the rate at which the gas is burnt. (b) Flame contact is essential for high efficiency. (c) The distance of the bottom of the vessel, in which water is being boiled, from the burner requires careful adjustment in order to secure maximum efficiency. (d) Provided suitable adjustments are made, the efficiency is practically independent of the composition, content of inert gases, or calorific value of the gas. (e) A wide variation in grade or composition of gas can be made with reference to other uses, without impairing the efficiency of ring burners now in use.

Upright low-pressure incandescence lighting burners. Experiments were carried out with gases varying in calorific value from 615 B.Th.U. gross, 552 net, to 314 B.Th.U. gross, 285 net. The candle power developed in a horizontal direction was alone measured. The different consumptions of the burner were adjusted by varying the pressure at the injector of the burner. The main conclusions derived are:—(a) With gases of about 450 B.Th.U. gross and below, the control possible to obtain by varying the consumption and aeration was not sufficient to give satisfactory illumination. (b) With the burner used, a gas of about 550 B.Th.U. gross maximum to 500 B.Th.U. net minimum gave the best performance, both as regards efficiency and total illumination. (c) The maximum attainable illumination was found at about 525 B.Th.U. gross.

Gas fires. The whole series of experiments with gas fires is not yet complete. The calorific value of the gases employed ranged from 559 B.Th.U. gross, 503 net, to 385 B.Th.U. gross, 347 net. The same fire was not used throughout the series of tests. The main conclusions are as follows:—(a) With each gas fire, there is a certain consumption which for the gas used gives the maximum radiant efficiency. (b) If the radiants are heated to less than half their height the efficiency suffers severely. (c) Existing gas fires vary very considerably in their ability to adapt themselves to gases of different grades.—J. S. G. T.

Motor fuels; Valuation of —. H. Moore, Automobile Eng., Sep., 1918, 245–248.

The methods at present in vogue for the analysis of motor spirits are not fully satisfactory for the testing of mixed fuels such as will probably be extensively used in the future. The conditions existing in the engine and in the carburettor through which the fuels have to pass are the main factors in deciding the tests to which a motor spirit should be subjected. *Specific gravity* has little value as an indication of the quality of a motor spirit. The *viscosity* of all common fuels is very small, but this value may become important with future fuels. Heavy oils for Diesel engines may

require suitable preheating to maintain the viscosity within reasonable limits. The *cold test* is important for fuel mixtures containing solid hydrocarbons in solution. For aero-engine fuels it is essential that the temperature at which solids separate shall be very low. The *coke test* consists in volatilising the fuel in a platinum crucible and coking any residue remaining. Some of the heavier coal-tar distillates present in mixed fuels sold as “substitutes” yield appreciable quantities of coke. The *fractional distillation test* gives considerable information as to the ingredients present in a fuel mixture. *Latent heat of vaporisation* is an indication of the cooling effect produced in the carburettor, and of the desirability or otherwise of hot air intake. *Iodine and bromine values* give information as to the method of preparation of petroleum spirits, but are not a direct indication of the behaviour of a fuel in the engine. The *ultimate analysis* indicates the nature of the products present in the fuel, and allows of the calorific value and the weight of air required for combustion being calculated. The *temperature of spontaneous ignition* of a fuel (this J., 1917, 109–112) determines the limits of compression pressure which may be employed. When these limits are exceeded, pre-ignition takes place, and knocking and inefficient running result. The most careful consideration is necessary in preparing mixed fuels to ensure that the mixtures will stand normal compression pressures without pre-igniting. *Vapour pressure* determinations give direct information as to the probable behaviour of fuels as regards easy starting and “flexibility.” Benzol and good quality petrols have high vapour pressures, and the former also possesses the property of raising the ignition point of mixtures. It is therefore advantageous to mix benzol with heavy petroleum fuels (which, consisting mainly of aliphatic hydrocarbons, have low ignition points), and to employ light petrol for “livening” heavy fuels of coal-tar origin, such as solvent naphtha, which consists mainly of aromatic hydrocarbons (largely xytol) and has a comparatively high ignition point. The *explosive range* must be considered in adjusting carburetting devices, so that the throttle scale may fall within the range, and the lower limit requires consideration in connection with vapour pressure for fuels, such as alcohol, which are only explosive in mixtures containing comparatively high percentages. *Velocity of flame propagation* is not easy to determine; it affects the correct angle of spark advance at any given speed. Fuels which possess slow speeds of flame propagation, and, therefore, require greater angles of spark advance, can withstand slightly higher compression pressures than fuels of equal ignition point but possessing higher velocities of flame propagation. *Calorific values* (per weight) of motor spirits of any particular class do not vary greatly.—T. St.

Paraffin wax; Heat of fusion of —. G. von Kozicki and S. von Pilat. Chem. Umschau, 1917, 71. Chem.-Zeit., 1918, 42, Rep., 147.

The heat of fusion of paraffin wax was determined by the lowering of the solidifying point on adding a compound (naphthalene, dimethylaniline, phenanthraquinone) of known molecular weight. It was found that the latent heat of fusion ranges from 38.9 to 43.9, increasing with rise of specific gravity, solidifying point, and molecular weight.

Hydraulic separation. Draper. See I.

Gas purification masses. Müller. See VII.

PATENTS.

Liquid fuel burners. Burdons, Ltd., W. M. and M. M. Burdon, Bellshill, Lanark. Eng. Pat. 119,376, 18.1.18. (Appl. 1042/18.)

THE air supply for the burner passes through a pipe in the discharge flue of the furnace to preheat it to a temperature above the flash point of the oil, and thence to the rear of the burner nozzle where it is rotated and agitated by a helix and a small rotary fan. The front of the nozzle contains a short concentric inner tube into which a supply of heavy pitch or tar oil, or tar, is drawn by the air suction. The oil is vaporised and mixed with air in the central tube, and air passes also through the surrounding annular space. The nozzle is slightly smaller at the outlet, so that the inner conical jet of combustible mixture, and the outer hollow conical jet of air impinge at a point in front of the nozzle. The air supply pipe may be provided with an expansion joint, and may be replaced by two pipes to provide a greater heating surface. Modified forms of burner nozzles are described and also the application of the apparatus for heating a gas producer.—W. F. F.

Alcohol; Solidified —. A. Strobl, New York. U.S. Pat. 1,277,149, 27.8.18. Appl., 20.7.15.

SOLIDIFIED alcohol burning without soot is composed of ethyl alcohol 60 parts, methyl alcohol 40 parts, and sodium stearate 2–3 parts.—W. F. F.

Chamber ovens or retorts for producing gas and coke or fuel; Heating flues of —. C. W. Simpson, Leeds. Eng. Pat. 119,413, 12.4.18. (Appl. 6230/18.)

INCLINED gas retorts are arranged parallel to one another in a setting, and are heated by inverted U-shaped flues arranged between each pair of retorts. One limb of each flue is provided with a gas burner at the bottom, and all the burners between one pair of retorts are fed by an inclined gas conduit parallel to the retorts below the flues, so that the gas is preheated. All such gas conduits are supplied by a transverse flue in front of the setting. Preheated air is supplied to each burner from an inclined air flue parallel to the inclined gas conduit, and the combustion products pass in reverse direction through return flues parallel and adjacent to the gas conduit and air flue, and thence to a regenerator. An inspection opening is provided at the top of each of the inverted U-shaped flues, through which the burners, which are fitted with renewable and interchangeable nozzles, are accessible.—W. F. F.

Coal; Calcining — at high temperatures [in an electric furnace]. W. Dyrssen, New York. U.S. Pat. 1,277,707, 3.9.18. Appl., 27.5.18.

COAL is fed continuously downwards through an electric furnace from which air is excluded, the electrodes being arranged at an angle with one another converging towards the centre. The electrodes are adjusted longitudinally to vary the length of the arc, so that the voltage required for varying conditions of the charge is approximately constant.—W. F. F.

Illuminating gas; Furnace for the production of — in vertical retorts or chambers. Chamottefabrik Thonberg A.-G., Thonberg. Ger. Pat. 307,267, 19.2.16.

THE charge of a vertical retort for the production of illuminating gas is dropped, when evolution of gas is complete, into an extension of the retort built in the furnace walls and of sufficient size to

receive the whole of the charge. The hot coke heats up the surrounding brick work in which are passages for the air used in the furnace, and is then drawn off into a receiver through a gas-tight device consisting of a rotating drum with one or more openings.—L. A. C.

Ammonia recovery producer gas process and apparatus therefor. A. H. Lynn and N. E. Rambush. London. Eng. Pat. 119,049, 13.6.17. (Appl. 8461/17.)

HOT producer gas is passed through a washer to remove dust and cool it to a temperature not materially below 80° C., and is then passed upwards through a tubular reflux condenser. The admission zone of the condenser is kept at about 80° C., if necessary by external means, and the discharge zone of the condenser is kept at about 40° C. so that steam and tar are condensed and the ammonia passes out with the gases. The ammonia may then be absorbed by acid at normal temperature. In a modification a number of superposed tubular condensers may be used, having a free space for mixing the gases, between the tube-plates of each pair. The gas passes through the tubes, which are surrounded by films of cooling water. The heat transferred to the cooling water may be recovered for preheating the air blast for the producer, by passing the air around the tubes. Any ammonia contained in the condensed water and tar may be recovered by heating it with or without lime or other alkali.—W. F. F.

Gas producers. A. H. Lynn and N. E. Rambush. London. Eng. Pat. 119,207, 17.5.18. (Appl. 8258/18.)

IN a gas producer having a revolving grate, in which the portion on which the charge rests is provided with inclined helical lifting surfaces alternating with abrupt shoulders of considerable depth (see Eng. Pat. 15,467 of 1915; this J., 1917, 379), the shoulders are made sloping in a series of steps so as to make the descent of the charge less abrupt. The air blast is delivered through the spaces between the steps, which may be formed of a series of interlocked bars.—W. F. F.

Hydrocarbon oils; Process of treating — and the product. T. Payne, Detroit, Mich., U.S.A. Eng. Pat. 119,066, 6.9.17. (Appl. 12,802/17.)

COMMERCIAL grades of kerosene, coal oil, etc., are cooled under increasing pressure, and at successive stages saturated with different combustible gases at the same pressure and temperature as the oil. The temperature and pressure are then restored to about atmospheric. The product can be utilised in place of gasoline in internal combustion engines. For example, kerosene may be caused to absorb, in this manner, in successive stages (1) about 5 vols. of coal gas at 0° C. and 6 atmospheres pressure, (2) about 8 vols. of Pintsch gas at -18° C. and 8 atmospheres, or about 3 vols. of acetylene at -26° C. and 12 atmospheres, and (3) 2 vols. of hydrogen at -35° C. and 15 atmospheres.—T. St.

Oil gas; Apparatus for producing —. W. Pickard, Rochdale, and D. R. Dobson, Bolton, Lancs. Eng. Pat. 119,399, 15.3.18. (Appl. 4588/18.)

AN inner chamber, *a*, containing crude liquid hydrocarbon is surrounded by a chamber, *b*, containing water acidulated with sulphuric acid. A heating coil, *c*, is fed by the pipe, *c*¹, and exhausts into the central pipe, *d*, chamber, *k*, and discharge pipe, *k*¹. Hydrocarbon vapour and steam generated by means of the burner, *f*, pass upwards through two layers of iron filings, *g*, *i*, supported on per-

forated trays, *h, j*, and then through a layer, *l*, of finely powdered charcoal and iron filings maintained at a red heat by a burner, *m*. The resulting

permanent gas of low calorific value passes through porcelain tubes, *k²*, to the collecting chamber, *n*, and thence for use as required.—W. F. F.

Hydrocarbons; Process of producing — H. H. Mandle, New York. Eng. Pat. 119,284, 27.9.17. (Appl. 13,955/17.)

HEAVY hydrocarbon oil such as crude petroleum, distillate, or residue, is mixed with water in any desired proportion by means of pumps drawing from separate tanks, the stroke of one of the pumps being variable. The mixture is sprayed into the upper end of a tortuous cracking tube in a heated chamber, and passes over a catalyst consisting of a packing of woven nickel-chromium-steel wire at the lower end of the tube. The cracked vapour is then passed through condenser pipes in the oil supply tank, whereby the oil is preheated and part of the vapour is condensed. The condensed liquid is collected in another tank and returned to the main tank for further treatment. The uncondensed vapour is then passed through a similar condenser in the water supply tank, whereby the water is preheated and a further portion of the vapour condensed. The uncondensed gas passes to a storage reservoir. The products include gasoline, benzene, toluene, and other light aromatic hydrocarbons.—W. F. F.

Hydrocarbon oils; Method of decomposing — A. E. Alexander, London. From A. R. Adams, New York. Eng. Pat. 119,485, 5.7.17. (Appl. 9713/17.)

WITHIN a furnace are three superimposed coils of piping. Water is forced through the top coil, and the steam generated is passed into the bottom of a closed tank containing hydrocarbon oil, thereby forming an emulsion of oil and steam which is forced by air pressure upwards through the middle or "subgenerator" coil, on leaving which it passes down a pipe outside the furnace, through an

atomiser, and into the upper end of the lowest or "generator" coil. At the lower, outlet end of this coil there is a metallic catalyst (preferably platinum, palladium, or nickel) in the form of a spirally wound coil of wire gradually decreasing in diameter until it merges into a point directed reversely to the flow of the gases. By the action of the catalyst the water vapour is decomposed and the hydrogen formed, together with free hydrogen produced by decomposition of the oil, is caused to combine with hydrocarbons, forming compounds of low boiling point. The apparatus may also include a condenser, a separator, a scrubber, and suitable means for storing the liquid and gaseous products. When it is desired to produce a maximum of fixed gas, the generator is heated to about 1600° F. (about 875° C.) and the pressure is reduced to a minimum; when a maximum of hydrocarbon compounds of low boiling point is required, the pressure is increased, preferably to about 250 lb. per sq. in., and the temperature reduced to about 1100° F. (about 595° C.). For heating the furnace, a portion of the emulsion of oil and steam is forced out of the storage tank into a burner of special construction. The mixture enters the burner through a circular coil of pipe heated by the flames of the burner. The vapours generated are led into an expansion box and then to the burner tip. Air for combustion is also admitted to the burner tip. At the outlet end of the circular coil of pipe and within the expansion chamber are coils of catalytic metal similar in construction to and for the same purpose as those at the outlet end of the generator coil.—L. A. C.

Oil-distilling apparatus. J. B. Edwards, Jersey City. Assignor to Tide Water Oil Co., Bayonne, N.J. U.S. Pat. 1,277,884, 3.9.18. Appl., 19.9.16.

IN the upper part of a pressure still for the pressure cracking of petroleum or its higher boiling fractions is a disc valve mounted in a vertical guide. The valve is normally held open by suitable means, which can be released by a device operable at a distance from the system, the pressure within the still then forcing the valve against the outlet.

—L. A. C.

Paraffin; Extracting — from oils. J. S. Hussey, Martinez, Cal. U.S. Pat. 1,277,935, 3.9.18. Appl., 22.1.17.

MINERAL oil is introduced into a vertical cylinder in which there is a hollow rotating shaft fitted with a hollow arm provided with a number of openings near the bottom of the vessel, and a "gathering or skimming" arm at the surface of the oil. Air is forced through the shaft into the hollow arm and through the openings into the oil in the form of small bubbles, around which the paraffin collects and is carried to the surface, whence it is removed by the upper arm.—L. A. C.

Hydrocarbons [paraffin]; Process for separating — [from still residues]. R. R. Rosenbaum, Chicago, Ill. U.S. Pat. 1,278,023, 3.9.18. Appl., 13.12.17.

TO separate paraffin from the residue of the distillation of crude oil, the residue is heated and intimately mixed with finely divided absorbent material. The mixture is then cooled by agitation in contact with cooling surfaces and treated with a solvent which does not dissolve the paraffin but dissolves other hydrocarbons present. After removing the solution from the solid residue, the paraffin is separated from the porous absorbent material.—L. A. C.

Petroleum and other hydrocarbon oils [; Refining —]. H. W. Knottenbelt, Brussels. U.S. Pat. 1,277,605, 3.9.18. Appl., 3.7.16.

Hydrocarbon materials; Apparatus for the extraction of — [from shale]. A. M. Boyle, Assignor to Crane Shale Oil Corporation, Reno, Nev. U.S. Pat. 1,276,866, 27.8.18. Appl., 29.12.17.

A VERTICAL retort for treating shale is heated by means of a steam jacket and is fitted with a vertical rotating screw agitator which raises the shale in the centre of the retort and allows it to fall down the space between the agitator and the walls. Means are provided for releasing steam confined within the peripheral sweep of the agitator, and for drawing off the gases and vapours from the top of the retort. Shale is fed into a supply container from the bottom of which it is conveyed into the retort along a tubular screw conveyor inclined upwards, the upper end of the conveyor leading into a vertical shoot down which the shale passes into the retort.—L. A. C.

Hydrocarbon materials; Process of extracting — from shale and similar earthy material. A. G. Crane, Assignor to Crane Shale Oil Corporation, Reno, Nev. U.S. Pat. 1,276,879, 27.8.18. Appl., 4.10.17.

FINELY-DIVIDED shale or other earthy material is mixed with a neutral, granular, non-absorbent material (e.g., sand) and while thoroughly agitated, treated with dry steam in a suitable container. The mixture is then conveyed to another container in which it is heated to a higher temperature and under a pressure greater than that of the atmosphere. The vapours generated at each stage are withdrawn and condensed.—L. A. C.

Lignite, peat, wood, etc.; Distillation of —. Bertz Ges.m.b.H., Munich. Ger. Pat. 306,956, 21.3.16.

THE material is partially dried (to a moisture content of 10 to 20%) by a counter current of moderately moist air prepared by mixing the waste heating gases arising from the furnace with cold air. Peat and other very moist fuels are first air dried to a moisture content of about 50%.—L. A. C.

III.—TAR AND TAR PRODUCTS.

Phenol and the cresols; Compounds of — with pyridine. H. F. W. Skirrow and T. V. Binmore. J. Amer. Chem. Soc., 1918, 40, 1431—1442.

THE effect of excess of phenol and excess of pyridine on the dissociation of pyridine phenoxide, postulated as $C_6H_5OH.C_5H_5N \rightleftharpoons C_6H_5OH + C_5H_5N$, has been studied by the cryoscopic method and it

has been found that phenol depresses the dissociation much more strongly than does pyridine. The dominant equilibrium might therefore be $(C_6H_5OH)_2.C_5H_5N \rightleftharpoons 2C_6H_5OH + C_5H_5N$, but a study of this dissociation on similar lines showed that the effect of excess of phenol on the apparent dissociation was only greater than that of excess of pyridine with comparatively high additions of these. An explanation of these results and of the extraction results obtained previously (Hatcher and Skirrow; this J., 1918, 51 A) is based on the following equilibria: $C_6H_5OH.C_5H_5N \rightleftharpoons C_6H_5OH + C_5H_5N$ and $C_6H_5OH.C_5H_5N + C_6H_5OH \rightleftharpoons (C_6H_5OH)_2.C_5H_5N$. It is shown that the difference between the effect of addition of excess of phenol and of excess of pyridine on the extraction experiments tends to disappear as the dilution of the benzene solution is increased.—H. W.

Chlorinated toluene; Rapid analysis of mixtures of —. H. A. Lubs and A. B. Clark. J. Amer. Chem. Soc., 1918, 40, 1449—1453.

THE sample (about 0.5 gm.) is placed in a sealed tube with water (10 c.c.) and briskly shaken in a bath of boiling water for two hours; the contents of the tube are washed into a small assay flask, and the tube is rinsed with water (free from carbon dioxide) and then with alcohol if any benzoic acid remains. The solution is then titrated with alkali in the presence of thymolsulphophthalein according to the authors' method (see page 718 A). The percentage of benzotrichloride (x) is calculated from the benzoic acid formed; the percentages of benzal chloride (y) and benzyl chloride (z) are derived from the following relations: $x + y + z = 100$; $0.545x + 0.434y + 0.281z = \% \text{ side chain chlorine}$. The method is very suitable for plant control work and, if certain precautions are taken, will give a high degree of accuracy.—H. W.

*Toluene-*o*- and -*p*-sulphonamides; Freezing point curve of mixtures of —. Composition of mixtures of toluene-*o*- and -*p*-sulphonic acids.* P. V. McKie. Chem. Soc. Trans., 1918, 113, 799—803.

THE estimation of the relative amounts of toluene-*o*- and -*p*-sulphonic acids in a mixture of the two acids cannot be satisfactorily performed by means of the freezing point curve of the mixed sulphonyl chlorides (Holleman and Caland, this J., 1911, 1202) for several reasons, particularly on account of the flatness of the curve in the eutectic region. The fusion curve of the sulphonamides, however, is satisfactory. It lies within a convenient range of temperature, namely 110°—156° C., and the eutectic point (110.25° C.; 61.25% of the *p*-sulphonamide) is extremely sharply defined. The melting points, not the freezing points, of the mixtures were determined.—C. S.

Carbonisation of coal. Savage. See IIa.

Naphthalene in gas. Colman. See IIa.

PATENTS.

Aromatic hydrocarbons; Process of oxidising — and the lower oxidation products thereof. Process of oxidising aromatic hydrocarbons having a plurality of side chains, or consisting of a plurality of rings and the lower oxidation products of such hydrocarbons. The Seldon Co., Pittsburgh, Pa., and H. D. Gibbs, Cherrydale, Va., U.S.A. Eng. Pats. (A) 119,517, and (B) 119,518, 1.10.17. (Appls. 14,150 and 14,151/17.)

AROMATIC hydrocarbons containing one or more side chains or consisting of a number of rings are oxidised by treatment in the form of vapour at a suitable temperature with an oxygen-containing

gas (e.g. air) in the presence of a catalyst comprising an oxide or mixture of oxides of metals of the fifth or sixth group of the periodic classification, i.e. antimony, bismuth, chromium, tungsten, uranium, or, preferably, molybdenum, and vanadium. The oxides may be in a coarse or fine state of division, and the gas and vapour mixture may be passed over or through the catalyst. In the case of hydrocarbons containing one side chain, the temperature employed lies between 200° and 500° C. (preferably between 350° and 450° C.); in the case of hydrocarbons containing a number of side chains or consisting of a number of rings, the temperature varies between 250° and 600° C. The quantity of oxygen employed should be, preferably, twice that required by theory. Examples: (A) Toluene vapour mixed with air is passed over vanadium oxide (V_2O_5) between 350° and 450° C., and the resulting mixture, consisting chiefly of benzaldehyde, together with some benzoic acid, unconverted toluene, and water, is separated by suitable means; (B) a mixture of naphthalene vapour and air is passed over vanadium oxide at 350°–550° C. (preferably about 450° C.), or over molybdenum oxide (MoO_3) at about 500° C., resulting in the formation of phthalic anhydride, phthalic acid, 1,4-naphthoquinone, benzoic acid, and water; oxidation of xylene vapour in a similar manner results in the formation of methylbenzaldehydes, phthalaldehydes, benzenedicarboxylic acids, toluic acids, benzoic acid, and benzaldehyde; oxidation of anthracene vapour (preferably at about 500° C.) results mainly in the formation of anthraquinone. —L. A. C.

Hydrocarbons. Eng. Pat. 119,284. See II A.

IV.—COLOURING MATTERS AND DYES.

Fuchsine synthesis; Explanation of Heumann's — H. E. Fierz and H. Koechlin. *Helv. Chim. Acta*, 1918, 1, 218–226.

In the original Heumann reaction (Ger. Pats. 66,511 and 68,976), in which carbon tetrachloride, aluminium chloride, and a tertiary amine, for example dimethylaniline, react to produce Crystal Violet or an analogous product, the authors claim that the initial product of the reaction is the ketochloride, $CCl_3[C_6H_4.N(CH_3)_2]$, because a small quantity of Michler's ketone is obtained by adding the reaction product to ice-water. When acetanilide is used in place of dimethylaniline, a 60% yield of 4,4'-diaminobenzophenone is obtained after hydrolysing the product formed by the addition of ice-water. In a similar way *o*-chloroacetanilide yields 3,3'-dichloro-4,4'-diaminobenzophenone and dimethyl-*m*-toluidine yields 2,2'-dimethyl-4,4'-tetramethyldiaminobenzophenone. (See also J. Chem. Soc., Dec., 1918.)—C. S.

Quinonoid dyes; Formulation of so-called — H. E. Fierz and H. Koechlin. *Helv. Chim. Acta*, 1918, 1, 210–218.

The authors propose to apply, with certain modifications, Werner's views of the structure of inorganic substances to quinonoid dyes and to formulate these as complex compounds. Thus fuchsine chloride is represented by the formula, $[(NH_2.C_6H_4)_3(C)]Cl$, and similar formulae are proposed for dyes of the diphenylmethane, azine, thiazine, oxazine, and xanthene classes. (See also J. Chem. Soc., Dec., 1918.)—C. S.

Sulphur dyestuffs; Determination of sulphur that produces sulphuric acid in — W. Zänker and K. Schnabel. *Färber-Zeit.*, 1918, 29, 26–29.

SULPHUR dyestuffs, when exposed to the air in a finely divided, moist condition, become acid with sulphuric acid. The rate of formation of acid is

increased by rise of temperature. In presence of alkali the formation of acid is favoured and reaction accelerated. Various dyestuffs were tested both in the commercial form and after purification by dissolving 1 grm. of dyestuff and 2 grms. of pure sodium sulphide in 250 c.c. of water, boiling for a short period, pouring the solution into 3 litres of water acidified with acetic acid, allowing to settle, washing the residue six times by decantation with water acidified with acetic acid, collecting the dyestuff on a hardened filter, and drying at 100° C. For the estimation of the acid the dyestuff was mixed with 50 c.c. of N/10 caustic soda, evaporated to dryness, and heated for one hour at 110° C. to 120° C. The labile sulphur was thus converted into sulphuric acid, the amount of which was determined by back titration, using as indicator phenolphthalein, or litmus upon writing paper. The following table shows the results obtained:—

Dyestuff	Percentage of pure dyestuff in commercial article	Percentage of sulphur giving sulphuric acid		Percentage of sulphuric acid formed	
		Pure dye	Commercial dye	Pure dye	Commercial dye
Thioxin Black G O.O.O.	69.62	9.43	6.56	28.93	20.14
Sulphuroil Black ...	46.2	13.09	6.05	40.14	18.55
Katigene Deep Black.					
Immedial Brilliant	56.98	11.07	6.31	33.96	19.35
Carbon F.G. ...	82.52	8.86	7.32	27.19	22.44
Immedial Black N.N.G.	52.72	12.81	6.75	39.29	20.72
Katigene Black F.G. ...	39.32	17.91	7.03	54.95	21.56
Katigene Brilliant					
Black F.G. ...	70.66	9.60	6.78	29.46	20.82

These figures do not show the sulphuric acid produced on dyed materials, but simply the acid produced under the above conditions.—L. L. L.

Morindone. J. L. Simonsen. *Chem. Soc. Trans.*, 1918, 113, 766–774.

THE glucoside, morindin, has been extracted from the root bark of *Morinda citrifolia* and very carefully purified. It has the composition, $C_{26}H_{38}O_{14}$, and from its properties and those of its acetyl derivative there would appear to be no difference between morindin obtained from *M. citrifolia* and that from *M. umbellata* (compare Perkin and Hummel, this J., 1894, 940, 1054; Oesterle and Tisza, 1908, 441; Perkin, 1908, 766). Morindone, obtained by hydrolysis of the glucoside, appears to be either a hydroxymethylanthranufin or a hydroxymethylchrysazin.—C. S.

Pyrrrole Blacks. A. Angeli. *Atti R. Accad. Lincei*, 1918, 27, I., 209–212.

LIKE hydrogen peroxide in acetic acid (see this J., 1917, 210), most oxidising agents convert pyrrole into highly coloured products, mostly black or brown, some of these being readily soluble in alkali and some insoluble. Thus, the action of potassium bichromate on an acetic acid solution of pyrrole produces a black precipitate, which may be produced on a cotton fabric and is very fast to soap and light. This colouring matter is apparently a chromium lake.—T. H. P.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Vegetable fibrous materials; Scheme for the analytical investigation of — and the cellulose prepared from them. C. G. Schwalbe. *Verein deut. Chem.*, Sep., 1918. *Z. angew. Chem.*, 1918, 31, 193–194.

THE time is ripe for a coördinated re-investigation on a uniform basis of all the standard raw

materials of the textile and cellulose industries, in order that the proximate composition of these may be definitely fixed, the variations due to environment, etc. defined, and the results utilised for the classification and evaluation of new or little known materials. The author discusses the question of the selection of the analytical "constants" of most general significance and of the standardisation of methods and apparatus. These questions should be settled by a committee of recognised standing, and data should be accumulated on the agreed basis. The scheme of analysis proposed by Cross and Bevan and utilised by other investigators is regarded as not fully adapted to the light of modern knowledge: it is considered to be unnecessarily long and to contain factors of undetermined significance. The abbreviated scheme recommended by the author comprises determinations of ash, moisture, fat, wax and resin, cellulose, furfural, methylfurfural, and methoxyl. The pentosans are satisfactorily represented by the furfural value, but certain standardisation of methods and apparatus is required to ensure concordant results. The lignin may be taken to be represented by the methoxyl value, but it is possible that this requires correction by the results found for methylfurfural which is supposed to represent methylpentosans.

—J. F. B.

Celluloid; Analysis of —. A. Hervé. Caoutchouc et Gutta Percha, 1918, 15, 9601—9604.

The rasped celluloid may be extracted in a Soxhlet apparatus, preferably with chloroform, and the camphor determined by difference. The nitrocellulose residue, however, obstinately retains some of the solvent, even after drying to constant weight, and a correction should be made for the retained chloroform by saponification of the residue by alcoholic potassium hydroxide and determination of the chloride produced. Alternatively the camphor may be determined by the cryoscopic method in benzene solution. For the extraction of the camphor, 2–5 grms. of the celluloid, in small pieces about 1 mm. thick, is placed in a distillation flask with 200 c.c. of water and 2–3.5 grms. of potassium hydroxide. The camphor is distilled over and solidifies in the condenser: the operation is generally complete when 150 c.c. of distillate has passed over. The water is exhausted by shaking twice with 5 c.c. of pure benzene. This benzene is used for washing down the condenser, and is collected together with five other washings in a flask of about 100 c.c. The benzene solution of camphor is dried by anhydrous copper sulphate and filtered into a 50 c.c. flask. The filter is washed with dry benzene and the solution made up to the mark. The cryoscopic apparatus used is a modification of that of Raoult, with a Beckmann thermometer graduated in 0.01° C. Cooling is effected by the evaporation of carbon bisulphide in a current of air, and the tube containing the camphor solution is placed in an intermediate jacket containing alcohol. The camphor solution is stirred during the operation and the thermometer is read with a lens. The solution is slowly supercooled, a crystal of pure benzene is dropped in, and the point to which the thermometer rises and then remains constant for one minute during solidification is taken as the freezing point. The result is calculated from a table prepared from observations with solutions containing known quantities of pure camphor. The accuracy of the method has been verified, and with the lens the thermometer can be read to 0.001° C. Methylacetanilide (mannol) in admixture with acetanilide may be estimated cryoscopically in the same way, using pure aniline as the solvent.—J. F. B.

Celluloid; Stabilisation of [nitrocellulose for manufacture of] —. A. Colassi. Caoutchouc et Gutta Percha, 1918, 15, 9604—9605.

NITROCELLULOSE intended for the manufacture of celluloid should undergo a process of stabilisation with hot water if subsequent troubles are to be avoided, since even the most thorough washing with cold water is not sufficient to eliminate the unstable forms of nitrocellulose of a low degree of nitration. The material on coming from the hydroextractors or nitrating pots is ground in a hollander, and is afterwards repeatedly washed with successive changes of hot water until it is sufficiently purified to pass the heat test for stability. Two grms. of the nitrocellulose is placed in a test-tube and heated in a paraffin bath at 130° C.; a satisfactory material should not decompose with formation of brown fumes in less than an hour at this temperature. The occurrence of white points in celluloid is sometimes due to the presence of particles of nitrocellulose of a high degree of nitration; these white points are insoluble in alcohol and camphor, but may be recognised by their gelatinisation in acetone.

—J. F. B.

Cellulose and nitrocellulose. Hervé. Sec XXII.

PATENTS.

Woven fabric; Material for — and process of manufacturing it [from palm leaves]. K. Miyake, Tokyo, Japan. Eng. Pat. 119,428, 7.6.18. (Appl. 9422/18.)

The fresh leaves of the coconut palm are boiled in water for a short time, then torn apart into upper and lower halves. The halves are then torn into strips or bands of suitable width, which are boiled for 1–2 hours in a 5–8% solution of sodium carbonate. The material is washed and steeped in a bleaching solution containing 1–3 lb. of sodium peroxide, 1–2 lb. of potassium oxalate, and 50–100 grms. of sulphuric acid to 100 lb. of water. The treated strips roll up on drying, and form smooth, semi-transparent threads suitable for weaving into various articles, e.g. hats, mats, bags, etc.

—J. F. B.

Textile product [; Water-repellent —] and process of making same. W. L. Franck, Philadelphia, Pa. U.S. Pat. 1,277,057, 27.8.18. Appl., 9.3.17.

A soft, pliable, water-repellent material is produced by treating textile fibre with a mixture of chromium sesquioxide and glucose. The bath is prepared by dissolving 4 parts of sodium bichromate in water and adding 8 parts of commercial hydrochloric acid, 2 of glucose, 3 of "sal soda" (sodium carbonate), 2 of sodium thiosulphate, and 2 of sodium sulphite.

—J. F. B.

Yucca and the like; Process of preparing and extracting vegetable fibre from —. A. G. Brown, Assignor to Yusi Fibre Co., Los Angeles, Cal. U.S. Pat. 1,277,185, 27.8.18. Appl., 24.12.17.

GREEN yucca leaves are passed between crushing rollers, and the crushed material is boiled, passed between corrugated rollers, then between differential smooth rollers, and the soft wet material treated in a scutching machine.—J. F. B.

Fabric; Soil-proof — and process of making the same. L. J. Cavanaugh, Swampscott, Mass. U.S. Pat. 1,277,695, 3.9.18. Appl., 20.7.17.

TEXTILE fabric is first saturated with a fixing agent, e.g. a solution of a metallic salt, then dried, impreg-

nated with a highly volatile non-solvent of dissolved cellulose, e.g. petroleum spirit mixed with a small proportion of oil, and finally coated with a preparation of dissolved cellulose.—J. F. B.

Wool-scouring liquors; Recovery of potassium and sodium compounds, fats, and other valuable ingredients from —. F. E. Underwood and B. F. Illston, Jamestown, N.Y. U.S. Pat. 1,277,784, 3.9.18. Appl., 1.6.17.

WOOL-SCOURING liquor is treated with an alkaline-earth salt, such as magnesium sulphate, and heated at about 350° under a pressure of about 125 lb. per sq. in., in order to separate all the fats in the form of insoluble soaps or in conjunction with such soaps. The liquid is separated and evaporated for the recovery of potassium and sodium salts, and the insoluble soap is treated with an acid to liberate the fat and regenerate the magnesium sulphate for further use.—J. F. B.

Celluloid; Manufacture of uninflamable —. H. Dreyfus, Basle, Switzerland. Eng. Pat. 114,304, 25.2.18. (Appl. 3336/18.) Int. Conv., 22.3.17.

In the manufacture of celluloid or films having a basis of cellulose acetate, the proportion of softening agents incorporated with the cellulose acetate is varied according to the relative viscosity of the latter. For example, with a cellulose acetate having a relative viscosity of 8–12, triacetin equivalent to 10–15% of the weight of the cellulose acetate may be incorporated, whereas with an acetate having a viscosity of 35–45 on the same scale, the proportion of triacetin may be increased to 40–50%. —J. F. B.

Cellulosic material; Method of treating threads of —. C. E. Vanderkleed, Collingswood, N.J., and J. E. Brewer, Norristown, Pa., Assignors to W. M. Field, Haverford, Pa., H. J. Verner, Bryn Mawr, Pa., and F. Heidlberg, Jersey City, N.J. U.S. Pat. 1,269,340, 11.6.18. Appl., 5.8.16.

A LAYER of cellulose is deposited upon threads of cellulosic material, or upon fabrics made of such threads, by passing them through a cuprammonium solution of cellulose and then subjecting them to the action of acid. Copper and ammonium salts are removed by washing.—F. C. T.

Paper; Etchable coated — for the production of backings or surfaces for printing illustrations. J. Miln, Toronto, Canada. Eng. Pat. 119,368, 4.1.18. (Appl. 250/18.)

PAPER is coated with a composition prepared with 290 lb. of "blanc fixe," 580 lb. of china clay, and 65 galls. of water mixed with a solution containing 125 lb. of gelatin, 2 lb. of glycerin, and 12 oz. of aluminium acetate in 25 galls. of water. The coated paper is printed with a medium capable of resisting the etching liquid, and then treated for a short time with a dilute solution of bleaching powder. The acidity of the aluminium acetate causes the formation of hypochlorous acid which destroys the binding qualities of the gelatin in the exposed portions of the coating, so that the materials of the coating can be washed away, leaving the printed device in relief.—J. F. B.

Paper making machines [; Suction-boxes of —]. W. A. Aitken, Gravesend. Eng. Pat. 119,594, 14.1.18. (Appl. 832/18.)

In a Fourdrinier paper machine the suction-boxes are mounted on a carrier-frame, pivoted at the centre on one side of the machine and oscillated in a horizontal plane over a limited path on the

other side of the machine. The oscillating motion is imparted by a slow-speed reciprocating gear operating on the carrier-plate remote from the pivoted plate. The movement of this plate is regulated by a roller-pin situated in a curved slot having a radius centred at the pivot. The swinging oscillation of all the suction-boxes simultaneously enables the wire to guide freely and keep to its running centre.—J. F. B.

Paper; Method and means for finishing — [to produce a cloth finish]. H. J. Guild, Assignor to Eastern Manufacturing Co., Bangor, Me. U.S. Pat. 1,277,714, 3.9.18. Appl., 9.12.16.

BELTS of suitable textile material are fed between two rollers, the paper under treatment lying between the belts. One of the rollers is of a hard material, and the other is of a material sufficiently yielding to bring about a slight relative motion between the paper and the belts while under the pressure of the rollers, but at the same time has sufficient compressive rigidity to ensure that each side of the paper receives an impression of the textile belt with which it is in contact.—L. A. C.

Paper; Process and means for producing all-wood —. A. H. Lefebvre, Watertown, N.Y. U.S. Pat. 1,277,737, 3.9.18. Appl., 16.2.17.

WOOD is ground to produce a mixture of fine fibrous material and partially reduced material, the pulp from the grinder is passed through a scrubbing tank and then through a hydrostatic gravity separator, in which the foreign matters are separated; the cleaned material is then screened and the portions which are rejected by the screens are treated in a refiner to produce a relatively coarse fibrous pulp which is mixed with the pulp coming from the original grinder, so that it again passes through the grading system.—J. F. B.

Paper pulp; Method and apparatus for bleaching —. J. E. Heiskanen, Canton, N.C. U.S. Pat. 1,277,926, 3.9.18. Appl., 7.2.18.

THE pulp is treated in a series of circulating units, each consisting of a pair of vertical tanks, the bottoms of which taper to a connecting passage in which a propeller is situated. Adjustable means are provided whereby a portion of the pulp circulating in each unit is allowed continuously to flow over into the next unit of the series, whilst the remainder is returned to the tank from which it was propelled, the amount of pulp continuously passing over from each unit to the next being equal to the amount continuously fed into the apparatus. —J. F. B.

Paper-pulp; Beating or grinding of —. E. Partington, Westwood Park. U.S. Pat. 1,277,637, 3.9.18. Appl., 23.3.18.

SEE Eng. Pat. 110,482 of 1917; this J., 1917, 1232.

Fireproofing composition. U.S. Pat. 1,276,742. See I.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Silk weighting with zirconium sulphate. E. Ristenpart. Färber-Zeit., 1918, 29, 26.

EXPERIMENTS show that the weighting of silk by zirconium sulphate cannot replace the weighting by tin salts.—L. L. L.

Vat dyestuffs; Explanation of the printing of coloured reserves on some —. R. Haller. *Färber-Zeit.*, 1918, 29, 1-3.

In the author's method of printing coloured reserves with vat dyestuffs (this J., 1918, 462 A), Pomeranz (*loc. cit.*) considers that the Indanthrene vat does not penetrate the printed vat colour, because the caustic soda necessary to fix the Indanthrene dyestuff from the vat is not available, having reacted with the iron and manganese reserve salts, with the formation of hydroxides of these metals. The author holds that the hydroxides of zinc and manganese are in a colloidal condition in the printing thickener, and form a membrane which prevents the penetration of the Indanthrene, which is in a colloidal form in the dye-vat. The caustic soda of the Indanthrene bath will, however, penetrate the colloidal matter of the printed colour, and, along with the reducing agent in the printed reserve, will be able to reduce and fix the printed colour on the cloth. The author also considers that the process used at the Fehmayer works, in which reserve effects are produced by printing with manganese chloride, bichromate, gelatin, etc., for blue and red effects, also supports his view. Manganese dioxide produced on the fibre, in presence and in absence of glue, shows entirely different forms, especially when the fibre is treated with cuprammonium solution. In the first case there is a continuous membrane in which the manganese dioxide particles are perfectly uniform throughout the fibre. In the second case the fibre swells, passes into solution, and leaves the manganese dioxide in comparatively coarse form. The author considers that all varieties of thickening agents must act as a filter to prevent the colloidal vat dyestuff from passing through to the fibre.

—L. L. L.

Vat dyestuffs; Printed reserves with —. II. Pomeranz. *Färber-Zeit.*, 1918, 5, 51-54. (See also this J., 1918, 462 A.)

The removal or stripping of Indigo from a fabric by reduction and solution in caustic alkali is not successful because of the re-oxidation of Indigo-white. This is prevented by converting the Indigo-white, with the aid of zinc oxide and a quaternary ammonium base, Leukotrop W (B.A.S.F.), into a compound stable in air, which is soluble in alkali and can thus be removed from the fibre. This process has made the reduction method of stripping a commercial success. It also renders possible the printing of bright Indanthrene effects upon an Indigo ground. Oxidation reserves either convert the Indigo-white into insoluble lakes, and therefore prevent its fixation on the fibre, or prevent the vatted dyestuff from fixation on fibre without the intermediate oxidation. Copper salts, both soluble and insoluble, have been found to be good oxidising reserves. The production of red reserves with Paranitriline Red requires absence of copper compounds, and such reserves have been obtained by the use of sparingly soluble salts of *m*-nitrobenzenesulphonic acid; these salts, however, cannot be used with alkaline prints on account of the formation of soluble alkali salts. For Indanthrene vats, aluminium, ammonium, and manganese chlorides are used along with many filling agents, such as clay, lead sulphate, etc. The remarkable observation that the addition of reducing agents to a vat dyestuff, along with the above-mentioned salts, gives a vat reserve, renders possible the production of vat grounds and vat coloured effects. The author discusses Haller's explanation of the production of coloured reserves by printed vat dyes (see preceding abstract), and points out the possibility of the unreduced easily vatted dyestuff acting as an oxidising agent on the more difficultly vatted dyestuff, and so itself acting as a reserve.—L. L. L.

Waterproofing [fabrics]. E. Jentzsch. *Färber-Zeit.*, 1918, 29, 3.

For the waterproofing of lightly woven fabrics, so that water will not drop through, but may very slowly penetrate, the author finds that basic acetate or formate of aluminium is the most suitable, prior to wax-proofing.—L. L. L.

Pyrrole Blacks. Angeli. See IV.

PATENTS.

Yarns or fabrics; Machines for boiling, bleaching, dyeing, sizing, or similarly treating —. J. Bright and Bros., Ltd., and J. Evans, Rochdale. Eng. Pat. 119,173, 22.1.18. (Appl. 1225/18.)

In a continuous line of machines for treating yarns or fabrics in the rope state, comprising a series of boxes each with a pair of gripping or drawing-through rollers, guide rollers are provided immediately before and after the squeeze rollers, the guide rollers being mounted on yielding bearings controlled by springs, which take up any irregularities in the tensions of the yarns and prevent undue stretching and breakage.—J. F. B.

Textile fabrics; Printing of —. The Calico Printers' Association, Ltd., and F. Ashton, Manchester. Eng. Pat. 119,298, 5.10.17. (Appl. 14,391/17.)

The fabric is first treated with a chrome mordant, then padded with one of the customary "naphthol prepares," and dried. It is next printed with a suitable diazo compound, e.g. a diazo derivative of nitroaniline, α -naphthylamine, etc., and a discharge mixture capable of discharging the chrome mordant is overprinted wholly or partially on the portions of the fabric which had previously received the azo colour. A suitable discharge may contain citric or tartaric acid or a salt of these acids. The fabric is subsequently dyed with any suitable mordant dyestuff.—J. F. B.

Stains; Removal of — from cloth. Th. Goldschmidt A.-G., Essen. Ger. Pat. 306,707, 19.4.17.

Glycol or a mixture of glycol and water is used to remove stains (coffee, chocolate, wine, etc.) from cloth, not removable by petroleum spirit.—L. A. C.

Fabric pieces; Processes and plant for treatment [weighting] of —. Wegmann & Co., Baden. Switzerland. Eng. Pat. 111,466, 3.10.17. (Appl. 14,290/17.) Int. Conv., 18.11.16.

Laundry starch. U.S. Pat. 1,276,722. See XVII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Concentration of — by the Kroll-Strzoda tube system. W. Strzoda. Z. angew. Chem., 1918, 31, 185-187.

The preliminary concentration of chamber acid from 50° B. to 60° B. usually takes place in the Glover towers or in open lead pans. Closed vessels are

used for further concentration to avoid loss of acid in the distillate, which reaches a strength of 60° B. as the concentration approaches 97–98%. Few substances are sufficiently resistant to acid to be used for the construction of the necessary plant. At one time platinum and glass were used. The Kessler-Düron concentrator is constructed of vulcanite, and the concentration is effected by means of hot gases from coke or coal furnaces working on the counter current principle. In this apparatus it is not economical to concentrate the acid above 93–94%. Later iron boilers have been brought into use in the Hartmann-Benker film concentrator and other apparatus. In the Krell-Strzoda process of concentration (Eng. Pat. 26,732 of 1913; this J., 1914, 643), the concentration tubes and certain other parts are made of an acid-resisting iron enclosed in a shell of cast iron, the intermediate space being filled with an acid-proof cement, which seals any cracks which may appear in the brittle acid-resisting iron during use. The concentrating tubes are arranged parallel on the slightly inclined bed of a furnace. They are connected with each other and with the distillate receiver in such a manner that the acid passes from the first tube to the second, and so on through the series to the acid cooler and receiver. The distillate is taken from the top of a crescent-shaped bend in the connection between each two tubes to a cooler and receiver. Advantages claimed for this process are that the working conditions are easy to control, a comparatively short time is required for the construction of the plant, for subsequent repairs or renewals and cleaning, and that a colourless, clear, pure quality of acid is produced. In a small Krell-Strzoda plant of up to 6 tubes, the production is somewhat less than 0.9 ton of 97–98% acid per tube per 24 hours, and 0.9–1.0 ton with more than 6 tubes. The coal consumption is about 4 cwt. per ton of 97–98% acid. Instead of condensing the distillate from the Krell-Strzoda plant in water-cooled lead pipes, H. Petersen passes the hot vapour up a small tower, in which it is dissolved by a descending stream of 50% chamber acid, yielding acid of 85–90%, which is passed again through the concentrating apparatus. The process is now in operation in several works. It is essential that the tubes be kept clean and free from slime and incrustation, as otherwise they are burned and soon require renewal.—S. S. A.

Potassium salts: Deposits of — at Dallol (Erythraea). M. Giua. Atti R. Accad. Lincei, 1918, 27, I., 331–335.

The analytical results are given of a number of samples from the salt deposits of Dallol in S. Danacalia (Erythraea). At many points these deposits consist largely of potassium chloride (up to 98.6%), whilst at others sodium chloride predominates. In all cases the proportions of magnesium chloride are low, and only traces of bromides are present in a few instances. The potassium minerals occur at the surface, and are localised at certain points of the salt area. The thermal springs of Dallol have a temperature of about 80°–90° C., and consist of saturated solutions of magnesium chloride containing traces of sodium chloride and appreciable proportions of magnesium bromide.—T. H. P.

Nitrites and nitrates in mixtures: Methods for the determination of —. A. Oelsner. Z. angew. Chem., 1918, 31, 170–172, 178–179.

Various methods are discussed for the determination of nitrites and nitrates in presence of each other, for instance in culture media for nitrifying and denitrifying bacteria. The diphenylamine reaction may be employed for the estimation of nitrates colorimetrically or, at a certain dilution, for that of nitrites. The nitrate reaction is stated to be

more intense with diphenylbenzidine, and the nitrites may be separately determined by permanganate. Various gasometric methods have been based on the decomposition of the nitrite with formation of nitrogen or nitric oxide. Ferrous chloride in acetic acid solution decomposes the nitrite only; afterwards if hydrochloric acid be added the nitrate is also decomposed. The decomposition of the nitrite may alternatively be effected by boiling with ferrous sulphate alone, without acid, or nitric oxide may be liberated by the action of potassium iodide and dilute hydrochloric acid. According to Winogradsky's method the nitrite is converted into nitrate by titration with permanganate, and the total nitrate then determined as nitric oxide by Schloesing's method. The author has worked out another method based on the oxidation of the nitrite by permanganate and the determination of the total nitrate as ammonia after reduction by zinc and iron in alkaline solution. The titration with permanganate is carried out in acid solution. On account of the volatility of nitrous acid, the nitrite solution is added from a burette to the permanganate, previously acidified with sulphuric acid and heated to 40° C. Towards the end, the nitrite solution must be added quite slowly because the discharge of the pink colour requires some time; after the titration it is advisable to add permanganate until a faint permanent pink is restored. For the nitrate determination it is necessary to take a quantity equivalent to between 10 and 30 mgrms. of nitrogen; with less than 10 mgrms. the results are too high, and with more than 30 mgrms. they are too low. If it is necessary to employ a larger quantity of the solution than for the nitrite titration, a corresponding quantity of acidified permanganate must be added to oxidise the nitrite. With pure mixtures of nitrite and nitrate the method is accurate to within 1–2 mgrms. of total nitrogen per 100 c.c., and affords a good measure of the course of the nitrifying process, provided ferrous salts are excluded from the culture medium. The media generally contain citric acid, but the action of the latter on permanganate is so slow that the nitrite titration is not appreciably affected on this account, although a small constant error may be introduced by the action of certain other reducing substances. The influence of ammonium compounds on the total nitrogen determination is avoided by boiling the liquid with alkali before reduction of the nitrate. A feasible method for the determination of nitrites and nitrates in the presence of much organic matter, by precipitation with nitron, has been investigated by Franzen and Löhmann (this J., 1909, 546). Nitrites may be eliminated without conversion into nitrates by precipitation with 2,4-diamino-6-hydroxypyrimidine sulphate, or may be converted into methyl nitrite with standard hydrochloric acid and methyl alcohol and the loss of acidity determined by titration. The residual nitrate may then be reduced to ammonia.—J. F. B.

Sulphates: Volumetric determination of —. Vansteenberghe and Bauzil. Ann. Chim. Analyt., 1918, 23, 210–214.

The solution is heated at 60°–70° C. with an excess of sodium carbonate, filtered, the filtrate acidified with hydrochloric acid, and boiled for 1 min. with a measured excess of 1.22% barium chloride solution. The barium sulphate is collected on a filter, washed, and the excess of barium in the filtrate is precipitated as carbonate by the addition of sodium carbonate. The barium carbonate is collected, washed, and titrated with N/10 hydrochloric acid, using methyl orange as indicator. The method may be used for the determination of sulphates in urine, serum, blood, etc., after these have been suitably clarified.—W. P. S.

Gas-purification masses; Examination of spent —
A. Müller. Chem.-Zeit., 1918, 42, 457.

THE suggested conventional method of determining sulphur and cyanogen (Prussian blue) in the spent purification sludge from gas-works (this J., 1918, 165 A) is open to criticism. In the determination of the sulphur errors may easily result during the measuring of the carbon bisulphide solution, whilst there is no proof that extraction of the sulphur is complete. In the author's experience Drehschmidt's method of extraction (J. Gasbel., 1892, 269) is much more trustworthy and rapid. The extraction crucible is a cylindrical porcelain vessel with a perforated bottom, upon which is placed a layer of glass-wool and a compact layer of asbestos. From 15 to 20 grms. of the sample is dried in this crucible at about 80° C. until constant in weight, the crucible then introduced into the extraction apparatus, and the sulphur extracted with about 70 c.c. of carbon bisulphide. For the determination of Prussian blue Feld's method (J. Gasbel., 1904, 545) is more rapid and accurate than Knublauch's method (this J., 1889, 732) based on the interaction of copper sulphate and potassium ferrocyanide:—Two grms. of the spent material is triturated in a mortar with 1 c.c. of ferrous sulphate solution (278 grms. per litre) and 5 c.c. of sodium hydroxide solution (320 grms. per litre), and, after 5 mins., 30 c.c. of magnesium chloride solution (610 grms. per litre) is slowly stirred in, and the whole washed into a distillation flask with sufficient hot water to make up about 200 c.c. After about 5 mins. 100 c.c. of boiling mercuric chloride solution (27.1 grms. per litre) is added to the boiling liquid, and the boiling continued for about 10 mins. The flask is then connected with the distillation apparatus, the receiver of which is charged with 20 c.c. of sodium hydroxide solution (80 grms. per litre), and after the introduction of 30 c.c. of dilute sulphuric acid (392 grms. per litre), the liquid is distilled for about 20 to 30 mins. The distillate is made up to 250 c.c., a trace of lead carbonate being added to remove any turbidity due to sulphur, and 100 c.c. is treated with 5 c.c. of potassium iodide solution (41.5 grms. per litre) and titrated with N/10 silver nitrate solution, 1 c.c. of which is equivalent to 0.009556 gm. of Prussian blue, $\text{Fe}_7(\text{CN})_{12}$.—C. A. M.

Cyanogen products [; Reactions of —]. V. Macri. Boll. Chim. Farm., 1918, 57, 261–265.

CRUDE carbonylferrocyanide from the wash waters of Laming's gas-purifying mixture was purified, and the pure product, and also alkali cyanide, thiocyanate, and ferrocyanide, were subjected to the action of a number of reagents; the results are tabulated. The carbonylferrocyanide is a highly stable compound.—T. H. P.

Radium emanation; Apparatus for the separation of — and its determination electroscopically. J. E. Underwood and H. Schlundt. Amer. Electrochem. Soc., Sep.—Oct., 1918. [Advance copy.] 7 pages.

THE apparatus (see fig.) consists of a flask, A (150 c.c.), provided with a rubber stopper, a sealed inlet tube, C, and an outlet tube which is connected with a U-tube, B, containing concentrated sulphuric acid. B is connected, through a bent tube, Y, and a trap, E (containing glass wool impregnated with sulphuric acid, and an upper layer of cotton), with a gas burette, F (200–300 c.c.), containing mercury. In conducting a determination of radium in monazite sand or concentrate, the mercury is run to the top of the burette and the stopcock closed. To the flask, containing a weighed quantity (10 grms.) of the sample, about 75 c.c. of concen-

trated sulphuric acid is added and the flask attached quickly to the apparatus. The burette is then connected with the flask, the levelling vessel lowered, and the sample boiled with the acid under somewhat reduced pressure. When decomposition is complete the flame is removed and the tip of the inlet tube, C, broken, thus admitting air by which the emanation remaining in the flask and train is carried into the burette. After standing for about 10 mins. to allow the thorium emanation to decay, the gas is transferred from the burette to an

ionisation chamber previously exhausted, the gas left in the connecting tubes of the electroscopie being swept into the chamber by fresh portions of air drawn into the burette through the inlet tube, C. The ionisation current in the electroscopie is measured after a lapse of three hours when, the calibration constant of the instrument being known, the quantity of emanation is readily deduced. To the value so obtained is added that fraction of the emanation which is continuously emitted at ordinary temperatures, and for which a determination on a separate sample is necessary. —W. E. F. P.

The compound $\text{H}_2\text{B}_4\text{O}_7$ and its salts [borites]. R. C. Ray. Chem. Soc. Trans., 1918, 113, 803–808.

THE product obtained by heating a mixture of magnesium powder and anhydrous boron trioxide (passing a 120-mesh sieve) to a bright red heat in a current of hydrogen contains magnesium borite, MgB_4O_7 . This has not been isolated, but its aqueous solution, when treated with the equivalent amount of potassium hydroxide and concentrated after filtration, yields the potassium salt, $\text{K}_2\text{B}_4\text{O}_7$, crystals stable in the absence of moisture. Determinations of the molecular weight in water by the cryoscopic method indicate that the formula is $\text{K}_2\text{B}_4\text{O}_7$, not KB_2O_3 .—C. S.

Wood charcoal in jacketed vessels for the storage of liquid oxygen; Spontaneous explosion of —. L. Wöhler. Ver. dent. Chem., Sep., 1918. Z. angew. Chem., 1918, 31, 192.

LIQUID oxygen is stored in double-walled metal containers, the vacuum jacket being packed with specially prepared wood charcoal. One c.c. of good "vacuum charcoal" will absorb, at the temperature of liquid air, 1 litre of oxygen and 1 litre of nitrogen, which is about double the absorption capacity of ordinary wood charcoal. The charcoal

packing thus protects the evacuated space against gradual small leakages and prolongs the efficiency of the container. Cases have occurred where in consequence of an injury to the inner wall, liquid oxygen has penetrated to the charcoal, causing a violent explosion. Not every kind of "vacuum charcoal" is explosive, and ordinary wood charcoal is quite indifferent. The activity of the explosive charcoal has been traced to the presence of iron in the form of ferric oxide, which acts as an oxidation catalyst. The heat generated by the absorption of oxygen by the "vacuum charcoal" of high absorption capacity serves as an initial exciter for the catalytic oxidation and the combination of high absorption capacity with the presence of ferric oxide is a necessary condition, since ordinary charcoal, even with the addition of ferric oxide, is non-explosive. "Vacuum charcoal" becomes explosive in presence of 2–3% of iron in the form of ferric oxide deposited *in situ*, not merely mixed as a powder. The percentage of iron in the sample is, however, no guide to its dangerous or safe character, since if the iron be concentrated in certain portions of the sample, the explosion may start in these portions and extend to the remainder of the mass. Explosions have been recorded with charcoal having an average content of 0.6% of iron.

PATENTS.

Phosphoric acid solutions; Process of treating — F. K. Cameron, Washington, D.C. U.S. Pat. 1,276,870, 27.8.18. Appl., 11.11.16.

AN aqueous solution containing not less than 12% of phosphoric acid is treated with sufficient excess of gaseous ammonia under pressure to precipitate the whole of the phosphoric acid as tri-ammonium phosphate. A portion of the ammonia is afterwards recovered by converting the tri-ammonium phosphates into an ammonium phosphate or mixture of phosphate containing a smaller proportion of ammonia.—L. A. C.

Potash or potassium salts; Extraction of — from potash-bearing materials. E. A. Ashcroft, London. Eng. Pat. 119,492, 28.8.17. (Appl. 12,363/17.)

To extract potash from potash-bearing materials, such as felspar, muscovite, micas, and the like, the material, either alone or mixed with a reducing material (*e.g.*, carbon or a sulphide) is suspended in a fused medium of sodium chloride or potassium chloride, or both, and treated with chlorine gas at a suitable temperature. A chlorine carrier or catalyst (*e.g.*, an iron salt) may be added with advantage, and the operation is preferably conducted in a converter. The potassium is converted into chloride, which is extracted with water.
—J. H. P.

Hydrogen peroxide; Stable — and method of making the same. A. Schaidhauf, Frankfurt, Germany, Assignor to Roessler and Hassbacher Chemical Co., New York. U.S. Pat. 1,275,765, 13.8.18. Appl., 2.8.12.

A NON-ACID solution of hydrogen peroxide is treated with an insoluble aluminium compound, giving as a stable end product a solution of hydrogen peroxide with "sensible proportions" of the insoluble aluminium compound.—C. A. K.

Manganese compounds [dioxide]; Making — C. Ellis, Montclair, N.J., Assignor to National Carbon Co., Inc., New York. U.S. Pat. 1,276,739, 27.8.18. Appl., 27.10.17.

RAW material containing basic manganese compounds is heated with acid sodium sulphate to form manganese sulphate which is then converted into manganese dioxide.—W. E. F. P.

Tungsten trioxide; Method of producing finely divided — C. A. Pfanstiehl, Waukegan, Assignor to Pfanstiehl Co., Inc., Chicago, Ill. U.S. Pat. 1,277,475, 3.9.18. Appl., 19.11.14.

AN aqueous solution of ammonium paratungstate is treated with nitric acid in a very finely divided state to precipitate tungsten trioxide as a fine powder.—J. H. P.

Aluminium oxide; Process of manufacturing — from aluminium silicate or a substance containing aluminium silicate and obtaining sodium carbonate as a by-product. Y. Takeshima, Tokyo, Japan. U.S. Pat. 1,277,503, 3.9.18. Appl., 23.10.17.

A MIXTURE of aluminium silicate, calcium carbonate, sodium sulphate, and carbon in the molecular proportions corresponding to: $x\text{Al}_2\text{O}_3$, $y\text{SiO}_2 + 2x\text{Na}_2\text{SO}_4 + (2x + 2y)\text{CaCO}_3 + 4x\text{C}$, is extracted with water after roasting. Carbon dioxide is passed into the solution obtained to precipitate aluminium hydroxide and obtain sodium carbonate as a by-product.—J. H. P.

Lime; Process of slaking — W. E. Carson, Riverton, Va. U.S. Pat. 1,277,855, 3.9.18. Appl., 11.10.17.

To obtain a dry hydrated lime, quicklime is mixed with a quantity of water "sufficient for hydration and evaporation," the chemical action allowed to proceed for a time until a predetermined temperature has been reached, and the mixture then suddenly chilled to a lower temperature at which the slaking is completed. A catalyst may be added.
—J. H. P.

Hydrogen; Manufacture of — C. T. Thorssell and H. L. R. Lundén, Gothenburg, Sweden. Eng. Pat. 119,591, 9.1.18. (Appl. 549/18.)

IRON sponge in the form of thin leaves or balls is impregnated with a strong solution of sodium or potassium carbonate or hydroxide, and dried at a moderate temperature. Alternatively the sponge may be pulverised, mixed with 10% of its weight of sodium carbonate, and water, and the mixture moulded and dried. When used in the manufacture of hydrogen by alternate oxidation by steam and reduction by reducing gas, the activity of this material does not deteriorate.—W. F. F.

Wool-scouring liquors. U.S. Pat. 1,277,784. See V.

Electrolytic cells. Eng. Pat. 118,355. See XI.

VIII.—GLASS; CERAMICS.

Glass furnaces; Formation of certain rock-forming minerals in and about — G. V. Wilson. J. Soc. Glass Tech., 1918, 2, 177–216.

AN examination of material from a glass furnace at Kinghorn, Fife, which had burst owing to the solvent action of the molten glass on the floor of the tank, and of other specimens showed that under certain conditions wollastonite, augite, tridymite,

and quartz can all crystallise out from the same melt, the wollastonite crystallising out before the tridymite, and the latter occurring only where the mass cools slowly. Felspar (oligoclase), magnetite, and biotite (black mica) are formed by the corrosive action of hot molten glass on aluminous materials, such as bricks and pots. Wollastonite, melilite, $3\text{CaO} \cdot 2\text{SiO}_2$, and augite are also produced in fragments of limestone enclosed in molten glass, and generally as a result of the contact alteration of limestones by igneous materials. Augite is formed first and removes the bulk of the magnesia, some alumina, and some iron from the melt; the remaining alumina then combines with lime, silica, and a little soda, magnesia, and iron to form melilite, and the excess of lime and silica separate partly as wollastonite and partly as $3\text{CaO} \cdot 2\text{SiO}_2$. Sillimanite and corundum are formed by changes which occur in the refractory materials (clays) used, these changes being influenced by the presence of a little glass or other fluxes. The corundum appears to be formed from a part of the sillimanite which has been dissolved or re-dissolved in the mass. The effect of the gradual absorption of soda by bricks or glass pots is shown in a diagram. As the brick is gradually destroyed, the sillimanite first formed disappears, its silica and part of its alumina going to form felspar and feldspathoid molecules, whilst the remainder of its alumina separates as corundum. The absence of pseudowollastonite (αCaSiO_3) shows that the temperature of the molten glass at the commencement of crystallisation was not above 1190°C . (inversion temperature of pseudowollastonite to wollastonite). The absence of cristobalite indicates that the temperature was at no time as high as 1450°C . (inversion temperature of cristobalite to tridymite). The presence of quartz crystals in the amethyst glass in the lower part of the material suggests that the latter remained fluid below 870°C . (inversion temperature of tridymite to quartz). The absence of quartz in the main body of the glass shows that the latter had solidified at 870°C . or had become too viscous to allow of crystallisation. Molten glass has a rapid solvent action on the common bricks with which it comes in contact, forming oligoclase felspar with a little biotite and magnetite. A fragment of firebrick which had been for a long time enclosed in molten glass was full of sillimanite needles, except in the areas in contact with the glass. The action of molten glass on the refractory materials in the furnace results in the abundant formation of corundum on the inside of the crown of the furnace, and sillimanite in the sides and bottom. The sillimanite is normally only developed in the vitrified portions of the pot or brickwork. The junction between the glass and an aluminous pot or brickwork is almost a straight line, but the surface of a silicious refractory material is much corroded by the glass. Hence, the clays used for glass pots should be as aluminous as possible. The various minerals were separated as follows: Sillimanite was left after treating the material with dilute hydrofluoric acid. Corundum was left after boiling fragments of the material with fused sodium carbonate for several hours and treating the residue with strong hydrochloric acid. Wollastonite and tridymite were separated by gravitation in a mixture of bromoform and benzol of such density that the wollastonite sank and the tridymite floated. The properties by which the different minerals were identified are fully described, and their mode of formation as represented by Rankin and Wright's concentration-temperature diagram for the system lime-silica (this J., 1915, 139) and Shepherd and Rankin's corresponding diagram for the system silica-alumina (this J., 1909, 1124; 1911, 543) is discussed.—A. B. S.

Glass pots; Firing of —. M. W. Travers. J. Soc. Glass Tech., 1918, 2, 170—174.

IN gas-fired glass furnaces, the empty pot should be completely enclosed in the furnace (this J., 1918, 235 T) and heated to 1350°C . for three days or until the pot material is completely vitrified and has a thick and even layer of sillimanite. A vitrified pot is not corroded by glass, but a biscuit one is rapidly attacked when at a temperature of 1200°C . or above. Glazing is unnecessary with vitrified pots, but when filling them with glass batch, the temperature should not be allowed to fall unduly.

—A. B. S.

[Glass] pot failure. S. N. Jenkinson and P. Marson. J. Soc. Glass Tech., 1918, 2, 175—176.

Pots fail by the bottom cracking when they have not been heated sufficiently before being filled. Distortion occurs when the pots are supported on bricks. In a down-draught furnace the bottom of the pots will be heated more than in an up-draught one and this should lessen the cracking.—A. B. S.

Glassware; Resistant properties of some types of foreign chemical —. J. D. Cauwood and W. E. S. Turner. J. Soc. Glass Tech., 1918, 2, 219—235.

WHEN examined by the method described in a previous paper (this J., 1917, 873), glasses containing a moderate proportion of boric and zinc oxides are the most resistant, those in which the zinc is replaced by aluminium being less advantageous. A proportion of boric oxide in excess of 12 mols. per 100 mols. of silica does not increase the stability of the glass. Boric oxide lessens the resistance of glass to alkali and hydrochloric acid. Resistance to acids is increased by raising the silica, but not the boric oxide content of the glass, the resistance to alkali being simultaneously reduced. Resistance to sodium carbonate is greatest in glasses containing alumina. Alkali-lime glasses are not very resistant to water; they behave well with strong caustic alkali, moderately so with dilute caustic alkali, and are attacked strongly by sodium carbonate. They are the best glasses available for resisting acid and are recommended for analytical operations involving the use of acid solutions. Lime glasses are not resistant to water and sodium carbonate. Alumina is a valuable all-round constituent, but may increase the difficulty of melting and working the glass. For chemical purposes, different glasses should be selected according to the reagents employed. Six glasses remained in the "Good" class in each of the six tests applied (boiling water, autoclave at 183°C ., 2N NaOH, N/10 NaOH, 2N Na_2CO_3 , boiling HCl); of these three were British, one American, and two German.—A. B. S.

Chemical glassware; Effect of the continued action on — of water, acid, and alkali. J. D. Cauwood and W. E. S. Turner. J. Soc. Glass Tech., 1918, 2, 235—239.

FLASKS selected as representative of the three types of glass made for chemical ware were repeatedly subjected to the action of various fluids. The surface of soda-lime chemical glasses increases in resistance on continued treatment with water or hydrochloric acid. The resistance of borosilicate glasses is slightly increased by repeated treatment with water, but not with hydrochloric acid. Not any of the glasses used for chemical ware are improved by the continued action of either caustic soda or alkali carbonate. The irregularities in the results obtained appear to be due to lack of homogeneity of the glass itself. It is useless to compare the resistance of

different glasses by making only one or two tests when the actual extent of attack is small or the results are fairly close together.—A. B. S.

Cataphoresis [of kaolin, clay, etc.]; Study of — S. Kondo. *Kōgyō-Kwagaku-Zasshi* (J. Chem. Ind. Tokyo), 1918, 21, 385–401.

EXPERIMENTS on the cataphoresis of kaolins, ball clay, earthenware-body, and silicic acid gave the following results:—Particles of kaolin suspended in water show a velocity of migration practically proportional to the voltage of the current, the velocity in the case of Georgia kaolin at the potential difference of one volt per cm. and at 20° C. being 19.2×10 cm. per second. The velocity of migration of kaolin particles is inversely proportional to the viscosity of the medium, and in time shows a decrease. The velocity is increased by the addition of small quantities of sodium hydroxide to kaolin, but is retarded by increasing the amount beyond a certain limit, e.g. 0.05% in the case of Georgia kaolin. In presence of small amounts of sodium hydroxide, the deposits of kaolin and of earthenware-body particles on the anode were sufficiently compact for weighing. The amount deposited increases with the voltage and strength of the current. The friction between plastic clay briquettes and steel plate is reduced practically to zero in a few seconds by the action of a weak electric current. Cataphoresis of sodium silicate solution yields pure silicic acid. The passage of a direct current causes an accumulation of soluble salts in ball clay at one end of a briquette.—C. A. M.

Firebricks; Corrosive action of flue dust on — J. W. Mellor and W. Emery. *Ceram. Soc., Refractories Sect.*, Oct. 17, 1918. [Advance proof.]

THE corrosive action of flue dust on firebricks was investigated by injecting various dusts through a Grayshaw burner into a gas-heated furnace, the time of heating, the velocity of the flue dust, and the nature of the atmosphere being under control. The dust-charged flame impinged on the surface of the brick being tested. The "dusts" used were a boiler flue dust of slate brown colour, a boiler flue dust of a brown colour, deep red-coloured dust from the top of the retort bench of a gas works, dust from the slag chamber between a steel smelting furnace and a regenerator, dust from a blast-furnace Cowper stove, "bull dog," red hematite ore, tap cinder, lime from calcined marble, lime and common salt (1:1), salt, sodium sulphate, salt and potash spar (1:1), and sodium silicate and calcium silicate (1:1). The effects obtained under oxidising conditions were as follows:

Dust	Firebrick	Silica brick	Fine-grained silica brick
Boiler dust high in lime and ferric oxide	d.P.; m.C.	—	—
Ferruginous boiler dust	s.P.; s.C.	—	—
Ochreous dust from retort brick	k.P.; s.C.	d.P.; g.C.	—
Basic slag	d.P.; s.C.	d.P.; m.C.	—
Ferruginous dust high in lime	k.P.; m.C.	d.P.; m.C.	—
"Bull dog"	—	d.P.; s.C.	—
Hematite (reducing flame)	—	d.P.; s.C.	s.P.; s.C.
Tap cinder	d.P.; m.C.	d.P.; m.C.	d.P.; s.C.
Lime	s.P.; m.C.	s.P.; m.C.	—
Lime and salt	s.P.; m.C.	s.P.; m.C.	—
Salt	d.P.; s.C.	s.P.; m.C.	—
Sodium sulphate	s.P.; s.C.	s.P.; m.C.	—
Salt and felspar	s.P.; s.C.	s.P.; m.C.	—
Soda-lime glass	s.P.; s.C.	s.P.; m.C.	—

NOTE.—P=penetration; C=corrosion; s=slight; d=deep; k=complete; m=medium; g.C.=great corrosion or slagging.

The dust penetrates more readily into fireclay bricks than into silica bricks. The bond is usually attacked first and the coarser grains last. In fine-grained silica bricks, the depth of penetration is less than with coarser grained ones. Under oxidising conditions, iron oxide does not corrode silica bricks to any noteworthy extent, but under reducing conditions, ferrous silicate is formed and acts as a corrosive flux. "Bull dog" dust and iron oxide generally corrode fireclay bricks more than silica bricks. The alkaline vapour in some dusts influences the conversion of quartz into a form of silica with a lower sp. gr. When the surface of a brick has been covered with a glaze formed by the action of the dust, the subsequent rate of corrosion is greatly diminished unless the glaze is sufficiently fluid to drip away; the corrosion is then rapid. Attempts to increase the resistance of the brick by applying a blowpipe flame to the surface were unsuccessful. The depth of penetration of the dust cannot be used as the basis of a quantitative measure of the corrosion.—A. B. S.

Refractory materials; Standardisation of tests for — Parts I. and II. Report of Committee of Ceramic Soc., Refractories Sect., May 15 and Oct. 18, 1918. [Advance proof.]

1. *Analysis of fireclays, ganisters, quartzose rocks, and manufactured products.*—*Hygroscopic moisture* is determined by drying about 5 grms. of the finely ground sample at 110° C. to constant weight. *Loss on ignition* is determined by heating about 1 gm. of the dry sample in a platinum crucible, first over a small flame, then over a Meker or Teclu burner, and finally over a blowpipe or in a muffle for about 20 mins., cooling, and weighing. After re-heating over the blowpipe for about 5 mins. the cooled crucible is re-weighed. *Silica* is determined by fusing 1 gm. of the sample with 10–15 grms. of sodium carbonate and treating the product with water and hydrochloric acid. The liquid is evaporated to dryness and the residue heated in an air oven at 110° C., moistened with hydrochloric acid, 60–70 c.c. of hot water added, and, after filtering, the residue is washed with hot water until free from chlorides, and is set aside. The filtrate is evaporated to dryness, heated as before, again treated with acid and water, filtered, and the residue washed. The two filter papers and contents are ignited slowly, then over a blowpipe for 15 mins. with the lid off, then finally 5 mins. with the lid on. The residue is weighed as "uncorrected silica"; it is treated with water, sulphuric acid, and hydrofluoric acid, evaporated to dryness, ignited over a burner for 5 mins., and weighed. The loss in weight represents silica. *Alumina, iron, etc.*, are determined by adding solid ammonium chloride and ammonia to the filtrate from the silica, the latter being at 80°–90° C., and filtering off the precipitate immediately. The residue is washed, dissolved in hydrochloric acid, and the alumina, etc., is re-precipitated by adding an excess of ammonia. It is filtered off, and washed with a solution containing 5 c.c. of concentrated nitric acid and excess of ammonia in 1 litre. The combined filtrates are evaporated to about 100 c.c., ammonia is added, and the precipitate filtered off and washed with the ammonium nitrate solution. The three filter papers, with contents, are dried in the platinum crucible containing the "silica residue," ignited, cooled, and weighed. The precipitate is fused slowly with 5–6 grms. of fused potassium bisulphate or pyrosulphate, dissolved in dilute sulphuric acid, made up to 250 c.c., and retained for determining the iron and titanium. *Ferric oxide* is determined by the ordinary permanganate process, or preferably colorimetrically with potassium thiocyanate, and

standard iron solution containing 0.6302 gm. of ferric potassium alum and 5 c.c. of concentrated sulphuric acid per litre. When the permanganate process is used, the iron is reduced with sulphur dioxide, excess of which is removed by boiling, and finally by a current of carbon dioxide so as to avoid the reduction of titanium oxide. *Titanium oxide* is determined colorimetrically in the solution of the alumina, etc., precipitate by adding hydrogen peroxide and comparing the colour with that of 10 c.c. of a standard solution (containing 1 gm. of pure titanium oxide, 10 grms. of potassium pyrosulphate, and 10 c.c. of concentrated sulphuric acid per litre), diluted until the two tints are alike. The weights of iron and titanium oxides are deducted from the total weight of the alumina, etc., precipitate, and the difference is reported as alumina. *Lime* is precipitated as oxalate in the boiling filtrate from the alumina, etc., the solution is allowed to stand on a water-bath for two hours, filtered, the residue washed once, dissolved in nitric acid, and re-precipitated as before, the precipitate being washed well with hot water, dried, ignited, and weighed as lime. *Magnesia* is precipitated in the filtrate from the lime precipitate by sodium ammonium phosphate. The precipitate is filtered off, dissolved in nitric acid, and re-precipitated, collected in a Gooch crucible, washed with cold ammonia solution (1:8), ignited, and weighed as magnesium pyrophosphate. *Alkalis* are determined by the Lawrence-Smith method on 0.5 gm. of the finely powdered sample and are weighed as mixed chlorides. The potash is then precipitated by evaporating the chlorides with 30% perchloric acid and then with 10 c.c. of water. A mixture of 97 vols. of absolute alcohol, 3 vols. of water, and 0.25 vol. of perchloric acid is added, and the mixture filtered through a weighed Gooch crucible. The residue is washed with the alcohol mixture, dried at 120° C., and weighed as potassium perchlorate.

II. Analysis of dolomite and magnesite.—*Hygroscopic moisture* is determined as in I. *Loss on ignition* is determined as in I., but the ignition over a blast burner should be prolonged another 10 mins. *Alkalis* are determined as in I. *Silica* is determined by fusing 1 gm. of the sample as in I., care being taken to use an excess of acid in washing the silica. Two evaporations are seldom necessary. *Alumina, etc.* is determined after diluting the filtrate from the silica to about 300 c.c., as described in I., except that the re-precipitation of the alumina, etc., is seldom necessary. *Lime* is determined as in I. after diluting or evaporating the filtrate from the alumina, etc., to about 300 c.c. *Magnesia* is determined as in I. after concentrating the combined filtrates from the lime to about 300 c.c. Washing must be very thorough, and the material must be ignited throughout to at least 800° C. before weighing. *Phosphorus and sulphur* are determined by fusing 1 gm. of the sample with sodium carbonate, as for silica, but using a sulphur-free flame. The silica is removed as usual, the filtrate diluted to 500 c.c., and 250 c.c. taken for the phosphorus and sulphur respectively. Sulphur is precipitated as barium sulphate in the faintly acid solution, heated to 90° C., by barium chloride added slowly, with constant stirring, filtered after 3–4 hours, and the precipitate washed, ignited, and weighed. *Phosphorus* is determined by neutralising with ammonia, adding ammonium nitrate and nitric acid, heating to about 80° C., and precipitating with ammonium molybdate with constant stirring. After standing 3 or 4 hrs. the solution is filtered, the residue dissolved in ammonia, and re-precipitated with ammonium nitrate and ammonium molybdate, heated to 80° C. until gas bubbles begin to form, acidulated with hot 5% nitric acid with

constant stirring, and after standing 3 or 4 hrs. filtered through a Gooch crucible, the precipitate washed with the mixture previously employed, dried, ignited at 800° C., and weighed as $24\text{MoO}_3 \cdot \text{P}_2\text{O}_5$.

III. Identification of various forms of silica in silica bricks.—A suitable method of identification is by means of the refractive indices, which are respectively 1.549 for quartz, 1.477 for tridymite, and 1.484 for cristobalite. Becke's bright line method may be used, but preferably the material is immersed in a solution of mercury potassium iodide in water diluted until its refractive index for sodium light is 1.477; any tridymite present will then show ultramarine fringes, cristobalite, orange fringes, and quartz will be fringed with white light.

IV. Porosity, water absorption, and specific gravity tests.—A portion of the sample is cut into cubes of 2 in. side, dried at 110° C., weighed, soaked overnight in water under reduced pressure, and the sp. gr. determined by weighing in water. The surface is wiped and the piece is again weighed; the increase shows the amount of water absorbed.

V. Shrinkage of clays on drying and firing.—The clay is moulded to form a block measuring $4\frac{1}{2}$ in. \times $1\frac{1}{2}$ in. \times $\frac{1}{2}$ in. Two thin vertical lines are drawn on it about 9 cm. apart, their distance being accurately measured. The distance is again measured after drying the test-pieces at the ordinary temperature, then for 4 or 5 hrs. at 70°–80° C., and finally at 110° C. Each test-piece is also before and after drying weighed to ascertain the amount of water it contains. The test-pieces are fired in a muffle or sagger at the rate of 60° C. per hour to 900° C., and afterwards at 20° C. per hour, along with Seger cones to indicate the temperature. Test-pieces are drawn at the following cones and corresponding temperatures:—010a (900° C.), 08a (940°), 05a (1000°), 02a (1050°), 1a (1100°), 4a (1160°), and 6a (1200°) for lower temperatures, or at 010a (900° C.), 05a (1000°), 1a (1100°), 4a (1160°), 6a (1200°), 8 (1250°), 10 (1300°), 12 (1350°), 14 (1410°), and 16 (1460° C.) for higher temperatures, and the shrinkage, porosity, water absorption, and specific gravity determined, and the colour changes and hardness noted.

VI. Tensile strength of dried clays is measured in a machine similar to that used for cement. The test-pieces must be dried slowly and regularly and must break accurately in the middle. The average of five or six tests should be taken.

VII. After-contraction or after-expansion is determined as directed in the Gas Engineers' Specification (this J., 1911, 28, 804; 1912, 642; 1917, 701, 1273).

VIII. Normal refractoriness is determined on a test-piece of the material cut to the shape of a Seger cone (about $1\frac{1}{2}$ in. high), as described in the Gas Engineers' Specification (*loc. cit.*).

IX. Refractoriness under load is determined in a similar manner to normal refractoriness, but the test-piece is a rectangular block $3\frac{1}{2}$ in. long and 2 in. by 2 in. cross-section. The load is applied through a lever. The rate of heating should be such that Seger cone 16 (1460° C.) squats in 4 hrs.

X. The thermal expansion and the hot and cold sizes of firebricks are determined by Coppée's method (see this J., 1917, 1273).

XI. The crushing strength of cold materials is determined in a machine in which the load is applied with the utmost regularity. Hand-operated machines are not satisfactory. The opposite faces of the sample must be ground accurately parallel. At least five bricks should be tested.

XII. Grading.—Refractory materials should be tested for grading by means of standard sieves, preferably those established by the Institution of

Mining and Metallurgy (this J., 1907, 1240) in which the wire and aperture or mesh are of equal diameter. The material is made into a slip and washed through each sieve in turn, the residue on each sieve being afterwards dried and weighed. For the materials used in the manufacture of silica bricks, a set of three sieves (Nos. 5, 50, and 120) usually suffice. For finer materials, the use of a No. 120 and a No. 200 sieve, followed by elutriation to separate particles of less than 0.01 mm. diam. is desirable. Schoene's elutriator (omitting the manometer) is recommended, the water having a velocity of 0.18 mm. per sec. to remove particles of less than 0.01 mm. diameter. To obtain comparable results, distilled water should be used and the addition of acids, etc., to facilitate the disintegration of the material should be avoided, but a little ammonia may be used. To break up adventitious clots, the sample should be mechanically shaken with water for about 4 hours; some clays require a longer treatment. The material is then passed successively through a No. 120 and a No. 200 sieve and into the elutriator. In order to compare the fineness of two or more clays, the surface factor should be calculated (Trans. Ceram. Soc., 1910, 9, 94).

XIII. Corrosive action of flue dusts.—See preceding abstract.—A. B. S.

Silica bricks; Constitution of —. A. Scott. Trans. Ceram. Soc., 1917-18, 17, 459-474.

The chief properties required in rocks for the manufacture of silica bricks are a high percentage of silica, a small percentage of impurities—insufficient to reduce the refractoriness unduly, but large enough to accelerate the conversion of the quartz—and a structure which will give angular fragments when crushed. At least seven crystalline modifications of silica exist and one or more of them are present in a silica brick at some stage in its history. In the kiln, the bond (usually lime or clay) reacts with some silica dust to form silicates, and the remaining fine-grained quartz is converted first to cristobalite and afterwards to tridymite. The larger grains of quartz and ganister are attacked and dissolved by the fused silicates and are reprecipitated as cristobalite. When a fine-grained cement is present in the ganister used, conversion continues wherever the cement occurs. Some American bricks examined by the author contained only about 25% of unaltered quartz; the average in five British bricks made by different firms was 45%. The difference is due to the American bricks being burned at a higher temperature (cone 15 and above) and for a much longer time than those made in this country. Bricks which have been used in a furnace show a steady reduction in quartz and a corresponding increase in cristobalite and tridymite from the end which has been coldest to that which has been hottest. At a temperature of 1550° C., the matrix of a silica brick appears to consist of a very viscous, molten, saturated solution of silica in silicates of calcium, etc., and as the brick cools, the soluble silica crystallises out as well-developed skeletons of cristobalite, which may later be converted into tridymite. A piece of brick consisting wholly of tridymite was kept at 1550° C. for 2 weeks and was then quenched; the tridymite was unchanged, showing (in opposition to Fenner, this J., 1913, 22) that this is the most stable form of silica at high temperatures. When bricks in a furnace are attacked by dust, volatilised alkalis, etc., there is a greater formation of glass and a high proportion of cristobalite. Bricks in the roofs of steel furnaces, exposed mainly to iron oxides, exhibit several distinct layers; starting from the hot end of the bricks, these are: (i) A grey material show-

ing little trace of the original material, having apparently been molten, and consisting largely of tridymite with some cristobalite, and, in some cases, numerous minute particles of magnetite which fill the interstices between the tridymite crystals. In other instances, cristobalite predominates in the grey part of the bricks, together with some tridymite and numerous small skeletal crystals of fayalite. (ii) A black material partly structureless, but showing traces of the original structure and an appreciable amount of tridymite with more black magnetic iron oxide than in the grey portion. This magnetite occasionally reacts with the silica forming fayalite. (iii) A pale-coloured material resembling the unaltered brick, but containing a considerable proportion of cristobalite. (iv) A red material in which the matrix is partly converted into a very fine-grained aggregate, mainly cristobalite, and thin plates of hematite which produce the colour. (v) A narrow layer of unaltered material at the extreme end. The proportion of unaltered quartz falls steadily from the hot end to a point slightly beyond the centre of the brick, probably due to some local concentration of the fluxes. Bricks in the port of a steel furnace are penetrated for about 10 cm. by iron oxide. Sections of the lighter-coloured portions of the bricks resemble unused bricks, but show a greater conversion of the quartz in the matrix, the rock fragments being unaltered. Towards the hot end, the tridymite crystals are larger and the size of the rock fragments diminishes rapidly. Even at the hot end of such bricks some unaltered quartz exists with a matrix containing tridymite, iron oxide, and red crystals of fayalite. The amount of unaltered quartz probably depends on the size of grains of the original rock and on the port bricks being heated for a shorter time than those in the roof. The "slagging" or "dripping" of silica bricks in furnaces depends largely on the reduction of any iron oxide to the ferrous state, the ferrous oxide then reacting with the silica to form fayalite.

—A. B. S.

Silica products. A. Bigot. Ceram. Soc., Refractories Sect., Oct. 18, 1918. [Advance proof.]

SILICA products (especially the bricks used in steel furnaces) should not be softened, deformed, or show signs of fusion when heated to 1710° C. nor should they disintegrate on cooling. If a silica rock which expands considerably on heating to this temperature is to be used, it must be finely ground. Edge-runner mills should not be used for grinding the silica rock as they tend to produce rounded grains. Cylinder mills and other appliances used in the abrasive industry and yielding sharply angular grains are preferable. The bricks, etc., should be burned at about 1600° C., preferably in a tunnel kiln. Silica bricks taken from the arches of a Martin furnace at Creusot's works showed a zone of unaltered material and a second brown zone with white grains of unaltered material disseminated throughout its mass, but diminishing in number and size as the third zone was approached; this third zone was grey and devoid of grains of silica. On prolonged use the grey zone gradually increased and the brown zone diminished or invaded the zone of unaltered material. The brown material contained 78.45% SiO₂ and 13.10% Al₂O₃, as compared with 84.6% and 9.25% respectively in the grey material. The brown material also contained slightly larger proportions of lime, magnesia, manganese oxide, and alumina. The iron in the grey material was in the ferrous state (due to the penetration of the reducing gases in the furnace) and ferro-magnetite; in the brown material about half of it was attracted by a magnet. The brown

material melted abruptly and completely at 1710° C. The grey and unaltered materials passed through a pasty condition before melting at 1730° C. Under the microscope, the grey and brown materials showed a complete transformation of the silica into cristobalite and tridymite. The brown material contained much tridymite and free silica; the grey material presented a microgranular mass of cristobalite without action on polarised light. The crushing strength at ordinary temperatures of the brown and grey materials was greater than that of any commercial refractory material. The crushing strength at 1500° C. of the grey material was superior to that of all commercial refractory materials except carbon. The results obtained show that, contrary to general opinion, some silica bricks containing only 80% SiO_2 are as refractory as others containing 95% SiO_2 and have a much greater crushing strength than the latter. The proportion of lime and iron oxide in the grey material was 10–14%, whereas the permissible maximum in good silica bricks is usually considered to be 4%. These results are confirmed by previous investigations on enamelled silica bricks from the Temple of Darius (circa 500 B.C.) which contain about 11% of non-silicious matter and do not melt below 1730° C. On determining the crushing strength of refractory materials at various temperatures and plotting the results on a temperature-strength diagram, the author and V. Bodin found that clays, bauxites, silica products, and carborundum behave at first like a plastic substance and show a gradual reduction of strength with increasing temperature, followed by a rapid increase and a well-defined maximum strength at 1000° C., whilst chromite, magnesite, etc. show no such maximum. The only silicious material which behaved abnormally was the grey material previously mentioned; this did not soften on heating, but was disintegrated at 1500° C. The remarkably sharp maximum strength at 1990° C. shown by clays and similar materials may be associated with the gradual decrease in the expansion of materials which was observed by Edwards and Rigby (Trans. Ceram. Soc., 1917, 16, 271; Mellor, this J., 1917, 1273). If this is the case, magnesite and chromite should not show a decreasing expansion when heated. The temperature-strength graph furnishes new data which may be introduced into specifications for refractory materials.—A. B. S.

Silica and other refractory bricks made from non-plastic materials. G. W. Mottram. Ceram. Soc., Refractories Sect., Oct. 17, 1918. [Advance proof.]

REFRACTORY bricks should be made of particles of selected sizes, in such proportions as to give a product with the required characteristics. In the customary method of grinding ganister, calcined fireclay (grog), and other non-plastic materials there is usually a deficiency in the proportion of very fine material. Fireclay was finely ground with two or three times its weight of calcined Stourbridge fireclay and the product was mixed with ground calcined Stourbridge fireclay so as to produce a mixture containing 90% of calcined and 10% of raw clay. Bricks made from this mixture showed no contraction after repeated burning, and retained their sharp edges after a week's exposure in the port of an open-hearth steel furnace. The same principle may be applied to the grading of silica or other brickmaking material, grinding 15–30% of it with lime or other binder and then adding it to the remainder of the graded material. The durability of the product is two or three times as great as that made when the usual method of grinding is used.—A. B. S.

Magnesite as raw material [for refractories]. T. Crook. Ceram. Soc., Refractories Sect., Oct. 17, 1918. [Advance proof.]

The magnesite used for making refractory bricks should be dead-burned and crystalline, with not more than 5 or 6% of silica, alumina, and lime, and not more than 1% of iron oxide. Calcining must be effected at or above 1400° C., depending on the nature of the magnesite used. The sintered magnesite should be pulverised and graded before being made into bricks. The bricks should not shrink more than 15% when burned. The success of the Austrian magnesite bricks appears to be due to careful selection of material, efficient calcining, appropriate grading, and the use of sufficient pressure in making the bricks. The magnesites used for refractory purposes are spathic breunnerite (Styria), spathic magnesite (Quebec, Washington, and Norway), compact magnesite (Greece, California, Italy, India, and Australia), and hydromagnesite (Atlin, B.C.). The spathic varieties are coarsely crystalline and show definite cleavage; the compact or crypto-crystalline varieties show no cleavage. Spathic magnesite and breunnerite usually contain lime as an impurity; compact magnesite frequently includes an admixture of quartz, serpentine, and other forms of silica, but little lime and iron. Breunnerite—the variety of magnesite from which the Austrian magnesite bricks are made—contains a variable percentage of ferrous carbonate (cchalybite) in isomorphous admixture. It has an average sp. gr. of 3.15, whilst that of pure magnesite is only 3.02. On ignition the ferrous carbonate is converted into magnetite which gives the calcined material its characteristic black colour. The blackness and magnetic properties of the calcined breunnerite facilitate the separation of dolomite, calcite, and other impurities, which are not easily distinguished in the other varieties of calcined magnesite. Breunnerite also loses its carbon dioxide at a rather lower temperature than other forms of magnesite. The Austrian deposits are extensive, and the material is so easily quarried, readily purified, and cheaply burned by means of brown coal found in the locality that the sintered product can be placed on the market much more cheaply than other varieties of sintered magnesite. Breunnerite also occurs in Quebec, Mysore, and in uncommercial quantities in the United Kingdom. Spathic magnesite resembles marble and dolomite in texture, but has a slightly higher specific gravity. The adventitious dolomite, serpentine, and other impurities in it should be separated as far as possible at the quarry, as they are less easily recognised in the burned material. Spathic magnesite is characterised by a very low iron content (seldom above 2%). Compact or crypto-crystalline magnesite usually contains silica in the form of colloidal silica, quartz, or magnesium or other silicate. Before use, the adherent serpentine, calcite, etc. should be removed by hand dressing. Hydromagnesite is unsuitable for refractory purposes. In comparing the four varieties of magnesite, importance should be attached to the coarseness of the particles, as facilitating the separation of adventitious minerals, and to the effect of iron sulphide and other impurities. Iron oxide, when present, may increase the thermal conductivity of the material and so induce sintering at a slightly lower temperature. The end-product of calcination (periclase) is the same with each variety of magnesite, but it can be produced from breunnerite at a slightly less cost than from the other varieties. The deposits of breunnerite and spathic magnesite appear to be much larger than those of compact magnesite and are likely, therefore, to be preferred by those requiring magnesite as a refractory material. Analytical

and statistical figures and details of the distribution and geological characters of the various forms of magnesite are given.—A. B. S.

Magnesites and magnesite bricks. W. Donald. Trans. Ceram. Soc., 1917-18, 17, 486—561.

AUSTRIAN magnesite (from the Veitsch and neighbouring valleys), a massive crystalline spar of a yellowish-white to light yellow colour with lamellar grain and intrusions of chalybite (FeCO_3), chlorite schists, serpentine, and various other silicates, is much less pure than Greek magnesite, but is washed and carefully hand-picked before and after calcination. The composition of the dead-burned product is very uniform averaging 85% MgO , 8% Fe_2O_3 , and 3% SiO_2 . The sp. gr. of the raw material is 2.63 to 3.1, that of the caustic magnesite 3.2, and of the dead-burned product 3.545. Grecian magnesite (chiefly from Euboea) when calcined averages over 90% MgO , 3% CaO , 0.7 Fe_2O_3 , and 4% SiO_2 . The chief impurities are dolomite, quartz, and material from the overburden. The irregular distribution of the impurities makes calcination more difficult than in the case of the Austrian material. In the Canadian magnesite deposits, the distribution of the impurities is even more irregular. Calcium and silicon compounds should be removed as completely as possible as they reduce the melting point of the magnesite. Differences in the dead-burned magnesite from the different sources of magnesite are probably due chiefly to the conditions of burning and to the nature of the impurities present. A series of mixtures of iron oxide, alumina, and silica in the same proportions as those in which they occur as impurities in 13 different makes of magnesites had temperatures of incipient fusion remarkably close to 1100° C. The bulk of the magma in magnesite bricks corresponds to the average composition of the impurities, but some of the impurities form distinct compounds with the lime present. A notable difference between the impurities in bricks made of Grecian and Austrian magnesites is that in the former the magnesium silicates are much more bulky and highly viscous and do not penetrate the particles of magnesite so uniformly as in the latter. If bricks made of Grecian magnesite are fired 30 times at cone 30 the brown colour disappears, leaving a mass of pure white mineral with a micro-structure like that of Austrian bricks. On re-firing under normal commercial conditions, the brown colour reappears. Photo-micrographs show a much greater alteration in crystalline structure in Grecian bricks re-fired at 1750° C. than in those made of Austrian magnesite; hence, the latter are more durable in use. When re-fired at 1850° C., Grecian bricks show evidence of the segregation of impurity and local weakness, which would easily lead to rupture. In Austrian magnesite bricks the texture is remarkably uniform, the bricks consisting of even-sized particles not more than 1 in. in diameter and a magma which interpenetrates the particles much more uniformly than is the case with bricks made of Grecian magnesite. It is suggested that ferrous oxide or manganese added to the magnesite would act as a catalyst and secure the better conversion of the magnesite into large crystals as well as form definite mineral compounds of greater stability and density. Two types of magnesite brick are now made in Great Britain: one is of a finely ground material and weighs 72—76 cwt. per thousand, the other is a coarser material which weighs 82—86 cwt. per thousand and shows a greater difference in light and shade between the particles and magma. In both types a large proportion of the magnesite is in the calcined as distinct from the dead-burned state and the impurities surround rather than penetrate the particles as they do in the fully-dead-

burned Austrian bricks. The average sp. gr. of the British made bricks is only 3.435 as compared with 3.572 for the Austrian bricks, corresponding to a difference in weight of 10—15%. The chief faults of British magnesite bricks (which are mostly made of Grecian material) are spalling, especially in the roofs of electric furnaces where the bricks also tend to be deformed; inability to resist corrosion by basic slag, especially when porous; and crumbling to dust after 5 months' use in the bottoms of open-hearth and other furnaces, even when covered with a thick layer of rammed, sintered dolomite mixed with 10—20% of basic slag and tar as a binder. Austrian bricks are much better in these respects. Part of the weakness of the British bricks may be due to the ease with which they disintegrate when heated to 1200° C. under strong reducing conditions; at 1500° C. the disintegration is much less marked. When minute crystals of magnesite grow into larger ones, there is intense concentration with increased density, and therefore porosity between the various growths. If the growth could be secured before or during the burning of the bricks, the present objectionable shrinkage and spalling when the bricks are used in steel furnaces would be avoided. All magnesite bricks fall to a light powder when subjected to the action of steam. The crushing strength of magnesite bricks depends on the temperature and pressure at which they are burned and the nature of the impurities. The lower the porosity the greater the strength of the finished brick. The Austrian bricks are made under a pressure of 300 tons and British bricks are greatly improved by the use of a high pressure in moulding and a pressure of 15 lb. per sq. in. during burning. Improvements may be sought in prolonged heating of the magnesite under highly reducing conditions, and in the presence of a catalyst rather than by heating at excessively high temperatures. Selected Grecian material finely ground with a suitable proportion of ferrous carbonate could probably be dead-burned satisfactorily at 1400°—1500° C. in rotary kilns (as used in Austria), if they could withstand the necessary reducing atmosphere. In the Austrian material, the ferrous carbonate is present in a form isomorphous with the magnesite. Recent consignments from the Greek mines show that in the material which has been burned at 1750° C. in modern gas-fired shaft kilns, the requisite microstructural growth has taken place, though not quite regularly; it could probably be improved by greater care in grinding and burning. The British-made bricks of Grecian magnesite which behave most like the Austrian ones in furnace linings are those most closely corresponding in microstructure. Bricks can be made of Grecian magnesite under suitable conditions of heat and pressure, in which the formation of crystalline magnesite is complete, and they give better resistance to all temperatures up to 1750° C. and to corrosion by slag or attack by furnace atmosphere than Austrian bricks. If a pressure of 150 tons per brick is used in moulding them, the finished bricks weigh more than Austrian ones of the same dimensions, but have the same porosity (16%). This is more than sufficient to allow for thermal expansion in use without disrupting the bricks. It is considered that by the use of a suitable catalyst, bricks superior to the Austrian ones could be made commercially from Grecian or other relatively pure magnesite.—A. B. S.

Magnesite bricks; Micro-structure of —. A. Scott. Trans. Ceram. Soc., 1917, 17, 475—485.

COMMERCIAL calcined magnesite appears to be a very fine-grained amorphous mass of magnesite with local double refracting areas containing the im-

purities. Dead-burned magnesite contains crystals of periclase, and magnesite bricks show two well-defined types of structure. In the first type there are sharp polygonal crystals of periclase containing some isomorphous iron compound, not yet identified, which gives the crystals a well-defined cubic cleavage not possessed by pure periclase. The crystals are coloured red with disseminated iron oxide and contain inclusions of dark crystals of magnesioferrite (MgFe_2O_4). In the second type small rounded crystals of periclase are embedded in a crystalline matrix of low melting point and variable composition, containing a calcium silicate—monticellite (m.pt. 1460°C .), and possibly forsterite, together with another unidentified mineral. Crystals of the first type are found in bricks having iron oxide as the main impurity; those of the second type are more common in magnesite containing appreciable quantities of lime and silica, but some bricks contain both types of crystals. In the manufacture of magnesite bricks the first type is the more valuable, as the silicate matrix in the second type is too fusible an ingredient and should, if possible, be eliminated. The conversion of the amorphous magnesia into large-grain crystals of periclase is facilitated by silicious impurities, in presence of which the magnesia is dissolved, and re-precipitated as periclase. This increase in grain size results in an increase in the sp. gr. of the material, the amorphous magnesia corresponding to Mellor's α -form and the periclase to his β -form (this J., 1917, 551). Owing to the matrix facilitating crystallisation, it is difficult to discriminate the fragments of dead-burned magnesia in bricks which have been in use for a long time, as sections of them show a uniform structure.

—A. B. S.

Zirconia; its occurrence and application. H. C. Meyer. *Ceram. Soc., Refractories Sect.*, Oct. 18, 1918. [Advance proof.]

Zirconia occurs chiefly in the Calkas region, Brazil, as a mechanical mixture of brazilite, zircon, and an unnamed zirconium silicate readily soluble in hydrofluoric acid and containing about 75% ZrO_2 . Small briquettes, measuring $36 \times 20 \times 5$ mm., were made and burned at 1427°C . A briquette made of pure zirconia (99% ZrO_2) was quite soft after drying and when burned could be scratched with the finger nail. A briquette of water-ground ore containing about 84% ZrO_2 was extremely dense and hard. A briquette of partially purified material, containing about 95% ZrO_2 , was also very dense and hard. Another briquette made from 60 grms. of ore (80-mesh) and 40 grms. of water-ground ore had a linear shrinkage of only 3%, a rather coarse texture, and considerable tensile strength. Other briquettes made by ramming the material in the form of a "stiff mud" into a steel mould, drying, and then burning at 1600°C . gave the following results: Zirconia ore bonded with magnesium chloride solution of sp. gr. 1.23: showed no fusion, slight shrinkage, hardness greater than glass, very dense texture, great toughness; it was corroded by ferrous oxide. Zirconia ore bonded with water vapour gave similar results. A mixture of equal parts of zirconia ore and dead-burned magnesia bonded with magnesium chloride solution of sp. gr. 1.23 fused to a spongy mass of dark colour. A mixture of zirconia ore 10%, dead-burned magnesia 88%, magnesium chloride (sp. gr. 1.23) 2%, gave a light brown, hard and dense product, with sharp corners, no signs of fusion; it was not corroded by ferrous oxide. Zirconia ore bonded with water-glass of sp. gr. 1.26 gave an extremely hard, dense product, not fused, and slightly cracked. Briquettes made of zirconia ore (80-mesh), calcined magnesia, and water-ground zirconia ore had a

rather loose texture, but were resistant to abrasion and of fair tensile strength; when white hot could be dropped into water without damage. Full-sized bricks made of zirconia ore with 5% of fire-clay, burned in a silica brick kiln at 1640°C ., softened at a temperature well below the fusion point of the ore. After being in contact with carbon at 1800°C . for $1\frac{1}{2}$ hours, the surface was less affected than magnesia bricks, but more so than carborundum. A satisfactory commercial process for the manufacture of zirconia bricks consists in grinding the crushed ore to about 60-mesh in a dry pan. All particles finer than 100-mesh are removed and the coarser material is mixed with an equal weight of the fine water-ground ore, made into a stiff paste, and moulded in the same manner as silica bricks. The bricks are dried very slowly and are then burned. The percentage of loss due to cracked and warped bricks is rather high, but the damaged pieces may be reground.

Zirconia may also be used in combination with yttrium in Nernst glowers, as a substitute for lime in "magic" lanterns and in pencils for Blériot headlights, in the production of an acid-proof enamel, as an addition to fused silica ware to prevent devitrification, and as a substitute for bismuth salts in X-ray photography.—A. B. S.

Refractories; Electric furnace treatment of —. R. S. Hutton. *Trans. Ceram. Soc.*, 1917-18, 17, 233-243.

ELECTRIC furnaces have only been used to a relatively small extent in the manufacture of refractory materials. In the preparation of raw material, the chief advantage which electric furnace treatment can offer is in the facility with which fully shrunk material may be obtained and the ease with which some of it may be purified and so rendered more refractory. Where actual fusion of the refractory material is required a simple arc furnace will generally prove the most useful, but a resistance furnace is more efficient. In one series of trials about half a ton of highly shrunk magnesia was produced by completely embedding a vertical carbon rod 50 cm. long and 2 cm. diameter in the material to be heated, and passing a current of 400 amps. at 30 volts through the rod for 2 hours at a time. The energy consumption was only 1.17 kilowatt-hours per kilo. of shrunk magnesia. Only small articles can, at present, be burned in an electric furnace, but carbon plates coated with carborundum and held in graphite water-cooled terminals may form the basis of a larger technical furnace for use at 2000°C .—A. B. S.

Refractory materials; Relative volatilities of —. W. R. Mott. *Amer. Electrochem. Soc.*, Sep. 30—Oct. 2, 1918. [Advance copy.] 34 pages.

The apparatus used was a Helios photo-engraving lamp with a metal case having a pin-hole 12 in. from the arc, allowing the image of the arc to be projected on a suitable screen in a dark room, thus magnifying it 20 diameters. The arc required 25 amps. at 50 volts. The carbons were ordinary 12 in. $\times \frac{1}{2}$ in. high-grade solid enclosed arc carbons with an ash of 0.05-0.10%, the lower positive one having a cup-shaped hole ($\frac{3}{8} \times \frac{3}{8}$ in.) at its end. About 10 mgrms. of the refractory material was placed in the cup and heated for 3 minutes by the electric arc so that the vapour from the volatilised material travelled from the positive to the negative electrode. The deposits on the latter were arranged accurately in a position and in an order depending on their relative volatility. The results were compared with those from tungsten (b.pt. 6000°C .), and iron saturated with carbon (b.pt. 3500°C .). The

temperature of the positive crater of a carbon arc was taken as 3700°C .

Of ten methods tried, the most accurate was one of fractional distillation, though mixtures of lead and bismuth, tin and copper, and nickel and iron volatilised at practically the same temperature. This method is less satisfactory with metals in which carbon is soluble. With oxides, the experiments usually resolve themselves into a study of the order of reduction by carbon. On heating mixtures of various refractory materials with iron, the change from the iron arc to that of the refractory residue can be readily observed. Tungsten is left as a final residue when a mixture of it with any other material is distilled. Tungsten carbide decomposes into its constituents and the carbon volatilises. Next to tungsten tantalum is least volatile. Zirconium carbide is the least volatile carbide. The following oxides volatilise in the order given: K_2O , Na_2O , Li_2O , V_2O_5 , B_2O_3 , BaO , SrO , MnO , FeO , CoO , NiO , Cr_2O_3 , TiO_2 , V_2O_5 , SiO_2 , CaO , MgO , Al_2O_3 , Ti_2O_3 , V_2O_3 , Er_2O_3 , CeO_2 , Nd_2O_3 , La_2O_3 , BeO , Y_2O_3 , ZrO_2 , and ThO_2 last. The boiling points of the following refractory oxides were estimated from the distance in the arc image from the crater to the refractory material, this being roughly proportional to the volatility: BaO 2000°C , TiO_2 below 3000°C , Cr_2O_3 3000°C , CaO 3400°C , SiO_2 3500°C , MgO 3600°C , Al_2O_3 3800°C , and BeO 3900°C . Other boiling points, determined by fractional distillation of mixtures of the material with one of known boiling point, are: iron saturated with carbon 3500°C , palladium 3600°C , carbon 3700°C , chromium carbide 3800°C , vanadium carbide 3900°C , rhodium 4000°C , platinum 4050°C , uranium carbide 4100°C , ruthenium 4150°C , lanthanum oxide 4200°C , titanium carbide 4300°C , yttrium oxide 4300°C , columbium (niobium) carbide 4300°C , zirconium oxide 4300°C , thorium oxide 4400°C , iridium 4400°C , osmium 4450°C , molybdenum carbide 4500°C , yttrium carbide 4600°C , thorium carbide 5000°C , zirconium carbide 5100°C , tantalum (carbide?) 5500°C , and tungsten (carbide) 6000°C . Carbon sublimes at 3700°C and boron nitride at near 3000°C . The boiling point in absolute degrees divided by the melting point gives a ratio (average 1.8) which is similar for similar elements in the periodic table and characteristic of all elements except the alkali metals, the heaviest easily reduced elements, and the non-metals. A bibliography on the subject is included.—A. B. S.

Firebrick from the crown of an electric steel-melting furnace. W. J. Rees. Trans. Ceram. Soc., 1917-18, 17, 248-249.

A FIREBRICK from the crown of a $\frac{1}{2}$ -ton Greaves-Eichells electric steel-furnace which had lasted for 145 charges and had proved much more durable than silica brick, was made of a refractory bauxite clay from the Millstone Grit lavas of Ayrshire. The notable features of the brick are its high refractoriness (cone 37) and the proportions of silica (51.86%), alumina (28.7%), titanic oxide (6.68%), and iron oxide (1.56%) which it contains.—A. B. S.

[*Plaster pottery*] moulds; Deterioration of — during storage. J. W. Mellor. Trans. Ceram. Soc., 1917-18, 17, 331-335.

PLASTER moulds—especially those used in casting clay containing soluble salts—deteriorate and become "rotten" if stored in a damp state owing to the formation of crystals of sodium sulphate. To prevent this deterioration the moulds should be dried as rapidly and thoroughly as possible after

being used and should be stored in a dry place where no moisture can condense on them.—A. B. S.

Quaternary [pottery] mixtures; A method for the graphic determination of —. H. S. Newman. Trans. Ceram. Soc., 1917-18, 17, 336-339.

THE composition of a quaternary mixture may be graphically represented by the perpendicular distance of a point from the four sides of a square, and the author suggests that the composition of mixtures of ball clay, stone, china clay, and flint, as used by potters, may be represented by such a square diagram. No mixtures having more than 50% of any one constituent can be represented by such a diagram.—A. B. S.

Fritted glazes; Investigation of the solubility of lead in —. P. Bartel. Sprechsal, 1918, 51, 25, 31, 35, 39, 43. Z. angew. Chem., 1918, 31, Ref., 290.

THE author subjected frits with a composition ranging from $\text{PbO} \cdot 1.5\text{SiO}_2$ to $\text{PbO} \cdot 4\text{SiO}_2$ which had been ground to pass completely through a No. 175 sieve, to the action of 4% acetic acid under the conditions of the German official test for determining the solubility of lead in glazed ware (see this J., 1910, 354). It was found that the resistance of the glaze to the acid was not proportional to the silica content of the glaze, but that it increased with the silica content up to 2.5 mols. SiO_2 per mol. PbO and then diminished with more silicious glazes. On replacing a part of the lead oxide by soda, potash, lime, baryta, magnesia, or zinc oxide, less lead was dissolved by acetic acid. On the addition of alumina to the material used for the frits, the solubility of the lead was still further diminished and was reduced to *nil* in several frits containing either Na_2O , K_2O , CaO , BaO , MgO , or ZnO . Of the 817 frits examined, 430 yielded less than 2% of lead to the acetic acid solution; of these 11 were simple lead silicates containing alumina, 79 contained soda, 64 potash, 74 lime, 50 baryta, 85 magnesia, and 67 zinc oxide. Of these frits 14 contained 1.5 mols. SiO_2 ; 24, 1.75 SiO_2 ; 37, 2.0 SiO_2 ; 47, 2.25 SiO_2 ; 48, 2.5 SiO_2 ; 49, 2.75 SiO_2 ; 52, 3 SiO_2 ; 39, 3.25 SiO_2 ; 37, 3.5 SiO_2 ; 42, 3.75 SiO_2 ; 41, 4 SiO_2 . Most of the frits which contained 1.5 SiO_2 were clear, but those containing 2.75 or more SiO_2 were seldom so. The addition of boric acid to reduce the viscosity and the melting point of the frit was unsatisfactory.—A. B. S.

PATENTS.

Glass chemical ware [measuring cylinders, etc.]. A. Mond. London. Eng. Pat. 119,297, 3.10.17. (Appl. 14,293/17.)

GRADUATED measuring cylinders and the like are made of a glass tube of uniform bore fitted with a detachable plug or stopper which serves as a foot and may be removed to facilitate cleaning the vessels. The cost of grinding in the foot is compensated by the reduced cost of graduation.

—A. B. S.

Glass cylinders; Device for use in connection with the drawing of —. F. M. Francart, Springdale. Pat. U.S. Pat. 1,272,652, 16.7.18. Appl., 17.4.16.

THE tube through which the glass is drawn is provided with a skirt at its lower end and an inner annular recess or trap above the skirt, so that

when the tube is depressed into the glass around the drawing area, the surface impurities flow towards and are trapped in the recess.—A. B. S.

Glass; Manufacture of —. L. T. Sherwood, Connellsville, Pa. U.S. Pat. 1,277,493, 3.9.18. Appl., 18.11.16.

In the manufacture of glass from a batch containing nitre-cake, carbon is added in proportion amounting to at least 11% of the nitre-cake.

—A. B. S.

Silica bricks; Manufacture of —. Soc. Anon. des Prod. Refractaires de l'Onest, Paris. Eng. Pat. 118,116, 6.8.18. (Appl. 12,788/18.) Int. Conv., 6.8.17.

DISINTEGRATED or calcined quartz or quartzite containing 95% of silica is crushed, and part of it is then ground to flour, re-mixed with the crushed material in suitable proportions, and the mixture made into silica bricks in the customary manner.

—A. B. S.

Refractory bricks, blocks, tuyères and the like employed in connection with furnaces for smelting metals, etc.; Manufacture of —. H. E. Mason and A. Couper, Horwich. Eng. Pat. 119,101, 27.9.17. (Appl. 13,906/17.)

REFRACTORY blocks, etc. are made by mixing finely ground calcined magnesite with water and 6% of a fluxing agent such as basic slag, iron oxide, iron ore, metallic iron, or iron slag (either singly or mixed in any desired proportions) and 1% of a salt or salts of boric acid and/or perboric acid. Alternatively, the goods so made may be reduced to powder and re-made after the addition of water or other liquid, or raw magnesite may be used instead of the calcined material and the burned blocks may be ground and re-made. The fluxing agents and salts may be mixed, made into blocks and calcined; the product may then be ground to powder, mixed with calcined magnesite, and made into blocks, etc.—A. B. S.

Tunnel furnaces. E. E. Brand, Halsingborg, Sweden. Eng. Pat. 119,366, 2.1.18. (Appl. 14/18.)

Is a tunnel kiln having three compartments for preheating, heating, and cooling respectively, apertures are formed throughout the entire length of the roof and/or walls of the cooling chamber, through which air is forced at right angles to the customary current of air passing through the tunnel, thereby cooling the goods more effectively.—A. B. S.

Brick-kiln. E. H. A. Bollbuck, Los Angeles, Cal. U.S. Pat. 1,277,539, 3.9.18. Appl., 28.9.16.

A KILN is provided with stationary partitions fitted with doors so as to form a number of compartments which communicate in series and also, when the doors are opened, in parallel. Independent furnaces or burners on the top of the kiln communicate with the different compartments, and damper-controlled flues in the lower part of each compartment communicate with the main flues in the walls of the kiln.—A. B. S.

Refractory article and method of making same. S. C. Linbarger, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,277,227, 27.8.18. Appl., 22.3.18.

CRYSTALLINE silicon carbide is added to refractory mixtures of graphite and clay in order to lessen or prevent the formation of parting planes in the moulded mass.—A. B. S.

Enamelling metal articles and furnace therefor. P. Dupont, Paris. Eng. Pat. 114,618, 14.2.18. (Appl. 2667/18.) Int. Conv., 30.3.17.

A BATH or other article to be enamelled is placed in a furnace of similar shape, composed of very porous refractory material, covered externally with a metal casing, which is separated from it by a very narrow space. The furnace is heated by a mixture of gas and air preheated by the waste gases and injected into the space between the refractory material and the casing, and ignited on the inner surface of the refractory material by means of a series of independent burners. The products of combustion circulate between the refractory material and the article to be heated, and pass through two discharge passages, one in the base and the other in the cover of the furnace, to a supplementary furnace which is used for preheating the articles to be enamelled. The cover of the furnace is also of porous refractory material, but the angles are provided with pieces of non-porous refractory material. The refractory material is rapidly raised to incandescence and when the article to be enamelled has reached the requisite temperature, the cover is removed and the surface of the article is covered with powdered enamel. In an alternative arrangement, the refractory material may be much thinner and non-porous; it is then preferably strengthened by a metal casing and is heated by a series of burners, the flames from which burn in the space between this casing and an outer casing.—A. B. S.

IX.—BUILDING MATERIALS.

Cement; Elasticity of neat —. J. Jouane. Comptes rend., 1918, 167, 591—593.

To investigate the elasticity of mortars and concretes, prisms of the material are placed horizontally with one end fixed solidly in a wall or vice, the other being held in a clip suspended from a hook attached to the beam of a balance and carrying beneath it a funnel. The movements of the free end of the test-piece are shown by a mirror attached to the knife-edge of the balance. Sand flows into the funnel at a definite rate until a definite load is applied to the free end of the test-piece, after which the supply is cut off by an electrically controlled device which also opens a valve in the bottom of the funnel so that the sand flows out at the same rate as it had entered. In one experiment, a test-piece made of a mixture of 1000 grms. of cement and 350 grms. of water, measuring when air-dried, 38.6 cm. \times 2.96 cm. \times 1.43 cm. and weighing 286.07 grms., was subjected to loads gradually increasing to 500 grms. The deflections showed that with loads too small to produce permanent deformation the material has

a clearly marked coefficient of elasticity $E = \frac{Pl}{a^3bf}$

where P = load in kilos., f = corresponding deformation in cm., l = distance between the points of support at each end of the test-piece, a = breadth, and b = thickness of the test-piece. The elasticity was also determined by vibrating the test-piece and recording the oscillations (45.5 per sec.) on a smoked sheet. In this case

$$E = \frac{48d\pi^2N^2l^4}{a^2 \times 9.81 \times 10^5 \times \sqrt{1.87}}$$

in which d is the density in grms. per c.c., N = number of oscillations per sec., and l = distance between the fixed and free ends of the test-piece. The test-piece examined had a coefficient of elasticity of 1.080×10^5 kilos. per sq. cm. by the first

method and 1.074×10^5 kilos. per sq. cm. by the second one. Equally concordant results were obtained with other test-pieces.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Refractories used in steel production; Essential properties of —. A. Reynolds. Trans. Ceram. Soc., 1917—18, 17, 385—458.

THE author maintains that molten steel can be partially oxidised by silica and silicious slags, the resulting ferrous oxide causing segregation. In the production of steel the removal of each acid and base from the ore charge, including fluxes, should be a distinct metallurgical process, and the different stages should be conducted in separate furnaces, suited for one and unsuitable for another step. The use of silicious materials and clays in the production of casting nozzles and ladles should be avoided. The production and retention of perfect steel is impossible if it comes into contact with any material which is neither neutral nor basic, suitable neutral or basic materials must be found to take the place of the acid refractories now used. A further objection to acid linings for ladles, etc., in addition to their oxidising action, is that they become covered with manganese monosilicate which is rapidly "roasted" as the ladle is emptied and the manganese and iron oxides produced will spoil any steel which is next poured into the ladle. The reduction of the alkaline oxides in the refractory lining of a steel furnace at 1500°C . yields metals which are powerful catalytic agents and may bring about many unsuspected reactions, including the conversion of magnesia into an agent which oxidises steel and the possible nitrogenation of the steel. The presence of these oxides in refractories should, therefore, be avoided. Acid hearths have the advantage of providing for the rapid formation of silico-manganese (MnSi), which is one of the most powerful deoxidants, and thus produce better steels than basic furnaces. Basic refractories must be free from alkalis and from occluded oxygen. Alkalis in the form of silicates are undesirable, but less harmful than the alkaline

oxides. Acid silicates or silica should be absolutely excluded. Lime or dolomite is only admissible under such conditions of high temperature that it remains caustic. New refractories such as zirconia are useless unless their heats of formation are extremely high and their protoxides "unroastable." Improved magnesite bricks and neutral or basic aluminium and magnesium silicates are the most promising. They must be made from mixtures and treated so that at least the working face is free from acid portions. Thus, a mixture of fireclay and alumina would be very slightly less harmful than fireclay alone. The maximum temperature which such materials need to resist is somewhat below 1600°C . In the manufacture of crucible steel a three-pair equilibrium of slag-metal, slag-crucible, and metal-crucible may be obtained, but it is impossible to obtain the triple equilibrium slag-metal-crucible. The "cutting" of the crucible at the junction of metal and slag is therefore inevitable and its disastrous effects can only be avoided by using successively smaller charges of material each time the crucible is used. In newly built or repaired acid open hearths, the steel made from the first charge is of inferior quality, on account of the silicic acid in the hearth oxidising the iron in the charge. A series of new crucibles in which pieces of Swedish Bessemer ingot were melted showed clearly that the crucibles acted like an acid open hearth in catalytically oxidising some of the iron and absorbed a considerable proportion of manganese from the steel. The slag produced absorbed silica from the crucibles. In the proposed final process of deoxidation or "finishing" of the steel, by the addition of silico-manganese to the previously refined metal, the lining of the furnace should be nearly neutral or basic. Both the slag and lining must be quite inactive to iron and must therefore be as free as possible from iron or manganese silicates. A lining of aluminium monosilicate with a trace of alumina or of magnesium monosilicate would be refractory if rendered sufficiently basic, and it should be possible to prepare the latter from pure quartz and a magnesia which had been freed from iron, manganese, and alkalis by a wet process. Bricks, stoppers, and nozzles for such a furnace may be made of a mixture of fireclay and bauxite in the proportions required to form sillimanite and their surface fused in a special furnace (see Eng. Pat. 111,355; this J., 1918, 31A). Basic nozzles and stoppers are not satisfactory, as they do not remain caustic, readily decrepitate, and so spoil the steel, as the decrepitated matter is worse than slag in an ingot. Some refractories are unexpectedly volatile under reducing conditions at temperatures several hundred degrees below their normal softening point. Thus, the gas flues of two large producers were choked with a light feathery deposit containing 63% of silica. Several small crucibles made of kaolin and alumina in proportions to form aluminium monosilicate and others made of magnesite were buried in a loose carbon resistance furnace and charged with steel. They were heated slowly and all with the exception of one of the magnesite crucibles fumed away before the steel was molten (*i.e.*, below 1450°C). The old crucible withstood three treatments before it failed and appeared to be free from some unknown catalyst which was present in the others. The iron and manganese volatilised in electric arc furnaces form protoxides which attack the silicious roof of the furnace. The corresponding vapours in gas-fired furnaces form higher oxides which "season" and actually improve the roofs.—A. B. S.

Steel; Heterogeneity of —. H. Le Chatelier and B. Bogitch. Comptes rend., 1918, 167, 472—477.

THE polished surface of commercial steels, when attacked by suitable etching reagents, shows a

heterogeneous structure visible to the naked eye. This macrographic heterogeneity is unaltered by heat treatment, and Stead (this J., 1915, 616) attributed it chiefly to the unequal distribution of phosphorus. The authors' experiments lead to the view that the heterogeneity is entirely due to oxygen in solid solution in the steel, and that neither phosphorus nor sulphur has any direct influence. Electrolytic iron, with or without the addition of iron phosphide or sulphur, when melted in an atmosphere of hydrogen was homogeneous on etching, but the same metal, if melted with access of air, or with addition of iron oxide, showed a heterogeneous structure. If heated below its melting point the heterogeneity only occurred in the surface layers. In cast steels as the metal solidifying last will be the richest in oxygen, heterogeneity is particularly marked in segregated areas. The difference between the electrical resistance of steel as calculated from the chemical composition (which excludes oxygen), and as actually determined, is considered to be due to the influence of oxygen in the steel.—C. A. K.

Hardened steel; Spontaneous generation of heat in recently — C. F. Brush, R. A. Hadfield, and S. A. Main. *Proc. Roy. Soc.*, 1918, A, 95, 120—138.

In a previous paper (this J., 1917, 505) it was shown that a nickel-chrome steel hardened from 777°C. or above generated heat at a gradually decreasing rate for many hours. When, however, the metal was quenched from a temperature below the Ar1 point (from 532° to 667°C.), an absorption of heat resulted. Similar experiments carried out on a plain carbon steel showed a generation of heat after quenching from above the critical range but no generation or absorption of heat when the temperature of quenching was insufficient to result in the steel becoming hardened. A white iron showed a generation of heat after quenching from 757°C., but no trace of heat change was observed in the case of a pure Swedish charcoal iron. By replotting the results it is shown that the evolution or absorption of heat is greatest immediately after quenching and thereafter continuously decreases, so that: rate of evolution \times time after quenching = a constant. It is shown that the spontaneous contraction which occurs in hardened steel, given by the equation: $C_t = 159 \log_{10} T + 134$, where C_t is the linear contraction in millionths of the original length after T hours, is insufficient to produce all the heat evolved and it is suggested that a slow change goes on in the steel for a considerable time after quenching, and that both the evolution of heat and contraction are results of this change.

—F. C. Th.

Ferro-alloys [ferro-uranium]: Manufacture of — in the electric furnace. R. M. Keeney. *Amer. Inst. Min. Eng.*, Sep., 1918. *Chem. and Met. Eng.*, 1918, 19, 281—282.

ATTEMPTS to prepare ferro-uranium (20% U) direct from sodium uranate (the by-product of radium extraction), by adding to molten steel a mixture of the uranate with coke and fluorspar, resulted in the production of the double carbide, $\text{Fe}_2\text{C}_2\text{U}_2\text{C}_2$; and the latter could not be decarburised by means of silica or iron oxide, since the uranium was oxidised by these materials and passed into the slag. By heating sodium uranate to a high temperature with carbon in a stationary Siemens electric furnace having magnesite walls and a carbon bottom, a spongy metal containing over 90% U and 35—4% C was obtained. The recovery of uranium by this means was 50—60% in a single operation, and over 85% when the unreduced residue (uranium oxide and carbon) was re-treated with another charge; the power consumption averaged

about 8 kilowatt-hours per pound of metal. Attempts to prepare ferro-uranium by adding the spongy metal to molten steel were unsuccessful, owing to the oxidation of the uranium during the long time required to effect complete melting. By heating a mixture of uranium oxide, coke, and fluorspar with steel turnings in the Siemens furnace, ferro-uranium containing 50% U and less than 5% C was produced; and this alloy was successfully employed in the production of low-uranium steels (2—4% U).—W. E. F. P.

Copper; Relation of sulphur to overpoling of —. S. Skowronski. *Amer. Inst. Min. Eng.*, Sep., 1918. *Chem. and Met. Eng.*, 1918, 19, 279.

From experiments made with pure cathode and high-sulphur copper, it is concluded that the "pitch" of copper is affected by both oxygen and sulphur. Cuprous oxide counteracts the effect of sulphur by increasing the solubility of sulphur in copper, or by inducing a physical condition of equilibrium between the sulphur, tending to "overpole," and the cuprous oxide tending to "underpole" the metal. A comparatively large amount of cuprous oxide is required to counteract the effect of a trace of sulphur.—W. E. F. P.

Refractories in the zinc industry. J. A. Audley. *Ceram. Soc., Refractories Sect.*, Oct. 18, 1918. [Advance proof.]

THE chief requirements in retorts used in the zinc industry are refractoriness, resistance to dust and slag, mechanical strength and tenacity, resistance to sudden changes in temperature, low permeability to zinc vapours, and durability. Zinc is absorbed by the retort, especially by a new retort, with formation of blue zinc aluminate (spinel), the silica from the clay and also quartz grains present in the clay being partially converted into tridymite. Fraenkel (this J., 1909, 1254) considers that some zinc is lost in the form of a volatile ZnSSi which is not condensed in the receiver of the retort. Mühlhäuser found that the total loss of zinc in the case of new retorts diminished day by day in the following amounts: 32.35, 29.89, 20.97, 16.07, 16.97, 13.41, and 8.30% respectively. Iron compounds may be reduced to ferrous oxide or to metallic iron which may then form a slag having a highly corrosive action on the retorts. Manganese and lead silicates also corrode the retorts. Calcium and magnesium silicates alone are not very harmful, but in combination with ferrous and manganese silicates are highly corrosive. For this reason, the custom of adding lime to the charge has been discontinued. The retorts are usually made of a mixture of fire-clay and grog; they have a low thermal conductivity, will not withstand sudden changes in temperature, are readily attacked by materials in the charge, and are often sufficiently porous to allow zinc vapour to escape. A highly aluminous material, low in silica, would be preferable. In many Belgian works and in Spain the retorts are highly silicious, thinner, and of greater thermal conductivity, but they are less resistant to the corrosive action of the charge. In Belgium and Westphalia the retorts are sometimes glazed externally to render them impervious to zinc vapour. The prevailing temperature in the furnace when new retorts replace old ones is 1200°—1350°C., and as new retorts usually leave the furnace in which they are burned at 750°—780°C., they undergo a sudden rise of about 600°C. when placed in position; this tends to cause cracks, which later become healed by the action of dust from the furnace, though the material on either side of a crack is usually highly corroded. After being in the furnace for 24 hours, the exterior of the retorts is usually covered with a vitreous layer formed by

the action of dust on the retort, and small cavities (originating from the action of heat on iron oxide and other impurities) are produced. The temperature inside the retort, during the 24 hours after it has been charged, rises from 781° to 1188° C., being below 1050° C. for only about 7 hours. There is a difference of 286° C., gradually diminishing to 88° C., between the inside and the outside of the retort during distillation. After being in use for several days, the retort becomes very tough and elastic, but as the temperature falls, the strength decreases and the retort usually cracks during cooling. The lower part of a retort tends to have a higher specific gravity than the upper part (2.93:2.48), possibly due to the infiltration of materials capable of forming fusible silicates. The mouth of a retort is less heated than the remainder, the cracks thus formed being usually filled with sublimed zinc oxide. Micrographic examinations of used retorts show that the alumina in the clay is gradually converted into a zinc aluminate (spinell) containing about 1% of ferrous oxide, with a sp. gr. of 4.45–4.52, not attacked by any acid except boiling sulphuric acid. Quartz granules and some fragments of grog are found in the interior of the mass, together with about 50% tridymite and some willemite (zinc silicate). These changes do not reduce the refractoriness of the retort material. Incrustations on the retort usually consist of zinc oxide, with or without ferrous silicate, zinc plagioclase, and other silicates. Cavities in the retort material are usually filled with glassy silicates due to the action of portions of the charge on the retort and on each other. Modern improvements in the production of the retorts include the use of hydraulic shaping presses to increase the density of the material and so reduce the loss of zinc by absorption and permeability. Attempts to reduce the vapour pressure in the retorts have not been successful. The average life of hydraulically pressed retorts is about 40 days, and of hand-made retorts 25 days. Horizontal retorts are generally used, but vertical ones might shorten the time required for distillation, particularly if the charge were introduced in the form of briquettes. The use of magnesia for retorts and muffles has been suggested by Steger, on account of its greater thermal conductivity, greater resistance to corrosion, higher refractoriness, and impermeability to zinc vapour. The application of protective coatings of zirconia or fused alumina and the admixture of carborundum with the retort material are worth further attention, and the manufacture of retorts by casting may reduce their cost. For the median wall of the furnace, Mühlhäuser found red-brown bricks of St. Louis clay, which in the burned state contained 56.03% silica, 39.26% alumina, about 3% ferric oxide, and only small amounts of other metallic oxides, were suitable. He concluded that bricks burned at 100° C. higher than the maximum temperature of the portion of the furnace in which they are used will meet all demands.—A. B. S.

Monel metal. J. Arnott. *Engineering*, 1918, 106, 451.

The constituent metals of Monel metal are present in the proportions occurring in the original ore mined at Sudbury, Canada. Analyses of the rolled bar give approximately 66% Ni, 30% Cu, 3.5% Mn + Fe, 0.13% Si, with small amounts of phosphorus and sulphur; and metal for casting contains 1 to 1.5% Si. The structure of Monel metal is that of a solid solution, the rolled bar showing sharply defined crystal grains, usually twined. Mechanical tests on the rolled rod show a tensile strength of 39.2 tons; elongation on 2 in., 38.5%; reduction in area, 66.9%; Brinell hardness number, 174. When annealed at 800° C. the tensile test does not fall below 34 tons per sq. in., with a Brinell number of

143, and the strength is not dependent on the work applied. Monel metal possesses considerable strength at high temperatures; at 500° C., a temperature at which naval and manganese brass have no mechanical strength, the tensile strength is nearly 29 tons per sq. in. Casting of the metal is rendered difficult by the high melting point (about 1360° C.) and the excessive shrinkage.

—C. A. K.

Hardness [of metals]: Value of the indentation method in the determination of —. R. G. C. Bateson. *Inst. Mech. Eng.*, Oct. 18, 1918. [Advance copy.] 21 pages.

BENEDICKS' suggestion that the influence of the diameter of the ball in the Brinell test is eliminated by multiplying the value obtained by the fifth root of the radius of the ball is discredited. Brinell hardness numbers calculated from the depth of the impression are higher than those calculated from the diameter. Load-depth diagrams consist of an initial curve followed by a straight line, and the hardness number calculated from the slope of this line is independent of the load. If P and P_1 are the two pressures selected and d and d_1 the corresponding diameters of

impression, hardness no. = $\frac{16P.D^{n-2}}{\pi(2d)^n}$ where $n =$

$\log P_1 - \log P$. Further for a given angle of impression, preferably chosen such that the diameter of the impression is equal to half the diameter of the ball, the hardness No. = $\frac{4P}{\pi d^2}$, which is independent of the diameter of the ball. A measure of hardness with respect to dynamic stresses which is independent of the form of the indenting tool is given by

Energy of blow in kilogram-mètres

Vol. of indentation in c.c.

—F. C. Th.

Ludvik hardness test. W. C. Unwin. *Inst. Mech. Eng.*, Oct. 18, 1918. [Advance copy.] 8 pages.

Errors in indentation tests, such as the Brinell test, in which the indentations produced under different loads are not geometrically similar are obviated in the Ludvik test by the use of a right-angled cone instead of a ball. The hardness figures are then to a great extent independent of the load and also of the sharpness of the point of the cone, a truncated tool answering equally well. It is suggested that in the Brinell test the hardness

would be better defined as $\frac{P}{\pi a^2}$, where a is the radius of the impression instead of using the spherical area, and similarly in the Ludvik test. Under these conditions the Brinell and Ludvik tests would yield identical results.—F. C. Th.

Resistance of metals to penetration when tested by impact, and a new hardness scale in energy units. C. A. Edwards and F. W. Willis. *Proc. Inst. Mech. Eng.*, May, 1918, 335–367. (See also this J., 1918, 528 A.)

The following method is suggested for the determination of the hardness of metals at elevated temperatures up to 900° C. A 10 mm. Brinell ball rigidly attached to a free moving cross-head of known and variable weight drops a known distance on to the sample rigidly fixed to a heavy base. If d is the diameter in mm. of the indent produced, E the striking energy in inch-lb., and C a constant for each metal, $d = CE^{0.25}$. For a striking energy of 63 inch-lb. the ordinary Brinell hardness no. = $\frac{7455}{d^2}$, where d is the diameter of the indentation produced by the impact. The impact method of

measuring hardness eliminates the time factor, which is a source of uncertainty in the Brinell test as ordinarily carried out. It is considered that the estimation of hardness by the rebound of a hammer falling from a fixed height is unreliable, since different amounts of penetration are obtained in all tests.—F. C. Th.

Metals and alloys; Internal strains developed in — by rapid cooling. Portevin. *Comptes rend.*, 1918, 167, 531—533.

In the examination of the state of elastic equilibrium existing in metals after quenching, the method used by Heyn and Bauer (*Int. Zeits. Metall.*, 1911, 16—18; cf. this J., 1914, 596) was employed, successive layers of the metal being removed and the variation in length of the remaining piece being accurately measured. Solid and hollow cylinders of copper, nickel, brass, and steels were examined. The value of the stresses produced by quenching depends on the dimensions of the cylinder and the physical characteristics of the metal. The longitudinal stresses on a 20 mm. length gave a value of under 2 kilos. per sq. mm. for copper; for nickel, between - 10 and + 6 kilos. per sq. mm.; and for brass containing 60% Cu \pm 15 kilos. per sq. mm. A solid cylinder (70 mm. diam.) of semi-hard steel when quenched from 850° C., reheated to 550° C., and re-quenched in water gave a longitudinal compression of 14 kilos. per sq. mm. as against 27 kilos. when re-quenched from 700° C. For special work a certain rate of cooling may be adopted, sufficiently slow to avoid after-deformation, but on the other hand by too slow cooling certain steels (e.g. phosphoric and nickel-chromium steels) may fail on account of brittleness.—C. PATENTS.

Iron; Electro-deposition of —. F. A. Shepherd, and Brazil, Straker, and Co., Bristol. Eng. Pat. 119,200, 26.8.18. (Appl. 7074/18.)

As electrolyte for the electro-deposition of iron is prepared by boiling an aqueous solution containing 24 lb. of ferrous sulphate, 2½ lb. of ammonium chloride, and 18 lb. of iron filings in 11 gallons of water, and, whilst boiling, adding a solution of potassium bromide, 3 oz., boric acid, 2 oz., and common salt, 2 oz., in a gallon of water.—B. N.

Metals [iron]; Production of finely-divided —. T. A. Edison, Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 1,275,232, 13.8.18. Appl., 22.12.11.

Non-pyrophoric, electrolytically active iron, in a finely divided and highly porous condition, is prepared by reducing a suitable iron compound with hydrogen, and displacing the latter from the reduced metal by nitrogen before exposure to the atmosphere.—W. E. F. P.

Steel shapes; Process of treating —. J. Brunner, Evanston, Ill. U.S. Pat. 1,277,372, 3.9.18. Appl., 1.2.17.

STEEL shapes are rolled to a size rather greater than the required finished size, cooled below, and then reheated slightly above, the thermal critical range, and finally rolled to the finished size.—C. A. K.

Steel [; Cobalt-chromium —]. P. R. Kuehnrich, Sheffield. U.S. Pat. 1,277,431, 3.9.18. Appl., 17.10.16.

SEE Eng. Pat. 106,187 of 1916; this J., 1917, 886. The proportions of carbon and chromium specified are 1.2—3.5 and 8—20% respectively.

Magnetic iron product, and method of making same. T. D. Yensen, Swissvale, Pa. U.S. Pats. (A) 1,277,523 and (B) 1,277,524, 3.9.18. Appl., 6.3.16 and 11.6.17.

(A) MOLTEN refined iron in which the total content of phosphorus, sulphur, and manganese is less than 0.05%, and of carbon below 0.02%, is treated with a deoxidising agent *in vacuo* to reduce the oxygen content to 0.05%. The magnetic material thus obtained contains intercrystalline impurities aggregating less than 0.15% and has a magnetic permeability of 13,000—70,000 at a flux density between 5000 and 10,000 gauss. (B) An iron product containing at least 99.7% Fe, not more than 0.05% C, 0.05% O, and 0.05% Mn + P + S, with a saturation intensity of magnetisation of 1800—1850.—C. A. K.

Alloys containing nickel and zinc; Manufacture of —. Stabilimenti "Biak," A. Pouchain, Assignees of P. Peynetti, Turin, Italy. Eng. Pat. 113,272, 5.11.17. (Appl. 1710/18.) Int. Conv., 23.10.16.

In the preparation of a nickel-zinc alloy, the zinc is first heated in a closed vessel until vaporised; the temperature is then raised and the nickel is added, and "melted in the mass of zinc vapour."—C. A. K.

Electroplating apparatus. J. E. Evans-Jackson, London. From G. T. Potthoff, New York. Eng. Pat. 119,091, 20.9.17. (Appl. 13,547/17.)

A BARREL to hold the articles to be plated is mounted to rotate in a tank containing the plating solution. Means are provided for rotating the barrel for several revolutions in one direction, and then automatically several revolutions in the other direction. The barrel is brought to rest after each period of rotation, and when at rest the source of current is automatically disconnected from the conducting means leading to the anode and the cathode in the barrel. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 26,849 of 1904; this J., 1905, 1242.)—B. N.

Tungsten metal powder; Manufacture of —. O. Bertoya, London. Eng. Pat. 119,117, 15.10.17. (Appl. 14,915/17.)

THE reduction of tungsten trioxide to metal is effected by hydrogen or a gas containing hydrogen, which is injected under moderate pressure, not exceeding a few pounds per sq. in., into the lower ends of a number of inclined externally heated retorts, through which the tungsten trioxide passes in succession. Disturbance of the surface of the oxide constantly exposes fresh material to the action of the gas, and the descent of the charge is facilitated by the change in its physical character as reduction progresses.—T. H. B.

Gas [heating] furnace; Regenerative —. W. Topham, Patricroft, Laues. Eng. Pat. 119,273, 22.9.17. (Appl. 13,652/17.)

In a regenerative gas furnace for reheating ingots, billets, blooms, or the like for rolling or hammering, separate gas and air passages are provided for the two ends of the furnace, and are used alternately when the regenerators are reversed. The gas and

air conduits terminate in vertical portions on opposite sides of a wall, the outlets at the top of the wall being inclined towards one another so as to mix the hot gas and air in a chamber just behind a bridge member, over which the burning mixture passes into the furnace. The gas and air outlets are at a lower level than the top of the bridge. An auxiliary chamber is provided at the lower end of the vertical portion of the air conduit, in which solid matter may accumulate without obstructing the conduit, and holes are provided for its removal. To prevent overheating of the top of the wall where the mixture ignites, an air channel is provided within the wall.—W. F. F.

Electrodes; Metal — used in depositing and soldering by the electric arc. B. H. Jones, London. Eng. Pat. 119,279, 26.9.17. (Appl. 13,885/17.) Addn. to 14,468/15 (this J., 1916, 1222).

OTHER metals than mild steel may be used as base for the electrode, and are electroplated with another metal or metals.—B. N.

Metals [nickel and copper]; Separation of —. G. W. Pawet, Hudson Falls, and E. A. ReKate, Lancaster, N.Y., Assignors to United States Nickel Co., New Brunswick, N.J. U.S. Pat. 1,276,809, 27.8.18. Appl., 12.9.17.

RICH nickel-copper matte is roasted to remove the excess of sulphur, without affecting the sulphide sulphur, and is then mixed with about one-third of its weight of desulphurised copper obtained in a later stage of the process, finely ground, and agitated with hot strong sulphuric acid. The solution is evaporated and the nickel recovered by crystallisation. Copper and precious metals are recovered from part of the residue and the remainder is used to dilute the matte in an earlier stage of the process. Alternatively an easily soluble matte may be obtained by extensive bessemerising instead of by dilution.—T. H. B.

Alloy. F. S. Hodson, Philadelphia, Pa. U.S. Pat. 1,276,916, 27.8.18. Appl., 28.8.17.

AN alloy consisting of zinc, 80–85 parts, aluminium 18–14 parts, and copper 2–1 parts.—T. H. B.

Alloy. H. S. Cooper, Cleveland, Ohio, Assignor to The General Alloys Co. U.S. Pat. 1,277,046, 27.8.18. Appl., 17.4.18.

AN alloy, resistant to corrosion, consists of Ni over 50%, Zr 1 to 25, Al 1 to 12, Si 1 to 10, and W under 25%, the amounts of zirconium, aluminium, and silicon together being greater than that of tungsten, and the silicon and aluminium together greater than the zirconium.—T. St.

Ore concentration; Process of —. W. A. Scott, Chicago, Ill., Assignor to Minerals Separation North American Corporation. U.S. Pat. 1,276,974, 27.8.18. Appl., 15.12.16.

AN un aerated emulsion of an insoluble frothing agent in a comparatively small quantity of water is forced through fine orifices and added to an ore pulp, from which the metalliferous matter is then recovered by flotation with the aid of a gas.
—T. H. B.

Flotation process and apparatus. J. A. Pearce, Idaho Springs, Colo. U.S. Pat. 1,277,750, 3.9.18. Appl., 29.5.17.

A FLOTATION separating unit consists of an agitating compartment and a relatively deep flotation compartment communicating at the bottom. The flota-

tion compartment is provided with a froth overflow, and a separate tailings discharge at a lower level, which feeds the next agitation compartment in series. Pulp is fed into the top of the agitating compartment and is aerated and expelled into the bottom of the flotation section, so that the agitation section is normally practically empty and the flotation compartment full.—C. A. K.

Coating metals; Method of — [with lead]. Method of plating metal castings. R. J. Shoemaker, Milwaukee, Wis. U.S. Pats. (a) 1,276,977 and (b) 1,276,978, 27.8.18. Appls., 5.7 and 6.12.17.

(A) The article to be plated is introduced into a bath of molten lead through a layer of flux composed of 80% of zinc chloride and 20% of common salt. (B) The article is immersed in a bath of caustic soda and borax heated to a red heat and is afterwards introduced into a body of molten metal through a supernatant flux.—T. H. B.

Metallic coatings; Production of — by spraying finely-divided molten metal on moving objects. Metallatom Ges.m.b.H., Berlin-Tempelhof. Ger. Pats. (a) 307,378, 27.7 and (b) 307,406, 14.12.17.

(A) A NUMBER of articles to be coated with metal are placed in a rotary container so that they fall freely whilst exposed to the metallic vapour and particles from a spraying device. Openings are provided in the container for the removal of the excess of atomised metal. The spraying device is fixed at an angle at one end of the container and delivers the atomised metal the whole length of the container. A sand-blasting device may also be fitted to the apparatus. (B) The article to be sprayed with atomised metal is moved mechanically in such a manner that it is coated uniformly, or the sprayed material may be caused to rotate around the article. If the material to be coated is in the form of strips or wires, it is moved by suitable means through a closed rotating vessel, in which it is sprayed, the thickness and density of the coating being regulated by the time the material remains in contact with the metal spray and by the temperature inside the container; the wire or strip may also be passed between pressing devices. Several articles arranged parallel to each other may be moved and coated simultaneously; if desired the wires may be rotated at the same time as they are being coated and are passing longitudinally through the container.—A. B. S.

Crucible [for metal founding]. J. J. Boericke, Merion, Pa. U.S. Pat. 1,277,032, 27.8.18. Appl., 20.7.14. Renewed 29.6.18.

A CRUCIBLE is constructed in separate sections with a refractory friable continuous lining, permitting the ready exposure of the contents by removal of the separable portions.—C. A. K.

Metallurgical operations; Apparatus for carrying on —. J. J. Boericke, Merion, Pa. U.S. Pat. 1,277,033, 27.8.18. Appl., 20.7.14. Renewed 29.6.18.

AN enclosed chamber is divided into two connecting compartments by means of a battle-wall. One compartment is used as a reducing chamber, and is fitted with a door for the admission of a crucible (see preceding abstract). The other section serves as a fume-collecting compartment, and has a condensing flue opening from it. Material is admitted into the reducing chamber from a hopper by means of an externally controlled feed pipe.—C. A. K.

Metals; Method of producing — J. J. Boericke, Merion, Pa. U.S. Pats. (a) 1,277,034 and (b) 1,277,035, 27.8.18. Appl., 20.7.14. Renewed 29.6.18.

(a) METALLIC compounds are reduced by igniting a mixture of the metallic compound and a reducing agent (aluminium) and feeding a further quantity of the mixture on to the ignited material, so that the reaction is propagated in an upward direction and is under control. The reduction may be effected in a crucible of relatively large area to give access of air to the bulk of the mixture. (b) The process is modified by supplying the reducing agent in ingot or lump form.—C. A. K.

[*Copper;*] *Metallurgical process [for extraction of —]*. O. B. Dawson, El Paso, Tex., Assignor to Dawson Metallurgical Furnace Co. U.S. Pat. 1,277,047, 27.8.18. Appl., 11.7.17.

OXIDISED copper ore is heated in the presence of air to just below the melting point of copper, and sufficient carbon is then added to reduce the charge and to liberate enough carbon monoxide to provide the heat necessary to melt the metal formed. The liberated carbon monoxide is maintained at a pressure above atmospheric, and the charge is agitated to assist reduction and cause the metal particles to agglomerate. The mass is finally discharged into an atmosphere of water vapour to prevent re-oxidation, and the metal separated from the gangue.—T. St.

Converter; Small — with side tuyères and provision for the removal of slag. C. Raapke, Güstrow, Ger. Pat. 307,332, 18.1.18.

A SICKLE-SHAPED niche is made in the lining of a converter opposite the tuyères, in such a position as to compel the slag to follow a circular path and to remain in the converter. The slag retained in the niche, being protected from the action of the molten metal and the gases, does not absorb iron or silica, and so does not become excessively fluid and prevent the regular escape of the gases which—with thin slags—are liable to spurt badly. The retention of the slag within the cupola also retains more heat in the iron and facilitates the removal of gases from the metal.—A. R. S.

Blast furnaces; Charging apparatus for —. Blast Furnaces and Equipment, Ltd., and F. Ritson, London. Eng. Pat. 119,504, 28.9.17. (Appl. 14,023/17.)

Alloys. F. S. Hodson, Golder's Green. Eng. Pat. 119,486, 16.7.17. (Appl. 10,276/17.)

SEE U.S. Pat. 1,276,916 of 1918; preceding.

Refractory bricks, etc. Eng. Pat. 119,101. See VIII.

XI.—ELECTRO-CHEMISTRY.

Electrostatic precipitation. O. H. Eschholz. Amer. Inst. Min. Eng., Sep., 1918. Chem. and Met. Eng., 1918, 19, 285—286.

IN practically all commercial plants for electrostatic precipitation, the mechanical rectifier is still employed for converting high-tension alternating into high-tension unidirectional current. In this apparatus a positive separation is made between the alternating current supplied and the unidirectional impulses sent to the electrostatic treater. By reason of the comparatively slow rate of discharge, the voltage across the treater is practically constant. Systems depending on the use of mechanical rectifiers are classified according to the source of power, that considered most satisfactory being one in which the power for a single transformer-rectifier-treater unit is obtained from a low-tension, single-phase, alternating-current generator for treater load only. The apparent advantage of low first cost is illusory, since the whole cost of the electrical equipment is only 10—15% of the cost of the treater and 2—7% of the value of the yearly recovery.—W. E. F. P.

Refractories. Hutton. See VIII.

PATENTS.

Electrolytic cells, adapted for the manufacture of caustic alkali from sodium chloride. N. Statham, Hastings-on-Hudson, N.Y., U.S.A. Eng. Pat. 118,355, 26.9.17. (Appl. 13,884/17.)

IN an electrolytic cell of the diaphragm or Hargreaves type the diaphragm is provided on its outer side with relatively impervious material of varying thickness, so as to allow substantially uniform percolation of the electrolyte through the diaphragm at different heights, and at such a rate that back diffusion from the cathode chamber is prevented. Good results are obtained when the cathode electrolyte contains substantially equal proportions of electrolytically-produced caustic soda and undecomposed salt, or a slightly greater amount of the former substance. (Reference is directed, in pursuance of Sec. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 5197 of 1893, 20,889 of 1903, and 27,830 of 1907; this J., 1894, 528; 1904, 24; 1909, 96.)—B. N.

Accumulators; Electric — or secondary batteries. F. La Roche, Hampstead. Eng. Pat. 119,100, 26.9.17. (Appl. 12,853/17.)

AN electrode for secondary batteries is composed of about 75% of lead, 15% of nickel, and 10% of silver or cadmium, cast in one piece, with a ribbed surface and raised edge, with or without lugs or terminals.—B. N.

Carbon electrodes; Method of transforming by heating in an electric furnace, anthracite, coke, and other materials rich in carbon into a product suitable for the manufacture of —. S. E. Sienrin, Hôganås, Sweden. Eng. Pat. 119,164, 15.12.17. (Appl. 18,689/17.)

ANTHRACITE, coke, or other material rich in carbon is transformed into a product suitable for the manufacture of carbon electrodes by heating the material in an electric resistance furnace to 1800° to 2000° C., i.e. to a temperature approaching but not reaching that at which transformation of the carbon into graphite takes place. A suitable furnace consists of a casing of fireproof material with a vertical cylindrical cavity for the charge. The upper

electrode passes through the top of the furnace, and around it are channels for the supply of material. The bottom of the furnace consists of the lower electrode, through which is a cavity for removal of the charge. The furnace works as a resistance furnace, in which the charge itself forms the resistance.—L. A. C.

Electric furnaces; Construction of — of the heated coil type. J. E. P. Kievits, and Kynoch, Ltd., Birmingham. Eng. Pat. 119,302, 13.10.17. (Appl. 14,888/17.)

The heating coil is made from a wire formed into a close spiral and then wound round a tube of refractory material, the coils being embedded in cement. The spiral of wire is covered with paper or like substance, to prevent the cement obtaining ingress to the interior of the spiral, and the paper is subsequently burnt off whilst a current of air is being blown through the spiral passage.—B. N.

Electric furnaces; Electrode holders for —. A./S. Arendal Smelteverk, Eydehavn, Norway. Eng. Pat. 114,841, 5.4.18. (Appl. 5866/18.) Int. Conv. 13.4.17.

Storage battery plates; Separators for —. W. Morrison, Chicago, U.S.A. Eng. Pat. 111,469, 16.10. and 114,816, 25.9.17. (Appls. 14,979 and 13,786/17.) Int. Conv. 11.11.16 and 2.4.17.

XII.—FATS; OILS; WAXES.

Oil of red salmon, oil of "abura-garei," and liver oil of "chô-no-fuyé." S. Nakatogawa, Kôgyô-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 411—414.

Oil obtained from the body of the red salmon (*Oncorhynchus nerka*) had a reddish-orange colour, and remained fluid at -10°C . After refining with kambara earth it had the following characters:—Sp. gr. ($15^{\circ}/1^{\circ}\text{C}$.), 0.9248; acid value, 7.4; saponif. value, 186.1; iodine value (Wijs), 148.1; $n_D^{20}=1.4775$; m.pt. of fatty acids, 26.2° — 28.5°C .; and insoluble bromides, 38.9%. Two samples of oil of abura-garei (a species of flat fish, *Gymnosella dubia*, found off the Japanese coast) had the following characters:—Sp. gr. ($15^{\circ}/1^{\circ}\text{C}$.), 0.9181, 0.9172; acid value, 6.1, 3.8; saponif. value, 182.9, 187.1; iodine value (Wijs), 95.8, 94.9; $n_D^{20}=1.4725$, 1.4730; m.pt. of fatty acids (one sample), 19° — 21°C .; and insol. polybromides (one sample), 10.91%. This oil is suitable for the manufacture of hardened oils. The liver of "Chô-no-fuyé," *Carlotrhynchus japonicus*, a kind of cod, yields about 12% of oil of a brownish-yellow colour. It deposits "stearine" on standing. A sample from the coast of Izu, Japan, had the following characters:—Sp. gr. ($15^{\circ}/4^{\circ}\text{C}$.), 0.9254; acid value, 2.1; saponif. value, 187.7; iodine value, 129.57; and $n_D^{20}=1.4761$. It did not contain the hydrocarbon squalene, $\text{C}_{30}\text{H}_{50}$.—C. A. M.

Apricot kernel oils; Mongolian and Chinese —. S. Ueno, Kôgyô-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 525—527.

The kernels of the Mongolian apricot seeds (*Prunus armeniaca*, L.) contained 54% of oil, which, when extracted with ether, had the following characters: Sp. gr. at $15^{\circ}/4^{\circ}\text{C}$., 0.9187; acid value, 0.7; saponif. value, 188.6; iodine value (Wijs), 105.4; and $n_D^{20}=1.4723$. The kernels of the Chinese apricot (*P. armeniaca*, L.) contained 53% of oil with the following characters:—Sp. gr. at $15^{\circ}/4^{\circ}\text{C}$., 0.9101; acid value, 3.75; saponif. value, 182.3; iodine value (Wijs), 90.4; Hehner value, 95.7; Reichert-Meißl value, 0.7; and $n_D^{20}=1.4659$.—C. A. M.

Calcium soaps; Direct determination of — by means of solvents. E. Salm and S. Prager. Chem.-Zeit., 1918, 42, 463—464.

CALCIUM soaps prepared from bone-fat, glue-leather fat, neat's-foot oil, linseed oil, and castor oil were extracted for 16 hours with various solvents, and the amount of extract determined. In all cases the soap swelled up into a gelatinous mass when heated with petroleum spirit, carbon bisulphide, benzene, or carbon tetrachloride, but not with acetone or ether, so that concordant results were obtained with the latter solvents. With the exception of castor oil calcium soap (solubility 92.2%) all the soaps dissolved with difficulty in acetone. Ether had a greater solvent action than acetone, especially in the case of the neat's-foot oil and linseed oil soaps. Hence acetone should be used rather than ether for separating neutral fats from calcium soaps. The calcium salts of bone-fat and glue-leather fat are readily soluble in benzene and carbon tetrachloride, and one of these solvents should be used instead of ether or acetone for extracting the total fat, including calcium soaps, from fatty material containing such soaps, provided that the material does not swell up in the treatment. The solubility of calcium soaps in benzene increases with the temperature, and is complete at the boiling point of the solvent after about 6 hours' extraction in a Besson flask. Moisture reduces the solubility, so that the material should first be dried at 95° to 100°C . The results thus obtained agree closely with those given by Fahrion's method (this J., 1899, 712).—C. A. M.

Fatty acids; New method for the accurate estimation of the content of — in soaps. E. Bosshard and F. Comte. Helv. Chim. Acta, 1918, 1, 251—270.

Errors are introduced in the estimation of fatty acids in soaps when these are weighed as such, owing partly to oxidation of the unsaturated acids and partly to the volatility of the lower fatty acids. The authors weigh them as the lead salts. A well-stoppered 100 c.c. Erlenmeyer flask is charged with about 5 grms. of lead oxide and a few pieces of pumice (dried at 100°C .), about 1 gm. of a fatty acid, and 30 c.c. of ether or petroleum spirit (or a mixture of the two) are added, the flask is shaken vigorously, and the solvent is removed by evaporation at 60°C . (chloroform bath) or 107°C . (toluene bath), at first under slightly reduced pressure to prevent foaming, and finally, when the solvent has disappeared, at 12 mm. pressure until the weight is constant (usually after about 20 minutes). From the equation $2\text{R}\cdot\text{COOH} + \text{PbO} = (\text{R}\cdot\text{COO})_2\text{Pb} + \text{H}_2\text{O}$, it is evident that the increase in the weight of the flask and its contents represents the weight of the acid anhydride; the weight of the acid is obtained by multiplying by the requisite factor. Examples are given in the case of individual acids showing that the method is trustworthy. When ascertaining the percentage of a mixture of fatty acids, the

mean molecular weight of the mixture must be determined. The method gives satisfactory results with the mixtures of acids obtained by hydrolysing natural oils, soaps, and colophony. The hydrolysis is effected in a Huggenberg and Stadlinger saponometer. The soap (4–6 grms., or 10 grms. in the case of a soft soap) is dissolved in hot water and introduced into the saponometer which contains 25–30 c.c. of N/1 sulphuric acid (a slight excess) and a few drops of methyl orange. Water is added to the mark 100, and, after sufficiently cooling, about 50 c.c. of a mixture of equal parts of ether and petroleum spirit. The mixture is shaken vigorously. 50 c.c. of the ether-petroleum spirit mixture is added, the mixture is again shaken, the acid layer is run off, and the ethereal solution, after being washed with 100 c.c. of water, is removed, and an aliquot part, about 25 c.c., is treated with lead oxide as described above.—C. S.

PATENTS.

Oil press. P. Zumberg and J. Sardin, Detroit, Mich. U.S. Pat. 1,277,677, 3.9.18. Appl., 18.4.18.

An outer casing with horizontal openings through its walls is secured to an inner casing with vertical slots through its walls. The casings are made in two halves and the outer halves can be rigidly secured round the inner casing.—J. H. P.

Fatty acid esters; Forming and hydrogenating —. C. Ellis, Montclair, N.J. U.S. Pat. 1,277,708, 3.9.18. Appl., 28.9.6.

UNSATURATED free fatty acid (oleic acid) present in fatty oils is esterified by heating the oil with an alcohol (ethyl alcohol), and the product is then treated with hydrogen in the presence of a hydrogenating catalyst.—L. A. C.

Soap and process of making the same. O. Ludekens, Assignor to the Wite-Kat Soap Co., San Francisco, Cal. U.S. Pat. 1,276,383, 20.8.18. Appl., 23.7.17.

A hot aqueous solution of soap is mixed with a substance, such as beeswax or "para wax," capable of forming an envelope enclosing minute particles of the liquid, and the mixture agitated, with or without aeration, to reduce it to the form of a paste.—C. A. M.

PATENTS.

Gas-black, hydrogen, etc.; Process for manufacturing —. C. D. McCourt, London, and C. Ellis, Montclair, N.J., Assignors to Surface Combustion, Inc., Wilmington, Del. U.S. Pat. 1,276,385, 20.8.18. Appl., 23.1.12.

METHANE is forced through a bed of strongly-heated, porous, refractory material, the resulting gas-black separated from the hydrogen, and the latter burned to maintain the heat of the bed.—C. A. M.

Phenolic condensation products; Manufacture of —. H. Wade, London. From Redmanol Chemical Products Co., Chicago, U.S.A. Eng. Pats. 119,252 and 119,253, 25.7.17. (Appls. 10,705 and 10,706/17.)

SEE U.S. Pats. 1,242,593 and 1,242,592 of 1917; this J., 1917, 1242.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

[Rubber] latex coagulation; Theory of —. G. S. Whitby, Agric. Bull. Fed. Malay States, 1918, 6, 374–384.

THE phenomena of the coagulation of latex are compared with those of the clotting of milk, and the conclusion is drawn that with Hevea latex the coagulation in the presence of small amounts of acetic acid is more closely analogous with the clotting of milk by rennin than by the effect of acids or natural souring. With milk there is a critical concentration of acid below which both lactic acid and acetic acid not only fail to effect coagulation but indeed exert an anti-coagulating effect as compared with untreated milk; this peculiarity is probably due to the acids exerting an inhibitive influence on the growth of the lactic acid bacterium, and is in marked contrast with their coagulating effect on Hevea latex at all concentrations. The clotting of milk by acids is almost instantaneous, whereas the coagulation of Hevea latex under similar conditions may require from several minutes to several hours, the rate being comparable with that of the reaction between milk and rennin. The coherent clot in the last case also more closely resembles ordinary rubber coagulum than does the flocculent precipitate from acidified milk. The "natural" coagulation of Hevea latex is not a simple function of the acidity which is produced by bacterial action, and coagulation by heating or by tannic acid yields a flocculent or non-coherent coagulum analogous with that produced on acidifying milk. Rennin is activated by the presence of calcium salts and the influence of calcium salts on the "natural" coagulation of latex is probably of a similar nature. Bactericides, such as toluene or thymol, which are harmless to most enzymes, do not inhibit natural coagulation of latex, whereas hydrocyanic acid and potassium cyanide, which "paralyse" enzymes, prevent coagulation. Although small quantities of hydrochloric or nitric acid favour the coagulation of latex, with larger quantities a "neutral point" is reached at which no effect is produced, and still larger quantities again cause coagulation; this neutral point is attributable to the paralysis or destruction of the enzyme by acid at that particular concentration. The evidence of Eaton and Grantham (this J., 1916, 263) in support of their view that natural coagulation is due to lactic acid produced by bacterial action is not inconsistent with the enzyme theory. The initial formation of a coagulum in fresh latex allowed to undergo natural change is therefore regarded as due to enzyme action and the same agency, activated by acids, is probably responsible for the usual coagulation in the presence of small quantities of acetic acid (see also Barrowcliff, this J., 1918, 481). Bacterial action even in natural coagulation is only a secondary factor. Under unusual conditions, other types of coagulation may occur, e.g. delayed coagulation due to the putrefactive decomposition of latex which has previously been sterilised, and the formation of non-coherent coagula under the action of heat or of such substances as tannic acid, which are precipitants for the protein of the latex.—D. F. T.

Destructive distillation of the beads of automobile tyres. A. Dubosc. Caoutchouc et Gutta Percha, 1918, 15, 9617—9619.

BEADS of automobile covers, after removal of all but the last layer of fabric, were cut into fragments and heated in an iron retort, provided with a thermometer. The issuing gases and vapours were passed through an ice-cooled condenser into a measured volume of water. The products included a residue of 52%, oil 28.99%, water 8.33%, and gases (by difference) 10.68%; the residue consisted of carbon (10.92%) and mineral substances (41.08%), including zinc oxide, litharge, calcium carbonate, magnesia, and insoluble matter; the condensed liquids contained acetic acid, benzene, toluene, xylenes, ethylbenzene, and dipentene, but no isoprene or heveene; the gases were hydrogen sulphide and acetylene. Decomposition commenced to be vigorous between 75° and 145° C. and was complete at 245° C.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin solutions; Influence of electrolytes upon the osmotic pressure of —. J. Loeb. J. Biol. Chem., 1918, 35, 497—508.

THE influence of electrolytes upon the osmotic pressure of gelatin runs parallel to the influence exerted on the swelling, viscosity, and precipitation by alcohol (see this J., 1918, 383A, 384A, 520A). —H. W. B.

PATENTS.

Skins; Method and apparatus for drying —. J. U. Flanagan, Assignor to F. F. Slocomb and Co., Wilmington, Del. U.S. Pat. 1,273,598, 23.7.18. Appl., 13.1.14.

SKINS are suspended, doubled, in a closed chamber, into which heated air enters, under pressure, through inlets exactly under the open spaces between the doubled parts of the skins. The air passes out into an exhaust chamber.—F. C. T.

Tanning. J. K. Tullis, Paris. Eng. Pat. 117,922, 6.7.17. (Appl. 8912/17.)

HIDES are first partly chrome tanned by any ordinary process, or simply immersed in a solution of sodium bichromate, after which the tanning is completed by treating the hides with a solution of wood pulp extract, either alone or in conjunction with any of the usual vegetable tanning materials or extracts.—F. C. T.

Tanning of hides and skins. B. Levin, Hale, Cheshire. Eng. Pat. 117,941, 7.8.17. (Appl. 11,347/17.)

HIDES and skins after cleaning, etc., are first treated with a solution of alum, or other soluble aluminium compound, and then with a solution of sodium pyrophosphate in sufficient quantity to convert the aluminium compound in the pores of the hides into insoluble aluminium pyrophosphate.—F. C. T.

Tanning; Process of —. W. Petrie, Endicott, N.Y., Assignor to Petrie Process Co., New York. U.S. Pat. 1,273,662, 23.7.18. Appl., 2.4.17.

HIDES are agitated, e.g. in a rotary drum, with a small quantity of concentrated tanning liquor. Air has free access to the hides, and the liquor is renewed as it is absorbed.—F. C. T.

Leather; Manufacture of —. A. Obser, Newark, N.J. U.S. Pat. 1,268,876, 11.6.18. Appl., 18.4.17.

HIDES are given a preliminary tannage in a bark liquor and are then split. The splits are pickled and subsequently subjected to mineral tannage. The leather is finally neutralised, washed, and finished. For stuffing the leather a fat liquor is used consisting of salt, fat, cottonseed oil, and moccion.

—F. C. T.

[Leather] product; Indurated —. J. McIntosh, Morristown, Pa., Assignor to Diamond State Fibre Co., Bridgeport, Pa. U.S. Pat. 1,269,292, 11.6.18. Appl., 26.1.17.

THE claim is for leather or animal membrane impregnated with solid synthetic resin or condensate. (See U.S. Pat. 1,236,460 of 1917; this J., 1917, 1092.) —F. C. T.

Leather; Substitute for — and process of and apparatus for manufacturing the same. J. Ward, Bedford. Eng. Pat. 119,304, 16.10.17. (Appl. 14,982/17.)

LEATHER scrap or waste is roasted in a hot air kiln until crisp, ground into powder, and mixed with vulcanised rubber previously worked up into a fine powder. Sulphur is added to the mixture, also resin and sodium silicate if required, the mixture being heated to convert it into a semi-liquid state, in which form it is applied to coarse felt to coat the surface and impregnate the material.—B. N.

Leather; Process of producing artificial —. T. J. Turner, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,269,339, 11.6.18. Appl., 3.9.14. Renewed 19.12.17.

A FABRIC is coated with a plastic nitrocellulose composition by means of calender rolls.—F. C. T.

Leather; Artificial — and means of producing the same. W. W. Richards, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,270,055, 18.6.18. Appl., 16.11.12.

A FABRIC is coated with pyroxylin to which has been added an essential oil, musk, or animal oil, or all of these.—F. C. T.

Artificial leather; Process of producing —. C. E. Arnold, Wilmington, Del., Assignor to E. I. du Pont de Nemours and Co. U.S. Pat. 1,277,528, 3.9.18. Appl., 3.9.14.

A COATING of a viscous (pasty) solution of nitrocellulose is applied to a fabric, and after partial evaporation of the solvent the coated fabric is passed between rolls to give the desired thickness. —C. A. K.

Leather; Method of drying varnished patent —. E. Hintz, Wiesbaden, Assignor to C. Heyl, Worms, Germany. U.S. Pat. 1,269,931, 18.6.18. Appl., 12.12.16.

VARNISHED (patent) leather is exposed to the action of light of short wave length only and rich in ultra-violet rays, and at the same time all air or other oxidising agent is excluded.—F. C. T.

Tannery waste disposal process. H. W. Taylor, New York. U.S. Pat. 1,277,776, 3.9.18. Appl., 28.11.16.

TANNERY waste liquors are separated into three classes, i.e., tanning wastes, liming wastes, and miscellaneous waters. The tanning wastes and liming waste are mixed in such proportion that

the resulting liquor is just neutral, and the precipitate formed is filtered off. The liquor is then added to the miscellaneous waste liquor and the mixture treated with a suitable precipitant, *i.e.*, iron sulphate.—L. A. C.

Gelatin; Process for preparing —. T. Tada, Tokushima Ken, Japan. U.S. Pat. 1,271,960, 9.7.18. Appl., 1.6.18.

A solution of gelatin, bleached and clarified, is concentrated *in vacuo* to 30–60% strength, allowed to set in thin sheets in moulds, and subsequently dried at a temperature not lower than 40° C.

—F. C. T.

Gelatin; Process for preparing —. T. Tada, Tokushima, Japan. Eng. Pat. 119,210, 3.6.18. (Appl. 9144/18.)

SEE U.S. Pat. 1,271,960 of 1918; preceding.

XVI.—SOILS; FERTILISERS.

Azotobacter; Soil reaction and the growth of —. P. L. Gainey. J. Agric. Res., 1918, 14, 265–271.

NEARLY a hundred samples of soils from widely different sources, both cultivated and uncultivated, were examined for the presence of azotobacter. 28% of the samples gave the typical azotobacter growth, with a fixation of nitrogen of 9.47 mgrms. per culture. In 41% no azotobacter were found, and these soils fixed 3.88 mgrms. of nitrogen on the average. The other soils gave a mixed growth. The presence or absence of azotobacter had no regular relation with any of the conditions of the soils, except possibly that of the hydrogen-ion concentration. Soils in which this factor was less than P_{H6} contained no azotobacter; those above P_{H6} contained azotobacter.—J. H. J.

Calcium cyanamide; Alteration of — on storage. J. P. van Zyl. Z. angew. Chem., 1918, 31, 203–204.

THE author has examined a sample of calcium cyanamide which had lain exposed on the floor of a barn for 2½ years. The original material was stated to have contained 19% of total nitrogen; the sample after storage showed 14.64%. The residue insoluble in boiling water contained 1.32% of nitrogen; the aqueous extract was analysed by Caro's method and showed 131.3 mgrms. of total nitrogen per grm. of the sample, comprising 99.5 mgrms. in the form of cyanamide, 2.1 as dicyanodiamide, 10 as ammonia, and the rest presumably in the form of urea. It appears remarkable that after storage for 2½ years without special precautions, the freshness of the cyanamide should have been so well preserved, in view of the fact that Kappen had found a total disappearance of cyanamide from an old sample and the conversion of 75% of the nitrogen into dicyanodiamide.—J. F. B.

PATENTS.

Superphosphate; Apparatus for the manufacture of —. G. A. Mower and F. W. R. Williams, London. Eng. Pat. 119,074, 17.9.17. (Appl. 13,334/17.)

THE mixture of phosphate and acid is placed in a movable truck having a removable front wall, side walls hinged at the top, and closed at the bottom by a stationary bed upon which the block of superphosphate remains when the reaction is completed. The front wall of the truck is then removed, and rotary cutters attached to the truck are maintained in contact with the exposed surface by moving the superstructure relatively to the base.—W. E. F. P.

Fertiliser materials; Process of producing —. T. C. Meadows, Assignor to Kaolin Products Corporation, New York. U.S. Pat. 1,276,555, 20.8.18. Appl., 8.12.16.

“GREEN SAND” (a deposit of fine or coarse sands, mixed with varying quantities of glauconite, forming a subdivision of the Cretaceous system) containing a substantial proportion of glauconite is calcined to convert the iron into the ferrie state, finely ground, and mixed with water to form a sludge. Commercial mono- and di-calcium phosphates are added to the sludge, which is then digested at a pressure above three atmospheres until mono- and di-potassium phosphates are formed.—J. H. J.

Calcium cyanamide; Process for granululating —. G. W. Sinclair, Petersham. U.S. Pat. 1,278,041, 3.9.18. Appl., 19.12.16.

SEE Eng. Pat. 105,578 of 1916; this J., 1917, 607.

XVII.—SUGARS; STARCHES; GUMS.

Sugar losses in manufacture. L. Fauque. Bull. Soc. Chim. Maurice, 1918, 9, 45–47. Int. Sugar J., 1918, 20, 477–478.

THE theoretical extraction of first jet sugar is given by the formula: $\frac{P-P'}{P(100-P')}$, in which P represents the purity of the syrup in course of working, and P' that of the exhausted syrup. The difference between the calculated extraction and the sugar contained in the syrup represents the loss in the molasses, and that between the sugar in the syrup and the sugar entering the factory indicates the loss in the scums plus the undetermined loss. On applying this method of calculation in factories in Mauritius, it was found that the loss in the scums plus undetermined loss may vary between from 0.60 to 0.10, and even less, on the weight of cane crushed.—J. P. O.

Melezitose; Occurrence of — in a manna from the Douglas fir. C. S. Hudson and S. F. Sherwood. J. Amer. Chem. Soc., 1918, 40, 1456–1460.

A SAMPLE of manna from the Douglas fir yielded about 50% of pure, crystallised melezitose, and there is evidence that it contained sucrose and some reducing sugar, probably a mixture of dextrose with a smaller quantity of levulose. The percentage composition of the sample of dried manna was approximately: melezitose, 75–83; sucrose, 2.9; reducing sugars, 11.5%. At present, the only other known natural source of melezitose in any quantity is the Turkestan manna (Tarandjabiné), which is, however, considerably inferior to the Douglas fir product in point of yield.—H. W.

l-Glucosan; Conversion of — into dextrin. A. Pictet. Helv. Chim. Acta, 1918, 1, 226–230.

WHEN kept at 240° C. for 30–60 minutes or, better, at 180° C. for a few minutes in the presence of platinum black as catalyst, *l*-glucosan (see this J., 1918, 49A) is converted into a white amorphous powder, $(C_6H_{10}O_5)_n$, $[\alpha]_D$ varying from +111.9° to +106.5° in different preparations, which exhibits the characteristic properties of a dextrin and yields dextrose when warmed with dilute sulphuric acid.—C. S.

PATENT.

Starch; Process for producing laundry —. S. B. Chambers, Chicago, Ill. U.S. Pat. 1,276,722, 27.8.18. Appl., 1.12.16.

DRY maize starch, 100 lb., is mixed with 15 oz. of powdered borax and treated with a solution of 6 oz.

of nitric acid in 6 galls. of water; the mixture is allowed to remain for 24–48 hours, during which time it is stirred at intervals to prevent excessive heating, and is finally dried at 130°–155° F. (54.5°–68.5° C.).—J. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Alcoholic fermentation; Role of the phosphate in —. H. Euler and S. McIntze. *Z. physiol. Chem.*, 1918, 102, 252–261.

THE extent of the esterification of phosphoric acid which occurs when dried yeast is incubated with dextrose in the presence of disodium hydrogen phosphate and a protoplasmic poison, such as phenol, is dependent on the amount of water remaining in the yeast after the drying process. The maximum esterification was observed when dried yeasts containing from 10 to 15% of moisture were employed. Increasing the quantity of yeast used in the individual experiments appeared to cause a relatively much greater increase in the amount of hexose-phosphate produced.—H. W. B.

Fermentation [by zymase]; Kinetics of the cell-free —. O. Meyerhof. *Z. physiol. Chem.*, 1918, 102, 185–225.

THE interval which elapses between the addition of sugar to an extract of dried yeast and the appearance of fermentation (the "induction period") can be shortened by previously warming the sugar solution with disodium hydrogen phosphate or by grinding the dried yeast with glass powder. This shortening of the induction period is probably due to the formation or liberation of hexose-phosphate, the addition of a small quantity of which suffices to cause the immediate onset of fermentation with evolution of carbon dioxide. The rate of fermentation is dependent on the amount of free phosphate present; by increasing the latter, the rate at which the velocity of fermentation increases is reduced, but the maximum velocity eventually attained is higher than in the absence of free phosphate until a certain maximum amount of phosphate is reached; further addition of the phosphate then reduces the maximum velocity of fermentation attainable. The addition of other salts such as sodium chloride produces similar effects on the velocity of fermentation; the free phosphate functions therefore as a salt as well as exerts its specific zymase-activating action. Fermentation is accelerated by the addition of hexose-phosphate or of ferment such as is present in boiled yeast extract.—H. W. B.

Wood-waste as a source of ethyl alcohol. G. H. Tomlinson. *Chem. and Met. Eng.*, 1918, 19, 552–568.

THE past failures in the attempts to utilise sawdust and other forms of wood-waste as a source of alcohol are due to premature development of the process under unsuitable commercial conditions. It is not necessary for the fermentation part of the process to be carried out at the same time as the conversion; the solution of soluble carbohydrates obtained from the wood may be evaporated to a syrup resembling cane molasses and transported for fermentation elsewhere. The residue from the wood-waste (about 70%) is not depreciated in value as fuel, and the important factor in the development of the industry is the cost of the syrup compared with that of cane molasses. The cost of the plant used by the Standard Alcohol Co. at Fullerton, La., was \$456,920, of which about \$200,000 represented the

cost of the plant and equipment for the conversion of the wood into sugar and the separation of this in the form of a solution, and the balance for the fermentation and distillation plant. Working for 22 days in 1913 at three-quarter capacity, this plant dealt with 6125 tons of green waste wood containing 48% of moisture, and yielded 1,688,600 galls. of sugar solution of about 10.3% strength, at a total cost, including allowance for depreciation of plant, of 31.8 cents per 100 galls. The molasses obtained by concentrating 100 galls. of the sugar solution to 12½ galls. may be taken as costing about 3 cents per gall. including evaporation. On the other hand, whilst a gallon of wood molasses would yield only about 0.39 gall. of proof spirit, cane molasses yields about 1 gall. of spirit. In practice, although about 24% of the dry wood was rendered soluble, only about 8.5% was converted into fermentable sugars, but by proper chemical control of the operations the author considers that it should be possible to obtain a product equal to cane molasses in fermentable value.—C. A. M.

Ethyl and methyl alcohols; Method of determining the amount of methyl alcohol in mixtures of —. W. G. Toplis. *Amer. J. Pharm.*, 1918, 90, 636–640.

THE method depends on the measurement of the volume of hydrogen liberated on treating the dried alcohol with sodium. The sample is compared with a standard sample of denatured alcohol of known composition. The apparatus consists of a small test-tube weighted so as to sink in petroleum spirit contained in a hydrometer jar. The test-tube carries a gas-leading tube of brass terminating in a trap which allows the hydrogen to pass out but prevents the entrance of the liquid. Six drops of the alcohol is placed in the test-tube and a piece of sodium carried on the point of a needle which is suspended by a thread which passes up through the gas outlet. An inverted burette filled with petroleum spirit is placed over the test-tube submerged in the hydrometer jar and releases the suspended needle. The reaction begins at once and the hydrogen is collected in the burette. If two operations are conducted side by side, the sample may be compared with the standard without correcting the volume of gas evolved. If the reading of the unknown sample is less than that of the standard, it is deficient in wood spirit. The alcohols must be dehydrated before making the test by treatment with fused potassium carbonate.

—J. F. B.

PATENTS.

Alcohol-reduced beverages; Apparatus for making —. H. Heuser, Chicago, Ill. U.S. Pat. 1,277,931, 3.9.18. Appl., 25.11.16.

A VERTICAL vacuum evaporator surrounded by a steam jacket at the sides and the bottom is supplied with a vapour outlet at the top, a liquid outlet at the bottom, and a liquid sprayer arranged to discharge a film of liquid on to the heated sides, thereby momentarily boiling the beverage in the form of a flowing film. Steam is supplied to the jacket by a bank of separately controlled pressure steam injectors.—L. A. C.

Alcohol; Process for producing —. B. Kazmann, Battle Creek, Mich., U.S.A. Eng. Pat. 119,333, 15.11.17. (Appl. 16,829/17.)

SEE U.S. Pat. 1,267,681 of 1918; this J., 1918, 558 A.

Solidified alcohol. U.S. Pat. 1,277,149. See II A.

XIXA.—FOODS.

Milk; New formula for the calculation of added water in —. L. J. Harris. *Analyst*, 1918, **43**, 345–347.

A FORMULA is given by means of which the percentage of added water is calculated on the assumption that the original milk, before the addition of water, contained the official minima of fat and solids-not-fat (3.0 and 8.5%, respectively); allowance is made for any excess or deficiency of fat. Let N and F be the percentages of solids-not-fat and of fat in the milk-water mixture, and x the percentage of milk of minimum fat and solids-not-fat content in the mixture, then the solids-not-fat should be $8.5 \frac{x}{100}$, the fat $3 \frac{x}{100}$, and the water $100 - 11.5 \frac{x}{100}$. Now the rising of cream has resulted in the fat content changing from $3 \frac{x}{100}$ to F , and the remaining total constituents (water + solids-not-fat) will have changed from $100 - \frac{3x}{100}$ to $100 - F$, and there will now be

$$\frac{100 - F}{100 - 3 \frac{x}{100}} \times \left(100 - 11.5 \frac{x}{100} \right) \% \text{ of water.}$$

$$\text{and } \frac{100 - F}{100 - 3 \frac{x}{100}} \times 8.5 \frac{x}{100} \% \text{ of solids-not-fat.}$$

$$\text{Hence } N = \frac{8.5x(100 - F)}{10,000 - 3x},$$

$$\text{and } x = \frac{10,000 N}{3N + 8.5(100 - F)}.$$

The percentage of added water in the milk will be $100 - x$.—W. P. S.

Pastry; Detection of milk in —. J. Grossfeld. *Z. Unters. Nahr. Genussm.*, 1918, **35**, 457–471.

THE method proposed depends on the conversion of lactose into mucic acid. Fifty grms. of the sample is shaken with 500 c.c. of water, filtered, and 250 c.c. of the filtrate evaporated to a thin syrup with the addition of 5 c.c. of glacial acetic acid; the syrup is treated with 100 c.c. of warm 90% alcohol, the mixture filtered, and the filtrate evaporated to dryness. If a large quantity of sucrose is also present, this dry residue must be dissolved in 100 c.c. of alcohol, 100 c.c. of ether added, the precipitated sugars collected after 24 hours, and again treated with alcohol and ether. In this way the lactose is concentrated in the precipitate and the greater part of the other sugars removed. The precipitated lactose is heated for a short time on a water-bath with 30 c.c. of nitric acid (sp. gr. 1.15), the solution filtered, and the filtrate placed aside; mucic acid usually crystallises out within 24 hours, but may require several days. The mucic acid obtained melts at 200° – 210° C., and each grm. requires 9.5 c.c. of $N/1$ sodium hydroxide for neutralisation. About 30% of the lactose present is converted into mucic acid. The calcium oxide content of pastry may also afford some indication as to whether milk has been used in its preparation; pastry made without milk may contain up to 0.2% of calcium oxide (calculated on the dry substance); the presence of milk increases this quantity, but, especially if the calcium oxide content exceeds 0.35%, the increase may be due to ingredients other than milk.—W. P. S.

Fat-soluble vitamine [of butter-fat]. I. H. Steenbock, P. W. Boutwell, and H. E. Kent. *J. Biol. Chem.*, 1918, **35**, 517–526.

THE fat-soluble vitamine in butter-fat is destroyed by heating the butter-fat at 100° C. for 4 hours.
—H. W. B.

Starch; Brake-fern (Pteris aquilina, L.) as a source of —. A. Zlataroff. *Z. Unters. Nahr. Genussm.*, 1918, **35**, 483–484.

ELEVEN kilos. of washed and dried brake-fern roots yielded 7.6 kilos. of meal which contained:—water, 8.04; starch, 46.00; cell tissue, 22.11; ash, 10.48%. The meal had a grey colour and a bitter taste, but the latter might be removed by washing and sedimentation; it appears to be more suitable as a cattle food than for bread-making.—W. P. S.

Cottonseed products; Comparative toxicity of —. W. A. Withers and F. E. Carruth. *J. Agric. Res.*, 1918, **14**, 425–452.

FEEDING experiments on rats, rabbits, poultry, and pigs were made with cottonseed meal, raw cottonseed kernels, ether-extracted kernels, and gossypol. Toxic properties were found in all the products. If the meal had been prepared by the "cold-pressing" process, most of the toxic properties passed into the oil. Cooking of the products under oil-mill conditions caused them to become non-toxic to rabbits and pigs. This was due to the oxidation of the gossypol to its derivative "D-gossypol," which was far less toxic. (See also this J., 1917, 562, 937, 1061, 1285; 1918, 164 A, 319 A.)—J. H. J.

Coffee; Determination of caffein in —. E. Vautier. *Ann. Chim. Analyt.*, 1918, **23**, 207–210.

FIVE grms. of the finely powdered sample is moistened in an extraction thimble with 5 c.c. of ammonia and then extracted in a Soxhlet apparatus for 4 hrs. with ether; the extract is evaporated, the residue treated with boiling water, the solution filtered, and the insoluble portion washed with boiling water until 150 c.c. has been collected. The filtrate is evaporated, the residue dissolved in a small quantity of boiling water, the solution filtered, the insoluble portion washed, and the filtrate again evaporated in a small basin. The residue thus obtained is heated and the sublimed caffeine collected on a watch-glass and weighed.—W. P. S.

Silage made from various crops; Acidity of —. R. E. Neidig. *J. Agric. Res.*, 1918, **14**, 395–409.

EXPERIMENTS were made to determine whether other crops than maize could be used for the production of silage. It was found that oats, peas, clover, and mixtures of oats with peas, wheat with peas, and clover with wheat straw made excellent silage, and produced acetic, propionic, and lactic acids in similar amounts to maize silage. Alfalfa (lucerne) made poor silage, and produced butyric acid only.

Erratum.

THIS J., Nov. 15, 1918, p. 667 A, col. 2, line 6 from bottom should read "constituents of milk caused by bacteria before any".

PATENTS.

Milk and similar liquids; Process for sterilising — F. G. Leconite, Amsterdam. Eng. Pat. 116,490, 20.7.17. (Appl. 10,455/17.) Int. Conv. 7.6.17.

MILK, condensed or raw, is placed in a closed vessel, and air at a pressure of 1.2 atmospheres is forced into the liquid for about 30 minutes, so that some air is dissolved. The milk is then sterilised at 105°–110° C.—W. F. F.

Lacteal fluids; Method of treating — [Manufacture of butter.] E. B. Heller, Assignor to The Vacuum Churn Corporation, New York. U.S. Pat. 1,276,910, 27.8.18. Appl. 19.1.15. Renewed 19.6.16.

MILK is pasteurised, churned, and worked in a rotating partially exhausted vessel, having smooth, non-porous, non-absorbent walls, which are cooled below 62° F. (17° C.), with the object of preventing adherence of the globules of butter formed in the process.—C. A. M.

Edible oils and fats; Means for imparting a definite flavour to — De Bruyn, Ltd., and J. De Bruyn, London. Eng. Pat. 119,052, 21.6.17. (Appl. 8029/17.)

CRUDE proteins are extracted from vegetable matter such as the seeds or fruits of leguminous plants, the extract is inoculated at about 70° F. (21° C.) with an active culture of lactic bacteria, and after attaining the required degree of sourness it is emulsified with edible oils and fats at a suitable temperature (70° to 100° F., 21°–38° C.). The extract of crude proteins may be evaporated and the residue dried to obtain a dry product which may be kept for subsequent dilution with water and ripening with lactic bacteria. By this means a butter-like flavour is imparted to edible oils and fats more economically and with greater uniformity than by the use of cows' milk.—C. A. M.

Fruit-dryer. U. G. Stover, Waynesboro', Pa. U.S. Pat. 1,276,988, 27.8.18. Appl. 15.10.17.

FRUIT is dried in a frame, with open upper and lower ends, which contains a series of removable superposed trays. Attached by hinges to opposite sides of the top of the frame are two plates, having openings in their margins near the hinges, and adapted to be brought together over the top of the frame, or fixed at different positions in relation thereto.—C. A. M.

Food product. P. R. Welch, Assignor to The Welch Grape Juice Co., Westfield, N.Y. U.S. Pat. 1,277,672, 3.9.18. Appl. 4.10.17.

A MIXTURE of grape pulp and juice is stored until argol crystallises throughout the mass. The argol is separated, and the pulp and juice are mixed with sugar and cooked until the proper consistency is reached.—J. H. P.

Eggs; Process of recovering substances from fresh, decomposed, or partially decomposed — J. M. Hussey, Wichita, Kans. U.S. Pat. 1,277,727, 3.9.18. Appl. 29.12.16.

SUFFICIENT salt is added to fresh, decomposed, or partially decomposed eggs to form a brine, thus dissolving the vitellin, and carbon tetrachloride and methyl alcohol are then added in sufficient quantities to dissolve the oils and fats and to precipitate the albumin. The solution of oils and fats, which also contains lecithin, is drawn off, the fat-solvent (carbon tetrachloride) recovered, and the lecithin

precipitated from the mixture of oils and fats by the addition of sufficient fat-solvent and acetone. The lecithin is then strained out and the fat-solvent and acetone recovered from the solution. After straining off the albumin, methyl alcohol is separated from the solution containing the vitellin by distillation, and the vitellin obtained by the addition of sufficient water to dissolve out the salt, leaving the vitellin as a precipitate.—L. A. C.

Flour and starch from potatoes and other tubers and roots and other materials; Machinery for use in production of — R. G. McLeod, London. Eng. Pat. 119,531, 4.10.17. (Appl. 14,319/17.)

Milk; Process of making a new food product of — P. W. Turney, Richmond, Va., U.S.A. Eng. Pat. 119,430, 24.6.18. (Appl. 10,414/18.)

SEE U.S. Pat. 1,274,218 of 1918; this J., 1918, 669 A.

XIXB.—WATER PURIFICATION; SANITATION.

Waters; Hypochlorites in drinking — A. R. Ling. Analyst, 1918, 43, 347–348.

TREATMENT of drinking water with hypochlorite converts the ammonia and amino compounds present into chloramine and chloramino derivatives, and does not reduce the ammonia and albuminoid ammonia content as determined by the Nessler method. The fact that the chlorine in chloramines liberates iodine from potassium iodide may be used to ascertain whether a water containing much nitrogenous matter has been treated with hypochlorite. Fifty c.c. of the water and 50 c.c. of distilled water are placed in two cylinders and each treated with 1 c.c. of N/1 sulphuric acid and 0.1 gm. of potassium iodide. If the water has been treated with hypochlorite a brown coloration develops, whilst the distilled water will remain colourless. Nitrites, which also liberate iodine from potassium iodide, would have been oxidised by the hypochlorite.

—W. P. S.

Water purification; Baryta as substitute for soda in — F. Hundeshagen. Z. öffentl. Chem., 1918, 24, 175–186.

SEE this J., 1918, 670 A. The author gives examples of the cost of treatment by the baryta process for various combinations of hardening salts, as well as directions for the chemical control of the process in practice.—J. H. J.

Disinfection by alcohol; Theory and practice of — J. Christiansen. Z. physiol. Chem., 1918, 102, 275–305.

THE disinfecting power of alcohol cannot be associated entirely with its property of precipitating the proteins of bacteria, because those concentrations of various alcohols which cause the same amount of precipitation of a protein differ greatly in their disinfecting efficiency. One of the most important factors in disinfection is the capacity of the disinfectant to penetrate the cell-walls of the bacteria, and this is largely determined by the surface tension of the disinfectant. Of all the alcohols, propyl alcohol appears to possess the most valuable qualities required by a disinfectant for direct application to the epidermis prior to surgical operations. Its solutions have lower surface tensions than solutions of corresponding concentrations of ethyl alcohol, which has hitherto been largely employed in this

connection. Moreover, the toxicity of propyl alcohol is at least four times as great as that of ethyl alcohol, and, owing to its greater solvent power for fats, it is able to enter readily the pores of the skin.—H. W. B.

Sodium hypochlorite solutions; Hydrogen ion concentration of various indicator end-points in dilute —. G. E. Cullen and J. H. Austin. *J. Biol. Chem.*, 1918, 34, 553–568.

In the preparation of his hypochlorite solution for wound disinfection (this J., 1915, 919), Dakin added boric acid to a strongly alkaline hypochlorite solution until it no longer coloured powdered phenolphthalein. It is pointed out by the authors that such a solution is still alkaline; in consequence of the bleaching action of the hypochlorite, a much greater alkalinity is required to give a colour with phenolphthalein when hypochlorite is present than in its absence. Experiments showed that in a 0.5% solution of sodium hypochlorite, in which all the hypochlorite is present as NaClO, the end-point to powdered phenolphthalein is at p_{H} = about 10.1, and to an alcoholic solution of *o*-cresolphthalein (this J., 1916, 980) about 9.3. With an alcoholic solution of phenolphthalein as indicator, the end-point is uncertain owing to rapid decomposition of the hypochlorous acid which forms a considerable proportion of the total hypochlorite in dilute solutions of hypochlorite. With a 1% solution of sodium hypochlorite, in which 7–17% of the total hypochlorite is present as HClO, the end-point to an alcoholic solution of *o*-cresolphthalein is at p_{H} = about 9.6. Such a solution is sufficiently stable to be satisfactory for clinical use, and might perhaps be tolerated upon skin and other tissue surfaces which would not bear the more alkaline solution prepared as described by Dakin. It can be readily prepared by passing chlorine gas through a solution of sodium carbonate, of an initial concentration of 14 grms. per litre, till the concentration of sodium hypochlorite, as shown by titration with thio-sulphate, is 0.5%; the resulting solution has p_{H} = about 9.4.

Phenols as preservatives of anti-pneumococcic serum. C. Voegtlin. U.S. Pub. Health Service, Hyg. Lab., Bull. No. 112, 1918, 5–13.

It is usual to preserve anti-pneumococcic serum by the addition of 0.3–0.5% of phenol or cresol. As large amounts of the serum are used in injections, an investigation was made by experiments on animals to determine whether the amount of phenols thus injected was injurious. No toxic effects were observed in the animals experimented on.—J. H. J.

Biological products; Studies in preservatives of —. *Effects of certain substances on organisms found in biological products.* M. H. Neill. U.S. Pub. Health Service, Hyg. Lab., Bull. No. 112, 1918, 37–46.

It is usual to add 0.5% of phenols to biological products, such as vaccines, serums, etc., to keep them sterile, but occasionally living organisms are found to be present in them. Cultures of some of these organisms, mainly cocci, were exposed to the action of dilutions of phenol, 1 in 110, and of formaldehyde, 1 in 50, and these substances were found to be ineffective as germicides. The use of stronger solutions would be deleterious to the biological product and unduly toxic.—J. H. J.

Ether; Effect of — *on tetanus spores and on certain other micro-organisms.* H. B. Corbitt. U.S. Pub. Health Service, Hyg. Lab., Bull. No. 112, 1918, 47–48.

ETHER was found to be ineffective for destroying spores of the tetanus bacillus even after two weeks' treatment, whereas cultures of *Staph. aureus* and *B. typhosus* were easily killed.—J. H. J.

Nitrites and nitrates. Oelsner. See VII.

PATENTS.

Evaporating and distilling machinery [for seawater]. D. Urquhart, London. Eng. Pat. 119,106, 2.10.17. (Appl. 14,217/17.)

To obtain distilled water on board ships which are propelled by internal combustion engines, salt water is evaporated and distilled by means of steam produced by heating distilled water in tubular heaters or boilers by means of the exhaust gases from the engines. The heaters may be of the water-tube or fire-tube type.—W. H. C.

Water-purification system; Vacuum — *[for removal of gaseous impurities].* O. M. Campbell, Kansas City, Kans. U.S. Pat. 1,276,871, 27.8.18. Appl. 27.1.16.

WATER is purified by distillation and gaseous impurities are removed by subjecting the vapour during condensation to a "continuous vacuum action" at various points corresponding to the various stages of condensation of the vapour.

—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Nux vomica and its preparations; Variations in —. H. H. Schaefer. Amer. J. Pharm., 1918, 90, 633–635.

The specification for *Nux vomica* in the U.S. Pharmacopœia VIII required 1.25% of strychnine after the removal of the brucine with nitric acid. This has been revised in the U.S.P. IX, which specifies 2.5% of total alkaloids without regard to the proportions of strychnine and brucine. The author has analysed several samples of powdered *Nux vomica* and its fluid extract and tincture and found considerable variations; the percentage of strychnine in the total alkaloid ranged from 33 to 53. Hence certain samples may pass the new total alkaloid specification which would not pass the old strychnine specification. One sample of *Nux vomica* contained 2.52% of total alkaloids but only 0.73% of strychnine, and another contained 1.26% of strychnine but only 2.38% of total alkaloids. The author considers that there would be no difficulty in meeting a specification which comprised both requirements, viz. at least 2.5% of total alkaloids and 1.25% of strychnine.—J. F. B.

Biological products; Nature of contaminations of —. I. A. Bengtson. U.S. Pub. Health Service, Hyg. Lab., Bull. No. 112, 1918, 14–36.

VARIOUS biological products, such as vaccines, anti-toxins, and tuberculins, were examined for their freedom from bacterial contamination. Occasionally organisms were found to be present, mainly staphylococci, streptococci, and bacilli. Spore-bearing bacilli were most frequently found, usually in bacterial vaccines and in tuberculins. The next most frequent were staphylococci, usually found in

small-pox and rabies vaccines. Other organisms found were streptococci, bacilli, and one anaerobic bacillus. The organisms were mainly saprophytic, though in a few cases pathogenic species were isolated from small-pox and rabies vaccines and tetanus antitoxin.—J. H. J.

Piperazine; Preparation of —. D. S. Pratt and C. O. Young. J. Amer. Chem. Soc., 1918, 40, 1428–1431.

The following process has proved satisfactory. A mixture of ethylene bromide, aniline, and anhydrous sodium carbonate is heated to gentle boiling for 5–6 hours; the warm melt is extracted with hot water, and the crude diphenylpiperazine is transformed into its nitroso-derivative by suspending it in cold, concentrated hydrochloric acid and gradually adding a saturated solution of sodium nitrite through a tube reaching to the bottom of the acid. The precipitate, probably the hydrochloride of dinitrosodiphenylpiperazine, is added to a 40% solution of sodium bisulphite and the suspension warmed to about 80° C.; the solution is made strongly alkaline with sodium hydroxide, and concentrated by distillation. The piperazine is finally isolated by distillation of the residue with superheated steam and is absorbed by hydrochloric acid. Traces of piperazine are conveniently detected by means of platonic chloride, picric acid, or bismuth potassium iodide (brilliant garnet crystals) or by the formation of dinitrosopiperazine.—H. W.

Picramic acid; Modified method for the preparation of —. G. Egerer. J. Biol. Chem., 1918, 35, 555–566.

Picric acid is dissolved in alcohol, treated with ammonia, and reduced by hydrogen sulphide, first at 50° C. and then at 0° C. The ammonium picramate is deposited in crystalline form and the free acid is subsequently liberated by treatment with acetic acid, and purified by recrystallisation from boiling water. The yield is 75 to 80% of the theoretical quantity. (See further J. Chem. Soc., 1918, i., 496.)—H. W. B.

Benzaldehyde and benzoic acid; Use of benzaldehyde sulphite compound as a standard in the quantitative separation and estimation of —. G. A. Geiger. J. Amer. Chem. Soc., 1918, 40, 1453–1456.

BENZALDEHYDE is unsuitable as a standard as it is too readily oxidised, but the bisulphite compound, $C_6H_5CHO \cdot NaHSO_3 \cdot 2H_2O$, fulfils the required conditions. The estimation is carried out as follows: Solutions containing as a maximum 0.5 gram. of benzoic acid and benzaldehyde are made distinctly alkaline with sodium hydroxide and extracted with three portions of ether (each 25 c.c.); the combined ethereal extracts are treated with freshly distilled phenylhydrazine (1.5 grms.) and 10 c.c. of a 10% solution of acetic acid in ether. The solution is evaporated in a current of air; the residue is mixed with water (50 c.c.), and the insoluble benzylidene-phenylhydrazine is collected in a tared Gooch crucible, dried for 2 hours at 70° C. in a vacuum, and weighed. The solution from which the benzaldehyde has been extracted is rendered slightly acid with hydrochloric acid (1:3), extracted with chloroform (25 c.c.), saturated with salt, and shaken three times with chloroform (25 c.c. for each operation). The chloroform is evaporated at the ordinary temperature and the residue is dissolved in neutral 50% alcohol and titrated with sodium hydroxide. If the ethereal solution of benzaldehyde is washed with 25 c.c. of N/5 sodium hydroxide, the quantity of benzoic acid separated is larger, and the accuracy of the method is increased.—H. W.

Benzoylation of some hydroxyl or amino aromatic compounds. F. Reverdin. Helv. Chim. Acta, 1918, 1, 205–209.

A MIXTURE of the substance and benzoyl chloride is treated with two or three drops of concentrated sulphuric acid and, if necessary, warmed for a short time on the water-bath. The method is successful with substances which are unaffected by the usual methods of benzoylation. (See also J. Chem. Soc., Dec., 1918.)—C. S.

Nucleic acids; Determination of the purine bases in — after cleavage without the production of humin. R. Feulgen. Z. physiol. Chem., 1918, 102, 244–251.

THE nucleic acid is hydrolysed by heating with sodium bisulphite at 160° C. under pressure. On cooling, guanine separates quantitatively from the colourless, humin-free solution, whilst the adenine is estimated in the filtrate by conversion first into the phosphorungstate, then into the silver salt, and finally into the picrate, which is dried and weighed.—H. W. B.

Histidine and other glyoxaline derivatives; Volumetric estimation of —. C. L. Lautenschläger. Z. physiol. Chem., 1918, 102, 226–243.

THREE methods are described for the estimation of histidine: (a) by direct titration with a standard silver nitrate solution until a red coloration is no longer observed when a drop is mixed with a drop of an alkaline solution of diazobenzenesulphonic acid, (b) by direct titration with diazobenzenesulphonic acid, using, as an indicator, technical "K" salt (which gives a darker-coloured dye with the diazo-acid than histidine), (c) by adding an excess of the diazo-acid, boiling with alcohol to destroy the excess of acid, and then titrating the stable histidine dye with titanium trichloride. The histidine must in all cases be first separated from other substances, such as tyrosine, which react with diazobenzenesulphonic acid, before the titration is carried out. Methods (a) and (c) yield more accurate results than (b).—H. W. B.

Vitamins; Pharmacology of the —. H. F. Uhlmann. Z. Biol., 1918, 63, 457–498.

THE close parallelism between the effects on animal tissues produced by pilocarpine and by vitamin preparations from various sources (oryzan, extracts of oats, nettles, blood, etc.) confirms the author's previous conclusion, viz., that the antineuritic vitamin is a substance physiologically closely related to pilocarpine, which acts on the sympathetic nerve endings and thus exerts a controlling influence on the tones of the muscles in the organism.—H. W. B.

Formic, acetic, and lactic acids; Separation of —. I. Onodera. Ber. Ohara Inst. landw. Forsch., 1917, 1, 231–259.

THE solution containing the three acids is extracted with ether for 4 hrs. in a modified Soxhlet apparatus, the extraction flask containing an excess of N/10 sodium hydroxide solution. The excess of alkali is then neutralised with N/10 phosphoric acid solution (this gives a measure of the total acidity), an excess of phosphoric acid is added, and the mixture steam-distilled at 140°–160° C. for 2 hrs. or until the distillate no longer shows an acid reaction; the distillate is collected in an excess of alkali solution, the latter neutralised with sulphuric acid, and diluted to a definite volume. To determine the formic and lactic acids an aliquot portion of this solution is treated with 1.5 grms. of sodium carbonate and an excess of N/10 permanganate

solution, diluted to 100 c.c., and heated at 100° C. for 35 mins., and the excess of permanganate determined iodometrically. Another portion of the solution is then heated for 1 hour at 100° C. with the addition of 1.5 grms. of sodium carbonate and excess of 3.2% permanganate solution, the excess of the latter is destroyed with hydrogen peroxide, the mixture filtered, the filtrate evaporated, and the oxalic acid formed by the oxidation of the lactic acid is precipitated as calcium oxalate and this is titrated in the usual way with permanganate solution. Each c.c. of N/50 permanganate solution is equivalent to 0.0009 gm. of lactic acid; the formic acid is found by difference. Acetic acid is determined by oxidising a third portion of the solution as described, decomposing the excess of permanganate with hydrogen peroxide, evaporating the filtered liquid, acidifying the residual liquid with sulphuric acid, and extracting it with ether, the extraction flask in this case containing a small quantity of water. A portion of the extract is then diluted to 100 c.c. and distilled, 95 c.c. of distillate being collected and titrated. Under these conditions 84.49% of the acetic acid is found in the distillate.—W. P. S.

Glycols; Manufacture of — [and explosives therefrom]. H. Hibbert. Chem. and Met. Eng., 1918, 19, 571—573.

APART from its preparation from alcohol, ethylene-glycol may be obtained in a less pure condition by cracking petroleum vapours in an iron tube at about 650° C., mixing the resulting gases with chlorine, purifying the product by distillation, and treating the distillates with alkali carbonates in a closed vessel. The mixture of glycols thus obtained consists of liquids somewhat less viscous than glycerin, but having even more pronounced hygroscopic properties. When nitrated the glycols yield products which freeze at much lower temperatures than nitroglycerin, and, unlike the latter, do not form an unstable crystalline modification at a low temperature. Hence they are much less dangerous to handle, and should prove of especial value for mining and blasting operations at low temperatures. Experiments on a manufacturing scale have shown that when these products are compounded with nitro-cellulose (for which process no solvent is necessary) a new type of explosive is obtained, which causes much less erosion of gun-barrels than cordite. A solution of sugar in glycol yields, when nitrated, another new type of explosive, which has valuable properties for such purposes as blasting, excavating, etc. The use of glycol is suggested as a substitute for glycerin for moistening tobacco, with the object of obviating the formation of acrolein during smoking. Owing to its pronounced hygroscopic properties it should also be a valuable constituent of ointments and other pharmaceutical preparations, and would probably be an efficient substitute for alcohol as a means of preventing the freezing of water in motor radiators. (See also J. Chem. Soc., Dec., 1918.) —C. A. M.

Methylamine; Preparation of — H. I. Jones and R. Wheatley. J. Amer. Chem. Soc., 1918, 40, 1411—1415.

THE results recently published by Werner (this J., 1917, 1147) have led the authors to describe experiments made with the object of studying the effect of reduced pressure on organic reactions in which a gas is evolved. Mixtures of ammonium chloride and formaldehyde were (1) slowly distilled at the ordinary pressure, (2) slowly distilled in a vacuum, (3) heated under a reflux condenser for 8 hours and then distilled at the ordinary pressure, and (4) heated under a reflux condenser for 4½ hours in

a vacuum and then distilled in a vacuum. In method (4) there was a decrease in the amount of ammonium chloride left unchanged, a lowering of the temperature and therefore decrease of the yield of dimethylamine and higher methylated substances, and an increase in the acidity of the distillate, the loss of carbon dioxide, and the weight of methylamine produced. Method (2), merely by removing the volatile products as well as the carbon dioxide, caused a marked increase in the weight of the distillate and the amount of ammonium chloride remaining unchanged; it caused the formation of the lowest percentage of dimethylamine but also lowered markedly the amount of monomethylamine formed, brought about a higher percentage of esterification, and gave a distillate of the highest rotatory power. Method (3) gave the smallest percentage of distillate, the highest percentage of non-distillable residue, the highest percentage of esterification, used up a large amount of ammonium chloride, and gave the highest degree of methylation, and consequently the highest percentage of dimethyl and other more highly methylated derivatives, most of which will not crystallise. The theory of the reaction advanced by Werner (*loc. cit.*) is correct and explains all the observed facts. Monomethylamine is best prepared by method (4). —H. W.

Allyl group in essential oils; Kobert's phloroglucinol-hydrochloric acid reaction for the detection of — S. Furukawa. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 513—515.

THE red coloration which certain aromatic compounds give with phloroglucinol and hydrochloric acid is not, as claimed by Kobert, invariably a trustworthy test for the presence of the allyl group in essential oils. In the case of eugenol or safrol, for instance, the characteristic coloration is not obtained until the oils have been kept for at least 6 months at the ordinary temperature. On fractional distillation of such oils under reduced pressure, the first fraction does not give the reaction until after it has been kept for a long time. Moreover, certain compounds of the fatty series, such as citronellol and geraniol, give a red-brown coloration with phloroglucinol and hydrochloric acid, whilst others, such as citronellal and citronellic acid, do not give any coloration.—C. A. M.

Citronella oils S. Furukawa. Kōgyō-Kwagaku-Zasshi (J. Chem. Ind., Tokyo), 1918, 21, 515—525.

A SAMPLE of citronella oil from Formosa had the following characters:—Sp. gr., 0.9601; total geraniol, 22.15%; and total citronellal, 11.05%. Formosa oil is thus of less value for perfumery than Java or Ceylon citronella oil. The composition of Formosa oil somewhat resembles that of the oil of "ogarugaya," a variety of *Andropogon nardus*, L., growing in Japan. A Java oil was found to contain two phenols (eugenol and possibly chavicol), and three acids, one of which was identified as citronellic acid.—C. A. M.

PATENTS.

Alcohols; Process of producing —. E. C. R. Marks, London. From E. I. du Pont de Nemours and Co., Wilmington, Del., U.S.A. Eng. Pat. 119,249, 9.6.17. (Appl. 8259/17.)

A HALOGENATED hydrocarbon, e.g. pentyl or hexyl chloride, is treated with a salt of a non-corrosive fatty acid of high boiling point, e.g. sodium stearate, to form the ester of an alcohol, which is subsequently recovered by hydrolysing the ester. Stearic acid and solid caustic soda are heated in a jacketed vessel at 200°–240° C. and when the water has been expelled, a mixture of pentyl and hexyl chlorides is introduced at the bottom of the vessel. A portion of the halogenated hydrocarbon reacts with the sodium stearate, another portion is converted into olefines, and part distils unchanged. The volatile products are condensed and separated, for which purpose a reflux cooler maintained at a suitable temperature to return the volatile chlorides to the vessel may be provided. The stearic ester in the vessel is cooled to about 150° C., treated with sufficient caustic soda to replace that which has reacted with the chlorides, heated again to 200°–240° C. and the resulting alcohol is distilled off in the presence of a little water or steam.—J. F. B.

Dimethyl sulphate; Process for the production of —. E. J. Boake, London, and T. H. Durrans, Oxford. Eng. Pat. 119,250, 20.6.17. (Appl. 8862/17.)

METHYL alcohol (2 mols.) is treated with sulphur dioxide and chlorine (approximately 1 mol. of each), the sulphur dioxide being preferably in slight excess. The gases may be passed either simultaneously or successively; in the former case the necessary excess of sulphur dioxide may be added at the start. Methyl chloride is a gaseous product of the reaction. The dimethyl sulphate is isolated and purified by distillation under reduced pressure; the yield is nearly equal to the theoretical quantity.—J. F. B.

Secale cornutum [ergot]; Preparation from —. O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 119,287, 27.9.17. (Appl. 13,964/17.)

ERGOT (*Secale cornutum*) after treatment for removal of oil, e.g. with petroleum ether, is extracted with cold water and then with alcohol of about 80% strength containing about 0.1% of a volatile acid, such as formic or acetic acid. After removal of the alcohol and excess acid from the alcoholic extract by distillation *in vacuo*, water being added during the distillation, the extracts are mixed and further concentrated to a liquid of definite strength or to a yellowish-brown hygroscopic powder. Inorganic constituents are removed by treatment with alcohol. The product is soluble in water and suitable for injection.—B. V. S.

Substances which arrest and cause coagulation of the blood; Separation of — from animal organs. Luftpold-Werk, Chem.-pharm. Fabr., Munich. Ger. Pat. 306,805, 14.7.16.

A SUBSTANCE which causes coagulation of the blood is prepared by extracting finely divided animal organs with an alkaline aqueous solution and then treating the solution with an acid in the presence of phenol or with salicylic acid; on the other hand, if the organs (or the residue after treatment with alkali) are extracted with dilute acid and the solution neutralised, a substance is obtained which arrests blood coagulation.—L. A. C.

Ovaries, corpus luteum, or placenta; Manufacture of a physiologically active substance from —. S. Fränkel and E. Herrmann, Vienna. Ger. Pat. 306,906, 13.1.14. Int. Conv., 9.1.14. Addition to Ger. Pat. 297,392.

THE tissue is extracted with acidulated water, proteins are separated, and the solution concentrated *in vacuo*. The remainder of the proteins, together with some of the phosphatides, are precipitated with alcohol, and the concentrated solution is extracted with ether or a similar solvent. After precipitation of the phosphatides and evaporation of the solvent, the residue is treated with water, cooled and freed from fats, again concentrated, and extracted with ether or a similar solvent. As an alternative method of preparation, the tissue may be dehydrated, extracted with a solvent which does not dissolve water, and the phosphatides precipitated from the solution. After evaporation of the solvent, the residue is treated as before. The product obtained by evaporating the final extract is a brown oil containing cholesterol; if the oil is cooled the cholesterol and its esters crystallise out and can be separated, leaving the pure product.—L. A. C.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

[Photomechanical] printing plates; Process for preparing —. A. J. Hain, Lakewood, Ohio, U.S.A. Eng. Pat. 119,328, 7.11.17. (Appl. 16,254/17.)

THE plate to be etched is provided with a layer of regularly spaced dots of the minimum size required for the high lights of the finished printing plate, which dots act directly or indirectly as a resist and which in subsequent processes can be caused to expand laterally to correspond with the photographic image impressed on the plate. For example, a zinc plate coated with an acid resist, such as bitumen, is provided with a sensitised film, e.g. of bichromated gelatin. This is then exposed behind a suitable screen plate and the unexposed portions removed in the usual way leaving a layer of regularly spaced isolated dots. These are impregnated with light-sensitive silver bromide by treatment with ammonia, potassium bromide, and silver nitrate, and the intervening spaces are filled in with gelatin. The plate is then exposed through a negative, developed, fixed, and washed, and treated with a mixed potassium bichromate-ferricyanide-bromide solution; by standing about 15 mins. after this treatment the gelatin round each dot becomes hardened to an extent, in area, proportional to the amount of silver, i.e., to the exposure through the negative. The remaining soluble portions of the film are washed away, the acid resist removed from the same areas by a suitable solvent, and the plate etched as usual. Other methods of obtaining the regularly spaced light-sensitive dots may be used and the method of enlarging them laterally may be varied; a print contact method, a physical development method, and a lead intensification method are described.

—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Cellulose and nitrocelluloses. A. Hervé. *Monit. Scient.*, 1918, **62**, 193—196.

NITROCELLULOSE prepared for the manufacture of celluloid contains small proportions of sulphuric acid combined in the form of esters and not removable by simple washing. This sulphuric acid is retained as a relatively stable combination in the presence of bases, when it reacts as an ester salt, but is progressively eliminated by hydrolysis on boiling with dilute mineral acids. For the determination of the combined sulphuric acid, 5 grms. of the fully washed and dry nitrocellulose is boiled under a reflux condenser for 8 hours with 250—300 c.c. of water containing 1 c.c. of strong hydrochloric acid (sp. gr. 1.18). The nitrocellulose is filtered off, the filtrate and washings are concentrated to 150 c.c. and the sulphuric acid precipitated as barium sulphate. The percentage of sulphuric acid fixed varies with the proportion of that acid used in the nitrating mixture. With a constant proportion of about 19% of water, the following results were obtained:—ratio of HNO_3 to H_2SO_4 1:1, 0.0505% sulphuric acid fixed in the nitrocellulose; ratio 1:2, 0.2025%; ratio 1:3, 0.4290%; ratio 1:4, 1.34%; ratio 1:5, 1.81%. This combined sulphuric acid has a strongly depressing influence on the heat test stability of the nitrocellulose and of the celluloid prepared from it, but it is not the only factor. Compounds of low degrees of nitration or of oxycellulose or hydrocellulose also affect stability; these are most easily eliminated by boiling with alkaline water, so that effective stabilisation demands both acid treatment for the sulphuric esters and basic treatment for the inferior nitrated products. This combination of conditions may be produced by boiling the nitrocellulose with a readily dissociable salt, such as 0.1—1.0% of its weight of magnesium chloride, for about 12 hours. Satisfactory products are thus obtained which withstand the Abel heat test for 60 minutes.—J. F. B.

Mercury fulminate; Detection and determination of free mercury in —. P. Nicolardot and J. Boudet. *Ann. Chim. Analyt.*, 1918, **23**, 206—207.

ONE grm. of the sample is agitated with 100 c.c. of water containing 5 grms. of ammonium thiosulphate; the fulminate dissolves rapidly whilst the free mercury which may be present remains as a grey powder or as small metallic globules. The mercury is collected on a tared filter, washed with water, then with alcohol and ether, dried over potassium hydroxide, and weighed. The quantity of free mercury present is about 0.1% when the fulminate is made in the usual way, but increases if larger proportions of mercury are used in the preparation.—W. P. S.

[Explosives from] glycols. Hibbert. See XX.

PATENT.

Explosive. O. B. Carlson and E. F. Otterdahl. Mousho, Sweden. U.S. Pat. 1,277,033, 27.8.18. Appl., 8.12.15.

The explosive contains ammonium perchlorate, ferrosilicon, wood-meal, a combustible, consisting of fractions from rock-oil rich in naphthenes and having a boiling point above 250°C ., and a substance obtained by gelatinising liquid trinitrotoluene with nitrocellulose and sodium nitrate.

—T. St.

XXIII.—ANALYSIS.

Calibrating pipettes; Simple method of rapidly and accurately —. S. English. *J. Soc. Glass Tech.*, 1918, **2**, 216—219.

ONE neck of a Woulfe's bottle is connected to an elevated reservoir of water, and an outlet near the bottom of the bottle is fitted with a three-way tap leading to a pipette with a pear-shaped bulb of about 0.5 c.c. less capacity than the pipette to be calibrated and a capillary stem above the bulb to bring the capacity up to the required figure. The lower pipette is calibrated from a standard pipette fitted into the other neck of the Woulfe's bottle. The standard pipette is filled with water from the reservoir and the surplus water is removed from its upper extremity by means of blotting paper. The three-way tap is then opened so as to allow the water from the standard pipette to run back into the bottle and force out an equal quantity into the pear-shaped pipette, and after a pre-arranged time for drainage, the height of the water in the capillary tube is marked thereon. The pear-shaped pipette is then emptied. The standard pipette is then replaced by the pipette to be calibrated, which is filled and emptied in a similar manner, except that when the water has risen to the mark on the capillary tube (after allowing the requisite time for drainage) the level of the water in the higher pipette is marked thereon. The maximum error found when comparing this method with the customary one in which the water run out of the pipette is weighed was 0.027 c.c. in a series of twelve 50 c.c. pipettes, but the new method only requires about 2 minutes per pipette.

—A. B. S.

Thymolsulphophthalcin; Use of — as indicator in acidimetric titrations. A. B. Clark and H. A. Lubs. *J. Amer. Chem. Soc.*, 1918, **40**, 1443—1448.

THYMOLSULPHOPHTHALEIN, an indicator having two useful working ranges (see this J., 1916, 980), can be very successfully employed in many differential acidimetric and alkalimetric titrations. To illustrate the general method of employment, a few typical titrations are described (mixtures of benzoic and hydrochloric acids, acetic and hydrochloric acids, acetic and sulphuric acids, titration of aniline by hydrochloric or sulphuric acid). Any acid with a dissociation equal to or weaker than that of acetic acid may be differentially titrated in the presence of hydrochloric acid, provided that the weaker acid is completely neutralised when the alkaline colour change of the indicator occurs. The use of proper colour screens or, preferably, of a colorimeter or spectrophotometer greatly increases the accuracy of differential titrations but is not absolutely necessary.—H. W.

Copper; Separation of traces of — from solution. J. E. Saul and D. Crawford. *Analyst*, 1918, **43**, 348.

WATER containing as little as 0.002% of copper gives a voluminous yellow precipitate when treated with 0.1% of quinosol (the potassium salt of 8-hydroxy-quinoline-5-sulphonic acid) and allowed to stand for about 18 hrs. The precipitate is soluble in dilute hydrochloric acid. Other metals in very dilute solution do not give a reaction, but a precipitate is obtained when a concentrated solution of a mercuric salt is treated with the reagent.—W. P. S.

Zinc dust [for analysis]. O. Binder. *Chem.-Zeit.*, 1918, **42**, 458.

THE author has found that zinc dust contains appreciable amounts of chlorine, for which allowance must be made in certain analytical processes.

Zinc; Volumetric estimation of —. R. Howden.
Chem. News, 1918, 117, 322.

Zinc when present as chloride in solutions which contain no heavy metal or ammonium salts may be estimated by first boiling to remove excess of free acid, exactly neutralising with N/10 sodium hydroxide using methyl orange as indicator, and then titrating the acid combined with the zinc with N/10 sodium hydroxide, using phenolphthalein as indicator. Towards the end of the reaction the solution is boiled and the end-point taken as that point at which the pink colour is not destroyed by boiling.—J. F. S.

Colloidal hydroxides; Adsorption of —. K. Scherlinga. Pharm. Weekblad, 1918, 55, 1070—1074.

The adsorption of ordinary salts by metallic hydroxides is not of much practical significance in analysis. In separating iron, it is not desirable to have a great excess of alkali.—A. J. W.

Barium and strontium; Separation and determination of —. F. A. Gooch and M. A. Soderman. Amer. J. Sci., 1918, 46, 538—540.

STRONTIUM chloride is soluble in a mixture of hydrochloric acid and ether, whilst barium chloride is precipitated. About 0.5 gram. of the mixed chlorides, containing not more than 0.3 gram. of strontium chloride, is dissolved by warming with the least possible quantity of water, and the cold saturated solution is treated with a mixture of concentrated hydrochloric acid, 4, and ether, 1 vol., added slowly, with stirring. The precipitated barium chloride is collected on an asbestos filter, washed with the acid-ether mixture, dried at 150° C., and weighed. The error does not exceed 0.0004 gram.—W. P. S.

Iron; Titanium chloride as a reducing agent in the determination of — by titration with permanganate in hydrochloric acid solution. L. Brandt. Chem.-Zeit., 1918, 42, 432—434, 450—451.

TITANIUM trichloride solution readily reduces ferric salts in the cold (Knecht and Hibbert, this J., 1903, 232, 762), the reduction being made either by adding the exact quantity of titanium trichloride, or by adding more than this and then removing the excess by the addition of copper sulphate. The ferrous salt is then titrated in the usual way with permanganate solution. Platinum chloride, potassium bichromate, and arsenic acid do not interfere with the method, but arsenious acid should not be present. When stannous chloride is used for reducing the ferric salt, copper sulphate may be employed in place of mercuric chloride for removing the excess of stannous chloride added.—W. P. S.

Gasometric [nitrogen] determinations; Simplified —. A. Renaud. J. Pharm. Chim., 1918, 18, 104—106.

FREQUENT standardisations with pure urea may be avoided in the determination of nitrogen in urine by using a comparison tube exactly similar to the nitrometer. This comparison tube contains a volume of air equal to the volume of nitrogen liberated in the nitrometer from a known quantity of urea; the volume of air then serves as a standard in subsequent determinations. It is necessary to note the pressure and temperature at the time the air is admitted to the comparison tube. (See also J. Chem. Soc., Nov., 1918.)—W. P. S.

Carbon; Determination of total — in various biological substances. A. Renaud. J. Pharm. Chim., 1918, 18, 106—108.

THE substance (e.g., urine) is heated in a flask with potassium bichromate and sulphuric acid, the gases evolved are passed into ammoniacal calcium

chloride solution, and the resulting calcium carbonate is separated and determined volumetrically. After the absorption of the carbon dioxide it is usually necessary to heat the ammoniacal solution on a water-bath in order to obtain the calcium carbonate in a condition suitable for titration. If barium chloride is used in place of calcium chloride, the resulting barium carbonate may be collected on a filter at once, converted into barium sulphate, and weighed. (See also J. Chem. Soc., Nov., 1918.)

—W. P. S.

Magnetic susceptibility of mixtures of liquids. Alphens W. Smith and Alva W. Smith. J. Amer. Chem. Soc., 1918, 40, 1218—1224.

THE magnetic susceptibility of liquid mixtures is found to satisfy the simple mixture rule within the limits of experimental errors. Data are recorded for mixtures of acetone and water, acetic acid and water, acetic acid and benzene, acetone and ethyl alcohol, and it is suggested that the measurement of the magnetic susceptibility may conveniently be used in the determination of the composition of binary liquid mixtures.—H. PATENTS.

Moisture; Means for detecting or measuring —.

C. A. Parsons and A. H. Law, Newcastle-on-Tyne. Eng. Pat. 119,533, 4.10.7. (Appl. 14,352/17.)

A LAYER of electric insulating material is wound on a metal cylinder, and an open coil of wire is wound on the insulation. The insulation resistance through the material from the wire to the cylinder is measured by any suitable means, and its variation due to the variable humidity of the air is a measure of that humidity. In a modification the terminal elements consist of two coils of wire wound on the insulation, and the surface resistance between them is measured. The method is suitable for testing the air used for cooling dynamo-electric machinery, the insulation employed in the test being similar to that used in the machinery.

Glassware. Eng. Pat. 119,297. See VIII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Antonoff. Catalysis. 18,020. Nov. 4.

August. Treating liquids or solids for heating, calcining, vaporising, or decomposing them. 17,799. Oct. 31.

Conradi, Crawford, and Lyall. Apparatus for filtering, scrubbing, or conditioning air, gases, and liquids. 18,290. Nov. 8.

Diebold. Manufacture of dispersions or suspensions of matter. 18,312. Nov. 8.

Dressler Tunnel Owens, Ltd., and Williamson. Drying or heating apparatus. 17,895. Nov. 1.

Gourlay and Sands. Apparatus for separating immiscible liquids. 17,520. Oct. 28.

Johnston. Dehydrators for drying vegetable, animal, and mineral substances. 17,530 and 18,346. Oct. 28 and Nov. 8.

Mann. Drying, concentrating, or evaporating liquids etc. 18,017. Nov. 4.

Soddy. Improving or restoring absorptive power of charcoal for gases. 17,583. Oct. 28.

Stubley. Separating machine. 17,866. Nov. 1.

Tansley. Apparatus for cooling gases. 17,821. Oct. 31.

Titan Co. Aktieselskabet. Freeing liquids from particles suspended therein. 17,811. Oct. 31.

(Norway, 12.12.17.)

Torrance. Disk etc. grinding-mills. 18,127. Nov. 5.

Urruty. 18,343. See XIX.

Welch. Method of concentrating solutions. 17,696. Oct. 30.

West. Kilns. 18,228. Nov. 7.

Winkel. Filtering-tanks. 18,008. Nov. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

15,347 (1917). Blom and Gledie. Machines for drying liquids. (110,753.) Nov. 6.

15,974 (1917). Smallwood. Furnaces. (120,259.) Nov. 13.

17,118 (1917.) Price and Sugg. Drying apparatus. (120,283.) Nov. 13.

218 (1918). Hilton and Willis. Apparatus for bringing gases and liquids into intimate contact. (120,304.) Nov. 13.

1154 (1918). Blacker. See VII.

1171 (1918). Soc. d'Exploit. de Proc. Evapora-

toires Système Prache et Bouillon. Evaporating and crystallising apparatus especially adapted for obtaining large crystals. (112,943.) Nov. 6.

2564 and 10,231 (1918). Brownlow. Centrifugal separators. (120,319.) Nov. 13.

3997 (1918). Kilburn (Sulzer frères). See II.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Aitches, Ltd., and Fabini. Incandescent gas mantles, and manufacture thereof. 18,248. Nov. 7.

Baines. Composite fuel. 17,557. Oct. 28.

Barbet et Fils et Cie. Removing tar from products of distillation of wood, coal, etc. 18,026. Nov. 4. (Fr., 3.11.17.)

Bataafsche Petroleum Maatschappij. Rectification of hydrocarbons. 17,741 and 18,270. Oct. 30 and Nov. 7. (Holland, 21.2 and 1.3.18.)

Burnett. Apparatus for washing coal etc. 17,873. Nov. 1.

Burnett. Extracting water etc. from washed coal etc. 17,874. Nov. 1.

Coxon and Williams. Renewal of filaments in metal filament electric lamps. 18,370. Nov. 9.

Davidson. Manufacture of peat fuel from damp peat. 17,843. Oct. 31.

Deltwick, and Techno-Chemical Laboratories, Ltd. Combustion of fuel. 18,392. Nov. 9.

Ellison, Wilkinson, and Woodhouse. Retorts for continuous carbonisation of coal etc. 17,782. Oct. 31.

Griggs. Hydrogen generators. 18,382, 18,383, 18,384. Nov. 9.

Kirke. Burning gaseous fuel. 17,918. Nov. 1.

Michel and Raskin. Manufacture of briquettes from flue dust, sawdust, etc. 17,945 and 17,946. Nov. 2.

Rinman. Process of dry distillation with strong bases of mixtures of carbon acids and mixtures thereof with substances containing lignin. 17,718. Oct. 30. (Sweden, 8.11.17.)

Sleeman. 18,337. See XIX.

Smith. Briquettes and method of making same. 17,693. Oct. 30. (U.S., 15.11.16.)

Soddy. 17,583. See I.

Wade (Le Petit). Production of fuels. 18,039. Nov. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

18,335 (1916). Chamier, Craig, and Moeller. Manufacture of power gas and recovery of hydrocarbon oils. (120,051.) Nov. 6.

10,973 (1917). Wellington. Destructive distillation of carbonaceous substances. (120,223.) Nov. 13.

13,954 (1917). Day. Apparatus for producing hydrocarbons. (120,230.) Nov. 13.

15,868 (1917). Dubbs. Treatment of petroleum and other hydrocarbons to produce hydrocarbons having lower boiling points. (112,010.) Nov. 6.

15,885 (1917). Hutchins. Manufacture of carbon blocks. (120,255.) Nov. 13.

16,898 (1917). Day, Macdonald, and Day. Formation of hydrocarbons having low boiling points from hydrocarbons having high boiling points. (113,264.) Nov. 13.

16,899 (1917). Day and Day. Vaporising hydrocarbons and producing hydrocarbons having low boiling points from hydrocarbons having high boiling points. (119,440.) Nov. 13.

16,900 (1917). Day and Day. Treatment and refining of hydrocarbon materials. (119,441.) Nov. 6.

18,578 (1917). Key. Apparatus for distilling or carbonising coal and cannel. (120,139.) Nov. 6.

3997 (1918). Kilburn (Sulzer frères). Cooling hot residues from distillation processes. (120,329.) Nov. 13.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Barbet et Fils et Cie. 18,026. *See* II.
 Barrett Co. Recovery of pyridine bases. 17,663.
 Oct. 29. (U.S., 17,118.)
 Batnafsche Petroleum Maatschappij. 17,741 and
 18,270. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

A'Brassard and Crawford, and Singer. Manu-
 facturing colouring matters. 18,016. Nov. 4.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Dawson and Dyson. Preparing textile fibres for
 spinning. 17,606. Oct. 29.
 Gray and Jardine. Preparation of bamboo in
 paper-making. 17,711. Oct. 30.
 Spicer (Shirlow). Impregnating and drying
 strawboard, paper, etc. containers. 17,902 and
 17,906. Nov. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

15,467 (1917). Spicer (Wells). Production of
 paper pulp. (120,086.) Nov. 6.
 298 (1918). Blyth. Paper-making machines.
 (120,147.) Nov. 6.
 2046 (1918). Herrox. Substitute for cardboard,
 strawboard, etc. (120,157.) Nov. 6.

VI.—BLEACHING; DYEING; PRINTING;
FINISHING.

APPLICATIONS.

Bright and Bros., and Evans. Machines for boil-
 ing, bleaching, dyeing, sizing, etc. yarns or fabrics.
 17,620. Oct. 29.
 Poulson. Rendering textile fabrics etc. water-
 proof and fireproof. 17,683. Oct. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

1137 (1918). Calico Printers' Assoc., Ashton, and
 Nelson. Printing cotton fabrics or yarns. (120,152.)
 Nov. 6.
 10,299 (1918). Calico Printers' Assoc., Fothergill,
 and Wilson. Treatment of insoluble natural gums
 for the production of thickenings suitable for
 calico and other textile printing and finishing etc.
 (120,183.) Nov. 6.

VII.—ACIDS; ALKALIS; SALTS; NON-
METALLIC ELEMENTS.

APPLICATIONS.

Aanensen. Manufacture of ammonium per-
 chlorate. 17,700. Oct. 30. (Norway, 22,1217.)
 British Dyes, Ltd., Davidson, and Turner. In-
 creasing production and efficiency in contact plants
 in manufacture of sulphuric acid. 17,869. Nov. 1.
 British Dyes, Ltd., Davidson, and Turner. Manu-
 facture of pure sulphur dioxide. 17,870. Nov. 1.
 British Dyes, Ltd., Davidson, and Turner. Pro-
 duction of nitrous anhydride and nitrites from
 nitrates or waste nitric acid. 17,871. Nov. 1.
 British Dyes, Ltd., Davidson, and Turner. Con-
 tinuous process for production of high strengths of
 oleum. 17,872. Nov. 1.
 Cain, Couch, and Powell. Manufacture of alkali
 permanganate. 17,582. Oct. 28.
 Calvert. Production of cyanide. 18,131. Nov. 5.
 Craig, and Spence and Sons. Recovery of sul-
 phur. 17,691. Oct. 30.
 Craig. Recovering potash etc. from blast fur-
 naces. 17,974. Nov. 4.

Delage. Manufacture of magnesia. 18,335.
 Nov. 8. (Fr., 8,11,17.)

Grayson. Manufacture of sulphur dioxide.
 17,813. Oct. 31.

Grayson. Manufacture of sodium nitrite. 17,811.
 Oct. 31.

Griggs. 18,382, 18,383, 18,384. *See* II.

Heberlein. Electrolysing solution of nickel salt.
 17,650. Oct. 29.

Imperial Trust for the Encouragement of Scien-
 tific and Industrial Research, and Stannard.
 Recovery of tungstic acid from ores. 18,206.
 Nov. 6.

Maconochie and de Ros. Oxidation of tin and
 production of tin oxide, also treatment of zinc
 and zinc-containing materials for production of zinc
 oxide. 17,749. Oct. 30.

Norsk Alkali Aktieselskabet. Electrolysis of
 chlorides of alkaline metals. 18,135. Nov. 5.
 (Norway, 13,12,17.)

Ridoni, and Soc. Talco e Grafite Val Chisone.
 Purification of natural graphites. 18,330. Nov. 8.

Sheard. Producing neutral sulphate of ammonia.
 18,362. Nov. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

10,780 (1917). Statham. Light precipitated chalk
 and processes of making same. (120,219.) Nov. 13.
 12,289 (1917). Huber and Reath. *See* IX.
 1154 (1918). Blacker. Apparatus for breaking up
 or pulverising caustic soda and the like. (120,309.)
 Nov. 13.

VIII.—GLASS; CERAMICS.

COMPLETE SPECIFICATION ACCEPTED.

5764 (1917). Glossop and Sherlock. Continuous
 kilns for burning bricks, terra cotta, etc. (120,052.)
 Nov. 6.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Anderton and Coates. Cement. 18,379. Nov. 9.
 Bäärnhielm. Manufacture of cement. 17,717.
 Oct. 30. (Sweden, 24,12,17.)
 Cullis. Concrete etc. 18,190. Nov. 6.
 Harland and Wolff, and Marks. Concrete.
 17,901. Nov. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

5764 (1917). Glossop and Sherlock. *See* VIII.
 12,289 (1917). Huber and Reath. Producing
 cement and recovering potassium compounds.
 (110,540.) Nov. 6.

X.—METALS; METALLURGY, INCLUDING
ELECTRO-METALLURGY.

APPLICATIONS.

Bloxam (Stabilimenti Biak—Ing. A. Pouchain).
 Tin-soldering and tin-coating aluminium and
 aluminium alloys. 17,739. Oct. 30.
 Bloxam (Stabilimenti Biak—Ing. A. Pouchain).
 Aluminium alloys. 17,743. Oct. 30.
 Coxon and Williams. 18,370. *See* II.
 Craig. 17,974. *See* VII.
 Hall, and Rolls Royce, Ltd. Aluminium alloy.
 17,579. Oct. 28.
 Imperial Trust, and Stannard. 18,206. *See* VII.

XII.—FATS; OILS; WAXES.

APPLICATION.

Schuck, and Superior Oil and Process Co. Treatment of solid fatty materials. 18,032. Nov. 4.

COMPLETE SPECIFICATION ACCEPTED.

1412 (1918). Winters. Apparatus for extracting oil from seeds, beans, nuts, offal, etc. (120,156.) Nov. 6.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Kidd, and Wilkinson, Heywood, and Clark. Formation of pigments etc. 17,726. Oct. 30.
Kühler. Production of shellac substitute. 18,253. Nov. 7. (Sweden, 23,10,17.)
MacKenzie. Dissolving and breaking down shellac for hat manufacture etc. 17,592. Oct. 28. (Australia, 11,6,18.)
Nicholson. Dope for aeroplanes. 18,373. Nov. 9.

COMPLETE SPECIFICATION ACCEPTED.

10,299 (1918). Calico Printers' Assoc., and others. *See* VI.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

North British Rubber Co. (Goodyear Tyre and Rubber Co.). Manufacture of caoutchouc substances. 17,968. Nov. 2.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Devonshire and Ford. Manufacture of plastic compositions from vegetable ivory etc. 18,140. Nov. 5.
Kay and Platt. Tanning hides etc. 18,305. Nov. 8.
Lansdown and Magnus. Treatment and utilisation of scrap and waste leather. 17,629. Oct. 29.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Dederich. Manufacture of fertilising material. 17,851. Oct. 31.

COMPLETE SPECIFICATION ACCEPTED.

17,900 (1917). Truffaut. Fertiliser and insecticide. (120,288.) Nov. 13.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Clark, Clark, and Hood. Decolorising and purifying saccharine materials. 18,042. Nov. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

10,629 (1917). Simpson and Lyle. Means for treating sugar liquors. (120,055.) Nov. 6.
10,299 (1918). Calico Printers' Assoc., and others. *See* VI.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Greville. Malt products. 18,001. Nov. 4.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Albanese. Treatment of milk. 18,245. Nov. 7.
Greville. Treatment of flour and production of baking powder, self-raising flour, etc. 17,988. Nov. 4.
Grossmann. Treatment of sewage sludge. 17,524. Oct. 28.
Sleeman. Liquor for potable or power purposes and method of producing same. 18,337. Nov. 8.
Urruty. Disinfectant for cleaning condensers and boilers. 18,343. Nov. 8. (Fr., 20,12,17.)
Watkins. Butter substitute. 17,633. Oct. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

16,828 (1917). Kellogg and Kazmann. Food beverage and process of producing same. (120,121.) Nov. 6.
16,830 (1917). Kellogg and Kazmann. Food beverage and process of producing same. (120,279.) Nov. 13.
18,524 and 18,525 (1917). Uecke. Processes and apparatus for softening water. (120,293 and 120,294.) Nov. 13.
5060 (1918). Makin. Foodstuffs and the manufacture thereof. (120,166.) Nov. 6.
9224 (1918). De Groussan and Viconge. Treatment of cocoa and waste products of chocolate manufacture. (120,178.) Nov. 6.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

COMPLETE SPECIFICATIONS ACCEPTED.

15,395 (1917). Tcherniac. Manufacture of oxyalkyl ethers of *p*-acetaminophenol or substitution products thereof. (120,081.) Nov. 6.
4684 (1918). Bloxam (Elektrizitätswerk Lonza). Manufacture of ethyl alcohol from acetaldehyde. (120,163.) Nov. 6.

XXII.—EXPLOSIVES; MATCHES.

APPLICATION.

Aronson. Matches. 17,848. Oct. 31.

XXIII.—ANALYSIS

APPLICATION.

Aktiebolaget Ingeniörsfirma F. Egnell. Registering mechanism for gas-analysing apparatus. 17,912. Nov. 1. (Sweden, 8,11,17.)

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Drying air. F. O. Rynoe, London, Eng. Pat. 119,590, 8.1.18. Appl. 462/18.

COMPRESSED air is delivered into the top of a cylindrical chamber having a conical bottom. A loaded air-escape valve is provided near the top of the chamber, and a long vertical drain pipe extends downwards from the apex of the conical bottom and terminates in another loaded valve. Owing to the compression, the air deposits its moisture, and this passes down the drain pipe and is discharged through the valve, which opens only at a pressure equal to that of the air-escape valve plus the pressure due to the column of liquid in the drain pipe. The dried air escapes from the upper loaded valve.—W. H. C.

Dryer. A. W. Lissauer, New York, U.S. Pat. 1,277,961, 3.9.18. Appl., 14.12.17.

THE air inlet and outlet passages, which are connected with chambers in the dryer, have varying cross-sectional areas. A fan supplies preheated air to the inlet passages at their greatest cross-section and withdraws a controlled proportion of air from the outlet passages at their greatest cross-section.—W. H. C.

Dryer; Rotary —. W. O. Arzinger, Nashville, Tenn. U.S. Pat. 1,278,288, 10.9.18. Appl., 1.11.17.

THE apparatus consists of an insulated cylinder provided at the inlet end with electrical heating units, which project inwards from the walls of the casing and propel the material forward. In the other portion of the cylinder the material is propelled forward by means of a series of vanes inclined angularly to the longitudinal axis of the cylinder.—J. H. P.

Drying apparatus with a column of receptacles movable through a drying shaft. F. H. Schule G.m.b.H., Hamburg, Ger. Pat. 306,987, 24.2.16.

THE compartments of the apparatus, one above another, are each provided with an inlet for fresh hot dry air on one side and an air outlet on the opposite side. The inlet of one compartment is on the opposite side to that of the next above or below, so that the material is traversed by air alternately in opposite directions.—J. H. L.

Air blast; Process and apparatus for drying — by means of calcium chloride. L. Honigmann, Aix-la-Chapelle, Ger. Pat. 307,221, 15.7.17.

CALCIUM chloride solution is distributed over a number of containers in a closed vessel; hot gas or air is blown through the vessel to evaporate the solution and dry the calcium chloride, and then the blast to be dried is passed through. In the apparatus claimed the containers consist of trays situated one above another, with alternate central and peripheral gaps, to allow the solution introduced at the top of the vessel to overflow from one tray to another until all are filled, and to afford a baffled passage for the air or gas passed through the vessel.—J. H. L.

Furnace walls. E. Bernitz, South Boston, Mass., U.S.A. Eng. Pat. 119,599, 21.1.18. (Appl. 1188/18.)

A FURNACE wall is provided with an internal air chamber, and the bricks on the furnace side of the chamber are spaced apart to provide a series of openings into the fuel bed. The openings are largest at the middle plane of the fuel bed and decrease in size above and below this level. A

forced draught is delivered to the air chamber through a valve-controlled opening, to cool the furnace wall and prevent the formation of clinker in contact with it. The bridge-wall of the furnace is also provided with air ducts for supplying a regulated quantity of air to the fuel bed.—W. F. F.

Separators; Centrifugal —. K. and A. Ward, Stockholm, Sweden, Eng. Pat. 119,612, 11.7.18. (Appl. 11,392/18.)

A hollow horizontal shaft rotating within a stationary outer casing carries a body portion in which a number of separating channels inclined to the axis are provided. The fluid to be separated is fed to the channels at a point between their inner and outer ends. During the separating operation the outer casing is filled with a fluid at such a pressure that the fluid to be separated and its content of particles of less or the same specific gravity are prevented from being thrown out into the outer casing, whilst the heavier particles pass through.—W. H. C.

Separator; Centrifugal — for separating solid and liquid mixtures. W. Mauss, Johannesburg, Eng. Pat. 119,706. (Appls. 14,785, 12.10.17, and 5636, 2.4.18.)

IN a centrifugal filter, the filtering drum is composed of two conical members, 1, 2, carried by shafts, 18, 11, respectively. The hub, 14, of the member, 1, carries pins, 17, sliding in the member, 2, so that the two members may be separated axially. Perforated plates, 5, are sunk in the walls of the cones and are covered with filtering cloth, the filtered liquid being discharged through the passages, 8, to the receiver, 9. The two conical members are locked together by a toggle mechanism rotating with the shaft and operated by means of a hydraulic cylinder through suitable levers. The

toggle mechanism is such that the drum and shafts may be lowered as a whole till the outlet holes, 8, are below the rim of the liquid discharge chamber, 9, whereupon further lowering of the shaft, 11, opens the toggle and separates the drum sections, so that the solid matter is discharged into the chamber, 10. The drum sections are then closed and the drum raised to its normal position for a fresh charge, and means are provided to operate the hydraulic cylinder so as to effect this cycle automatically. The pulp to be separated is fed by a pipe, 58, to a reciprocating bucket, 59, which discharges it periodically into the shoot, 16, and thence into the drum. The bucket, 59, is hydraulically operated synchronously with the movements of the drum.—W. F. F.

Centrifugal separator. P. T. Sharples, St. Davids, Pa., Assignor to Sharples Specialty Co., West Chester, Pa. U.S. Pat. 1,277,653, 3.9.18. Appl. 6,11.17.

A ROTARY vertical bowl is provided with an inner removable non-perforated liner. The latter

consists of an upper section which is of greater diameter and has inwardly extending ends and is connected with a lower section of less diameter. The mixture is fed into the bottom section and the solid portion is delivered by centrifugal action into the upper section, where it is retained, any entrained liquid draining back into the lower section.—W. H. C.

Filter; Chemical — W. R. Beckley, Assignor to General Filtration Co., Inc., Rochester, N.Y. U.S. Pat. 1,277,832, 3.9.18. Appl., 27.2.15.

THE bottom and sides of the filter tank are lined with plates spaced apart, and a filtering bed of porous tiles, also spaced apart, is formed a short distance above the bottom plates. The spaces between the plates are filled with binding material.—W. H. C.

Distilling; Process and apparatus for — A. B. Foster, Washington, D.C. U.S. Pat. 1,277,895, 3.9.18. Appl., 15.2.13.

IN a cyclic process, the substance to be distilled is caused to traverse a vaporising vessel against a counter-current of gas maintained at a suitable temperature and below atmospheric pressure. The gaseous mixture issuing from the vessel is compressed and cooled, part of the vapour being condensed and separated. The pressure of the remainder is then reduced, and an interchange of heat effected between the compressing and expanding means, provision being made for transmitting kinetic energy from the latter to the compression pump.—W. E. F. P.

Concentrating apparatus. N. L. Heinz and J. W. Geib, La Salle, Ill. U.S. Pat. 1,277,922, 3.9.18. Appl., 15.9.15.

A NUMBER of separate furnaces and evaporating pans are set in a row under a common roof, and the fumes are conveyed by a common passage to a series of towers.—W. H. C.

Evaporating apparatus. J. H. Fedder, New York. U.S. Pat. 1,278,127, 10.9.18. Appl., 11.7.11. Renewed 6.11.17.

A STREAM of atomised liquid is projected horizontally into a horizontal chamber, and the spray is dried and held in suspension by jets of heated air projected horizontally below and in the same direction by nozzles arranged along the lower wall of the chamber. The horizontal chamber discharges into the top of a vertical cylindrical chamber, which is provided with openings in its cylindrical walls inclined to the axis, through which air is projected tangentially into the chamber. The top of the horizontal chamber is constituted by a screen formed as an endless band, and the band and air nozzles are oppositely electrified, so that particles are intercepted by the screen and removed.—W. E. F.

Boiling machine. E. D. Jefferson, Boston, Mass. U.S. Pat. 1,278,155, 10.9.18. Appl., 19.1.17.

THE machine consists of an outer rotating cylindrical tank containing a perforated cage which rotates with the tank, and steam pipes between the tank and the cage. Exhaust valves and means for controlling the supply of steam and solution are also provided, and these can all be operated while the tank is rotating.—R. V. S.

Heat-exchanger; Fractional condensing — and process for fractionating liquids. E. H. Wright and E. H. Atwood, Olean, Assignors to Vacuum Oil Co., Rochester, N.Y. U.S. Pats. (A) 1,278,279 and (B) 1,278,280, 10.9.18. Appls., (A) 18.6, (B) 19.12.17.

(A) A NUMBER of sections are arranged one above the other in a casing, each section consisting of a number of oil pipes with a collecting pan below for the condensed liquid, a steam preheater, and a steam spray pipe in the pan. The oil flows downwards in a zigzag direction through the sections, and is preheated, and the vapour passes in a zigzag direction upwards and is fractionally condensed. (B) The liquid to be fractionated is distilled and the vapour is passed through the foregoing apparatus, when the different fractions are condensed by the different sections of the condenser. The vapour also superheats steam, which is then sprayed into the collecting pans to re-evaporate fractions lighter than those desired.—J. H. J.

Fire extinguisher composition. H. S. Mork, Brookline, Mass., Assignor to American La France Fire Engine Co., Inc., Elmira, N.Y. U.S. Pats. (A) 1,278,714, (B) 1,278,715, and (C) 1,278,716, 10.9.18. Appl., 14.1.18.

THE composition comprises as essential ingredients. (A) a potassium salt of carbonic acid, e.g., potassium carbonate, and an alkali lactate, e.g., sodium lactate, (B) sodium bicarbonate and sodium lactate, or (C) an alkali salt of carbonic acid, e.g., sodium bicarbonate, and an alkali citrate, e.g., potassium citrate.—J. H. P.

Crystal masses; Method for obtaining large — with well-formed crystals from hot concentrated liquors. E. Waskowsky, Dortmund, Ger. Pat. 306,173, 10.1.14.

THE liquor is cooled by allowing it to fall freely in a fine state of division. Attaining a state of supersaturation due to supercooling, the drops fall into the crystallising vessel. The concentration at the surface of the liquor in the crystallising vessel is that corresponding to saturation, and the drops being supersaturated, and consequently heavier than the surface liquor, sink to the bottom, so that the crystals are built up on the bottom and sides of the crystallising vessel.—J. S. G. T.

Spraying liquids; Siphon for — H. Petersen, Berlin-Steglitz. Ger. Pat. 307,312, 14.9.17.

IN the lower of two superposed vessels is a float, the hollow stem of which passes up into the upper vessel. The stem of the float carries a ball-valve which when in position, determined by the height of the float, shuts off communication between the two vessels except by way of the hollow stem. The liquid entering the upper vessel, reaches the level of the top of the hollow stem and passes into the lower vessel by way of the stem. The float rises, the ball valve is opened, and the liquid in the upper vessel passes with a rush into the lower. The lower vessel is emptied of liquid by a siphon tube with a "rose" sprinkler attached to its end. For good spraying the total area of the holes in the sprayer should be less than the area of cross-section of the siphon tube.—J. S. G. T.

Transferring gases from cylinders to the experimental vessel; Arrangements for — in which liquid is used to force the gas out of the cylinder. Hanseatic Apparatebau Ges., vorm. Bremen u. Co., Kiel. Ger. Pat. 307,489, 15.3.17.

A VERY dilute solution of an electrolyte such as a caustic alkali, or an alkali salt, or mixtures

thereof, is added to the liquid employed in order to prevent rust formation in the interior of the cylinder.—J. S. G. T.

Air or other gases; Apparatus for purifying — H. Ider, Zürich. Ger. Pat. 307,579, 20.5.17. Int. Conv., 11.5.17.

PURIFICATION is effected by saturating the air or other gas with vapour and subsequently cooling. The current of air or gas passes through a horizontal cylinder which is divided into four sections in the following order. First a chamber in which are arranged a series of vapour jets above and below the axis of the cylinder. This is followed by a mixing chamber. In the third section the current of gas is cooled by water sprays. The last section is composed of a coke filter bed over which water drips. The water used in the apparatus runs off through drains in the floor of the apparatus.—J. S. G. T.

Gas or air ports for regenerative furnaces. J. Rees, West Hartlepool, and South Durham Steel and Iron Co., Ltd., Stockton-on-Tees. Eng. Pat. 119,826, 15.4.18. (Appl. 6376/18.)

Drying and acrating machine. C. E. and W. M. Clark and J. A. Sparks, Elk City, Kans. U.S. Pat. 1,278,593, 10.9.18. Appl., 22.6.17.

See Eng. Pat. 108,520 of 1916; this J., 1917, 996.

Cooling and evaporating apparatus. Ger. Pat. 307,483. See VII.

Electro-osmosis. Ger. Pat. 307,242. See XI.

IIa. — FUEL; GAS; MINERAL OILS AND WAXES.

By-product coking practice; Some characteristics of American coals in — F. W. Sperr, jun. J. Franklin Inst., 1918, 186, 133–163.

THE growth of by-product coking in the United States is dealt with and statistics are given showing the distribution of the world's supply of bituminous coals and iron ores. The by-product coking process is much more elastic than the beehive process and consequently a considerably wider range of coals is rendered available for coke production. In practice the tendency is to mix a coal of high volatile content with 15% to 30% of a coal low in volatile matter, the mixture containing 30 to 35% volatile matter; a better coke is thus produced for blast-furnace work. The coking quality of a coal is best determined by practical scale tests, several of which may be necessary to find the most suitable conditions of coal preparation, oven construction, and coking regulation. The geological age of a coal is no criterion as to its coking quality. As good by-product yields and as good coke are obtained from the comparatively recent coals of Colorado as from the early carboniferous strata of Pennsylvania. The coking quality seems to bear some relation to the oxygen content of the coal. The highly oxygenated coals of Illinois may have less volatile matter than coal from a portion of the Pittsburgh seam and yet produce a much inferior coke. As a rule coals of high oxygen content require more careful adjustment and regulation of conditions in order to produce a satisfactory coke than is necessary in the case of other coals containing the same percentage of volatile matter but less oxygen. Coke made in by-product ovens retains approximately 10 to 20% less of the sulphur

originally in the coal than that made in beehive ovens.—T. F. E. R.

Benzol and naphthalene recovery [from coal gas]. H. E. Copp. Mid. Assoc. Gas Eng. and Managers, Oct. 31, 1918. Gas J., 1918, 144, 311–313.

THE benzol plant is situated at the inlet to the purifiers and comprises scrubber, heat exchangers, oil superheaters, crude benzol still using live steam, analyser, main condenser, separator, and oil coolers. The process is continuous. The washing medium is creosote, prepared in a tar dehydration plant alongside the benzol plant. When fresh, the creosote contains 20 to 25% of naphthalene and gives the following fractions on distillation: up to 200° C. 8%, 200° to 230° 32%, 230° to 280° 20%, 280° to 300° C. 15%, and residue 25%. After passing through the scrubbers, this creosote contains 2% benzol and retains 0.5% after passing through the still. In order to free the creosote from naphthalene and thereby enable it to wash all the naphthalene out of the gas, a small supplementary condenser or analyser has been inserted between the still and the main condenser and is maintained at a constant temperature of 92°–98° C. The liquids condensed at this point consist chiefly of water and naphthalene, which are collected separately and the latter is recovered for sale. The effect of the analyser is to reduce the naphthalene content of the creosote to 6%, with the result that the gas is entirely free from naphthalene after washing; it contains 16.8 grains per 100 cub. ft. at the inlet to the scrubbers. In addition, the creosote lasts for a longer period and the crude benzol is considerably improved.

—T. F. E. R.

Electric heater for use in the analytical distillation of gasoline. E. W. Dean. J. Ind. Eng. Chem., 1918, 10, 823–826.

NICKEL-CHROMIUM wire is wound round a mandrel of about $\frac{1}{4}$ in. diameter, the helix thus formed is stretched out to a length of about 26 in. and then wound as a spiral on a wooden cone 2 in. high and $1\frac{1}{2}$ in. diameter at the base. The spiral is held in position by brads and a layer of aluminum cement is applied over the whole to a thickness of $\frac{1}{8}$ in. When the cement is set, the wooden cone is removed, the device dried at 100° C., and then baked at 900° C. It is attached to a stout asbestos board which forms the lid of a brass box, so that the cement cone is in an inverted position in the box when the lid is in place. The terminal wires from the cone are connected with binding screws on the lid and the dead space in the box is filled with kieselguhr, shredded asbestos, or magnesia, a silica tube being used to insulate the wire leading from the lower end of the cone. The flask to be heated rests over a hole in the lid immediately over the cone. Sliding wire rheostats are used for regulating the heat.—W. P. S.

Drilling oils and their substitutes; Examination of — J. Marcussen. Mitt. K. Material-prüf., 1918, 36, 107–112.

VARIOUS substitutes have been used in Germany to replace the so-called water-soluble mineral oils used in the drilling of armour plate, etc. Those which are free from oil include sulphite lyes, extracts of vegetable mucilage, and solutions of glue, and are characterised by dissolving in water without forming an emulsion. Sulphite lyes when treated with excess of dilute hydrochloric acid, yield a precipitate of ligninsulphonic acid, which is insoluble in ether or benzene, and is decomposed by strong hydrochloric acid, with the liberation of sulphur dioxide. They reduce Fehling's solution

and solutions of dyestuffs such as Methylene Blue, and give the naphthol-sulphuric acid reaction for carbohydrates. On evaporation sulphite lyes leave about 10% of residue containing 10 to 15% of ash, 1 to 10% of sulphur, and about 0.4% of nitrogen. When used as a substitute for drilling oil they require the addition of alkali as a rust-preventive. The brown specks formed on the metal when strongly alkaline sulphite lyes are used are due to tannin constituents of the lyes. Vegetable mucilage extracts are prepared from seeds such as linseed, and especially from carrageen moss, which is first soaked and then boiled with soft water. Good preparations should give a nearly fluid jelly with 16 to 20 parts of water. They are characterised by the presence of vegetable particles which are rendered more distinct by staining with iodine. They yield a precipitate with alcohol, which does not dissolve readily in hot water. Fehling's solution is not reduced, unless the liquid has previously been heated with dilute acid. In practice the formation of rust on the steel may be prevented by adding sufficient alkali. Glue solutions for drilling purposes are prepared by dissolving 40 parts of glue in 50 parts of water and 10 parts of potassium hydroxide solution (50° B., sp. gr. 1.53). Glue is precipitated almost quantitatively by tannin, and contains about 15% of nitrogen. The other group of drilling oil substitutes consists of mixtures of the above-mentioned preparations with mineral oil or tar oil, as, for example, a mixture of 80 parts of sulphite lye, 5 parts of potassium hydroxide solution (40° B., sp. gr. 1.38), and 15 parts of tar oil or mineral oil. They should be tested as to their emulsibility with water and rust-preventing properties. For the analysis of these products 10 grms. is dissolved in 100 c.c. of petroleum spirit, and repeatedly shaken with alcohol. The alcoholic extracts, which will contain any emulsifying soaps present, are evaporated, and the residue dried and weighed. If ammonium soaps are present the ammonia will be driven off during the evaporation, and the residue will consist only of the fatty acids, etc., of the soap. The residue is decomposed with dilute acid and the separated acids are tested for fatty acids, rosin acids, and naphthenic acids. To detect the last-named, the acids are converted into copper salts and treated with petroleum spirit, which dissolves copper naphthenate forming a green solution. Naphthenic acids may be distinguished from fatty acids by the greater solubility of the magnesium salts in water. They have also a much higher sp. gr. (e.g., 0.998 as compared with 0.898 to 0.920 at 20° C.). Another characteristic of naphthenic acids is their ready formation of sparingly soluble "formolites." The acid under examination is mixed with an equal vol. of strong sulphuric acid and shaken with about one half vol. of 40% formaldehyde. After standing for about 15 mins. the liquid is diluted with water and treated with ether, which dissolves the decomposition products of oleic acid, etc., leaving an insoluble precipitate of the naphthenic acid compound. Finally the preparations are tested for volatile constituents such as alcohol, petroleum spirit, and ammonia.

—C. A. M.

Action of coal gas on plants. Wehmer. See XVI.

PATENTS.

Coal or the like; Apparatus for washing — and for separating it from its impurities. The Grange Iron Co., Ltd., and H. P. Hoyle, Durham. Eng. Pat. 119,835, 22.5.18. (Appl. 8539/18.) Addition to 15,827 of 1915 (this J., 1916, 1209).

In coal-washing apparatus of the type described in the principal patent, the coal is fed from a hopper

on to an inclined perforated plate in a tank, and the water is circulated by a parallel plate below, which is pivoted at one end, and reciprocated at the other by an eccentric and rod. The reciprocating plate is provided with flap valves which open only on the downward stroke. At the lower end of the perforated plate, pockets for collecting dirt are provided, which are closed by pivoted and counter-weighted doors at the bottom. The doors are opened by the weight of the material, and are connected with dash-pots to control their movements. The perforated plate is kept free from clogging by a scraper which is slowly reciprocated over it by means of an eccentric and pawl and ratchet. The washing water overflows into a settling tank provided with vertical baffle-plates having openings which are out of line with one another. The slurry settling in this tank is delivered by a conveyor on to an elevator which receives the washed coal from the perforated plate.—W. F. F.

Combustible gases; Device for producing —. Chinese-American Co., Boston, Mass., Assignees of W. B. S. Whaley, Malden, Mass., U.S.A. Eng. Pat. 111,102, 13.10.17. (Appl. 14,850/17.) Int. Conv., 19.10.16.

"CRUDE gas, e.g., coal gas, enters a separator chamber in which solid impurities and heavier coal distillation products are retained; the gas and lighter liquid products go forward into the distributing box of a chamber containing a large number of parallel jet pipes. The gas passes down through these pipes at high velocity, and on emerging, impinges on a metal partition heated from underneath by the exhaust gases from an internal combustion engine which afterwards pass into the air. The vapours in the coal gas are thereby completely gasified or "cracked." The hot gases pass up round the pipes (thereby heating the incoming gas) to the outlet of the chamber, and after cooling are ready for use in a gas engine without further purification. The device may also be used as a carburettor, in which case, oil is run into the space above the hot plate and air forced through the jet tubes. The air in bubbling through the heated oil becomes carburetted.—T. F. E. R.

Gas-producers. S. Glover, St. Helens, J. West, Southport, and West's Gas Improvement Co., Ltd., Manchester. Eng. Pat. 119,723, 23.10.17. (Appl. 15,396/17.)

The producer gas is taken off directly from the hot zone, by ports leading into an annular chamber wherein dust is deposited, and the gas then passes to the gas main. The ash is discharged at the bottom by the action of a rotating inverted cone having on its interior a projecting spiral rib. The ash falls on to a table placed at such a distance from the bottom of the cone as to prevent the producer emptying itself; a rotating vane continually discharges some ash from this table. The joint between the revolving cone and the producer is water-sealed. By a suitable arrangement of pipes at this point, steam or other gases can be admitted. Air is admitted to the producer at the lower end of the cone.—T. F. E. R.

Gas for internal combustion engines and for other purposes; Method and means for electrically producing —. T. McClelland, Glasgow. Eng. Pat. 119,885, 24.9.17. (Appl. 13,697/17.)

CARBON, similar to arc-lamp carbon, in granules about pea size, is loosely packed in separate parallel grooves, or one sinuous groove, in the bottom of a porcelain vessel. The carbon is covered with water alone, or water containing

acid or alkali. Electric conductors pass through the gas-tight cover of the porcelain vessel and make contact with the rows of carbon granules. By passing a suitable current through the granules an explosive gas is evolved partly by electrolytic action and partly by the smothered arcing action between the granules. An opening is provided for withdrawing this gas for use in a gas engine. As an alternative to the grooves, the carbon may be contained in perforated porcelain tubes closed at the ends by carbon conducting blocks of lower electrical resistance than the granules.—T. F. E. R.

Gas; Apparatus for making — J. U. McDonald, La Grande, Oreg., Assignor to American Gas and Incinerator Co., Tacoma, Wash. U.S. Pat. 1,278,180, 10.9.18. Appl., 22.11.16.

The apparatus comprises a vertical retort above which is a charge chamber closed top and bottom by gas-tight valves. The charge chamber is filled with the material to be carbonised from a superposed hopper by opening the top valve. When full this valve is shut and the bottom one opened, and the charge is fed into the retort at any desired rate through a chamber containing an endless screw. The residue is removed from the bottom of the retort by a horizontal endless screw. The gas is taken off at the top of the retort, below the feed chamber. Pressure-equalising pipes connect the bottom of the retort with the bottom of the charge chamber, and the top of this chamber with the hydraulic main.—T. F. E. R.

Gas producers; Method for the control of — A. Riedel, Ger. Pat. 308,259, 4.1.16.

In those parts of the producer in which a low temperature is desirable, a spray of water is introduced along with the blast and steam. The fineness of the spray is controlled by an arrangement of jets. In any cross-section of the producer the centre and outer portions are kept cool. Between these there is a region of higher temperature. By adjustment of the jets it is possible to obtain a uniform rate of gas production in any cross-section despite differences of temperature which exist.

—J. S. G. T.

Cracked oils; Purification of — A. E. Dunstan, Sunbury-on-Thames, Eng. Pat. 119,751, 28.11.17. (Appl. 17,613/17.)

OLEFINS and diolefines, which impart a yellow colour and objectionable odour to petroleum cracked by the usual methods, are removed by slowly distilling the cracked oil in the presence of about 1% of an anhydrous chloride (e.g., anhydrous aluminium chloride). To render it more effective, the chloride may be applied dissolved in an anhydrous solvent (e.g., absolute alcohol), or mixed with a dry inert material; the mixture may also be stirred during distillation.—L. A. C.

Heavy fuel oils [mixtures of heavy oil with pitch]; Treatment of — preparatory to burning. J. W. Westwood, Birmingham, Eng. Pat. 119,977, 9.2.18. (Appl. 2372/18.)

PITCH is melted in a tank heated by steam or superheated water, and is heated to a temperature below the flash point of the oil with which it is to be mixed. It is then forced into heavy oil contained in another tank heated by similar means. The mixture is pumped around a system of pipes connected with the burners, any excess oil being returned through a return pipe to the mixing tank. Agitation of the oil and pitch in the mixing tank is effected by feeding in the pitch and excess mixture from the burners through a pair of perforated

pipe systems or spargers so disposed that the issuing streams effectively mix and agitate the contents of the tank.—L. A. C.

Charging vertical retorts or arcs; Apparatus for —. Apparatus for discharging coke or the like. J. Pieters, Paris, Eng. Pats. 113,435 and 113,436, 22.1.18. (Appls. 1272 and 1273/18.) Int. Conv., 10.2 and 16.2.17.

Burning solid fuel; Process of — F. Thuman, London, From O. B. Evans, Lansdowne, Pa., U.S.A. Eng. Pat. 120,011, 20.6.18. Appl. 10,206/18. SEE U.S. Pat. 1,267,646 of 1918; this J., 1918, 499 A.

PATENTS.

Wood; Carbonisation of — L. E. Tissier, Batna, Algeria, Eng. Pat. 110,360, 8.10.17. (Appl. 14,511/17.) Int. Conv., 6.10.16. Addition to 105,915 (this J., 1918, 184 A).

Wood contained in a kiln is carbonised by the exhaust gases of internal combustion engines, e.g., those worked with poor gas. The exhaust gases are passed into the kiln through a grating at the bottom, and the gaseous products from the wood, including tar, are withdrawn at the top through a removable sheet metal hood provided with a water seal, and then passed into a condenser. The charcoal is withdrawn through a door at the side and quenched in a pit immediately below.

—W. F. F.

Carbonisable materials; Distillation of — A. L. Pearse, London, Eng. Pat. 119,700, 11.10.17. (Appl. 14,725/17.)

CARBONACEOUS material such as coal, lignite, oil shale, or the like, is fed continuously from air-tight hoppers into a series of vertical retorts, and the solid residue is continuously withdrawn at the bottom. The retorts are heated by superposed horizontal flues in the dividing walls, each flue being provided with a gas burner at one end which can be separately regulated. The air supply is preheated by passing it through passages in the walls at the bottom, and the carbonised material is thereby cooled. The horizontal flues are connected by short vertical passages which are provided with dampers and increase in size with their distance from the burner. The lowest horizontal flue is connected to a discharge stack, so that the hot gases move horizontally along their respective flues and also downwards through the lower flues to the stack. Cold air may also be supplied to each flue. The retorts are thus heated in zones the temperature of which increases progressively towards the bottom. Discharge conduits are provided for the gases at two different levels, and are formed by increasing the width of the retort in steps downwards at those places, and allowing the end wall of the upper narrower zone to project

downwards into the lower zone, thus forming a vertical discharge conduit which is not subject to choking. In distilling coal, the upper zone is maintained at 900°–1000° F. (480°–540° C.), the middle zone at 1350° F. (730° C.), and the lower zone at a higher temperature. Gas from the upper and middle zones, containing benzene and toluene, is withdrawn through the upper conduit, and gas from the lower zone consisting of hydrogen, carbon monoxide and dioxide, and ammonia, is withdrawn from the lower conduit.—W. F. F.

Retorts for distilling, carbonising, roasting, and the like, of coal, carbonaceous and other materials. A. Bradley, London. Eng. Pat. 119,911, 18.10.17. (Appl. 15,134/17.)

HORIZONTAL or slightly inclined retorts are arranged in superposed pairs and are surrounded by heating flues and separately heated by regulated gas burners. An endless chain conveyor travels through each pair of retorts, and the fuel or ore is fed from separate hoppers at opposite ends of the two retorts and discharged at the other end of each retort. A band conveyor may be used for finely divided material not liable to cake during heating. The conveyor passes through a closely fitting slot at the entrance to the retort to remove adhering material and prevent loss of heat. The material is discharged from the conveyor by a fixed V-shaped plate into lateral shoots. For a material which cakes during heating, a conveyor carrying cup-shaped scoops may be used. The apparatus is applicable for carbonising coal, shale, peat, and wood, and for roasting minerals or the like.

—W. F. F.

Incandescence bodies; Preparation of — composed of a conductor embedded in rare earths. J. Frank Rahtjen, Berlin-Schöneberg. Ger. Pat. 308,036, 30.11.13.

A HELICAL conductor is covered with fibre which is then saturated with salts of the rare earths. The incandescence body so obtained is then burnt off, covered with shellac or similar substance, shaped, and hardened in a neutral atmosphere or *in vacuo*.—J. S. G. T.

Charging and discharging of retorts for the distillation of coal, shale, or the like. J. Robertson, Glasgow. Eng. Pat. 119,715, 22.10.17. (Appl. 15,284/17.)

III.—TAR AND TAR PRODUCTS.

Coal-tar industry; Methods of analysis used in the —. II. Distilled tars and pitches. J. M. Weiss. J. Ind. Eng. Chem., 1918, 10, 817–823.

WATER, sp. gr., matter insoluble in benzene, and viscosity of distilled tar are determined by the methods mentioned for the analysis of crude tar (this J., 1918, 648A). Consistence is determined by the Schutte penetrometer or by the float apparatus, and the distillation test is made under definite conditions in an apparatus of standard dimensions. In the case of pitch, the sp. gr. may be determined by the methods mentioned and also by the suspended cube (in water) method. The melting point is determined by noting the temperature at which a cube of the pitch drops from a metal hook when suspended in water, and the melting point in air is determined in a similar way. The evaporation test consists in heating 10 grms. of the pitch in a nickel basin for 7 hrs. at 163° C. and noting the loss in weight. The

sliding test is made by placing a cube of the pitch in a groove in a plate inclined at 30° and heated at 40° C., the extent of the flow being noted after 7 hrs.—W. P. S.

Hydroxyazo-compounds; Electrolytic reduction of —. E. Puxeddu. Gaz. Chim. Ital., 1918, 48, II., 27–30.

In alcoholic solution containing hydrochloric acid, *p*-hydroxyazobenzene undergoes electrolytic reduction to *p*-aminophenol, whereas, dissolved in sulphuric and acetic acids, it gives no definite result.—T. R. P.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool fibres; Influence of humidity upon the strength and elasticity of —. J. I. Hardy. J. Agric. Res., 1918, 14, 285–295.

The breaking strength of wool fibres was determined under controlled conditions of temperature and moisture by means of Reeser and Mackenzie's fibre-testing machine (Matthews, "Textile Fibres," 1913, p. 254). The tests were made in a special room, the temperature of which was controlled by a thermograph electrically connected with overhead lamps, whilst the humidity was controlled by means of a hydrograph connected with atomisers distributing a fine spray of water into a large tank. It was found that the wide variations in the size of individual fibres caused the determination of the breaking-strength to be an unsatisfactory method of measuring the strength of wool. Owing to irregularity in the shape of the fibres, microscopical measurement of the diameter gave inaccurate results, but rapid and accurate measurements were made by means of a micrometer caliper substituted for the lower jaw of the testing machine. The tensile strength (ratio of breaking strength to area of cross-section) was calculated from the diameter of the fibre as measured at the smallest point. Comparison of the tensile strength at five relative degrees of humidity (40, 50, 60, 70, and 80%) showed a decrease in strength with the increase in the humidity, and *vice versa*. The percentage elasticity of wool fibres increased with the rise in the humidity. For example the average elasticity of four samples of different kinds of wool fibres increased from 27.81 at a relative humidity of 40% to 39.08 at a humidity of 80%.—C. A. M.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Bleaching and washing materials; Determination of loss of oxygen during the use of oxygen-yielding —. A. Grün and J. Jungmann. Chem.-Zeit., 1918, 42, 473—475.

THE method described consists in heating a known weight of fabric with a definite quantity of the bleaching agent in a flask under reduced pressure. The flask is connected through a condenser with a gas burette, in which any gases given off during the heating are collected. Subsequent analysis of the gases gives the quantity of oxygen evolved from the bleaching agent and not combined with the fabric, etc. The quantity of nitrogen found in the gases is taken as a measure of the air present in the apparatus and an allowance is made for the oxygen derived from this source. Results of experiments with perborates show that from 60 to 80% of the active oxygen escapes in the gaseous form, but if soap is also present the loss is under 12%. The greater part of the active oxygen is absorbed by the oxidisable constituents of the soap.—W. P. S.

Cotton fibre; Dyeing of — with basic dyes. R. Haller. Kolloid Zeits., 1918, 23, 100—106.

THE mechanism of dyeing cotton with basic dyes is shown to be the following in the case of Methylene

Blue. On immersing the fabric in a tannin solution, this by virtue of its highly disperse state penetrates into the interstices, and when the tannin-charged fabric is placed in a solution of tartar emetic this substance as a molecular disperse solution penetrates very rapidly and forms in the interstices an insoluble antimony-tannin compound. When now the fabric is placed in the Methylene Blue bath this substance, being also highly disperse, penetrates and forms a complex lake, tannin-antimony-Methylene Blue, which is fixed in the fibre. A similar course is followed when aluminium sulphate is used instead of tartar emetic, but in this case the tannin-aluminium compound is soluble and consequently the colours are not so fast as in the former case.—J. F. S.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Cottrell processes in the sulphuric acid industry. A. A. Heimrod and H. D. Egbert. Chem. and Met. Eng., 1918, 19, 309—314.

THE Cottrell process is used in the manufacture of sulphuric acid for cleansing the hot gases as they leave the pyrites burners, and for removing the mist of acid carried in the gases from concentrators and absorption towers. In the former case the temperature of the gases and character of the suspended matter are governing factors, and at temperatures of 1000° F. (540° C.) and over, and for the removal of dust rather than fume, precipitators of the plate type are preferable in which the gases pass horizontally between collecting and discharge electrodes. With gases cooled to about 600° F. (320° C.) and for the removal of fume, the pipe type of precipitator is preferable. In a Wisconsin plant for roasting zinc ore, 17,500 cub. ft. of gas per minute is cleansed at about 500° F. (260° C.) by an installation of two units, each containing 36 steel pipes as collecting electrodes, 12 in. in diameter and 15 ft. high, with discharge electrodes in the form of chains arranged axially. The electrical equipment consists of a 200 to 65/70/75/80/85000 volt transformer, and the power consumption is about 18 kilowatts; 7600 lb. of

material containing 22% zinc and 30% sulphur is collected every 24 hours. In a precipitator at Baltimore working at 1100°–1400° F. (590°–760° C.), 17,500 cub. ft. of gas per minute at 1100° F. (590° C.) is treated, and 900 to 1200 lb. of dust per day is obtained from the roasting of 40 to 50 tons of pyrites. The installation is made in two sections, each of which may be shut off by dampers. The electrodes are heavy steel plates, suitably reinforced, suspended, and insulated, and a voltage of about 50,000 volts is used, the power consumed being not over 2 kilowatts. For the removal of acid mist from concentrator gases, the pipe type of precipitator is employed. Precipitators of this type are described, in one of which 3000 cub. ft. of gas per minute at 135° F. (57° C.) is treated from three concentrators of the tower type yielding 50 tons of acid of 66° B. (sp. gr. 1.84) per 24 hours, and 3000 lb. of acid of 18° B. (sp. gr. 1.14) is recovered per 24 hours from the mist. A potential of 75,000 volts is employed, with a power consumption of 3½ kilowatts. Another unit, similarly equipped electrically, of 12 pipes each 12 in. by 15 ft., treats 2500 cub. ft. of gas per minute at 200° F. (93° C.) from two tower concentrators producing 40 tons of acid of 66° B. (sp. gr. 1.84) per 24 hours, and 3500 lb. of acid of 33° B. (sp. gr. 1.296) is recovered. One of the largest installations cleanses 30,000 cub. ft. of gas at 180° F. (82° C.) per minute from 22 concentrators of the cascade type, each producing 10 tons of 66° B. acid per 24 hours. Four units, each of 12 pipes, 12 in. by 15 ft., are employed, and 25 tons of 45° B. acid (sp. gr. 1.45) is recovered per 24 hours. The high-potential parts of precipitators for collecting acid mist must be provided with insulators having a large safety factor as regards voltage rating, and must be protected from acid fumes. Fans are mostly used to create the necessary draught, but steam jets are used in some cases, though they are not so satisfactory.—B. N.

Sulphur in pyrites: Source of error in the determination of —. O. Binder. *Chem.-Zeit.*, 1918, 42, 503.

To ensure thorough mixing of the sodium carbonate and potassium nitrate in preparing a stock of fusion mixture, it is recommended that the sodium carbonate be suitably coloured and the mixing then continued until the colour of the whole mixture is uniform.—W. P. S.

I. Hydrochloric acid; Detection and separation of — in presence of bromic and iodic acids.

II. Bromic and iodic acids; Detection and quantitative determination of — in presence of hydrochloric, hydrobromic, and hydriodic acids. A. Purgotti. *Gaz. Chim. Ital.*, 1918, 48, II, 63–66.

The methods described are based on the property possessed by potassium or sodium hydroxide of attacking silver bromate and iodate, whereas silver chloride, bromide, and iodide remain unchanged. The solution to be examined is treated with silver nitrate solution in presence of nitric acid, the precipitate being collected and washed and then digested for some minutes in the cold with the alkali hydroxide solution; silver bromate and iodate are thus transformed into the corresponding soluble alkali salts. The liquid is filtered and the precipitate thoroughly washed, and tested for chloride, bromide, and iodide in the usual way. To test the filtrate for bromate and iodate ions, it is acidified with excess of hydrochloric acid and treated in a test-tube with one or two c.c. of carbon bisulphide, sulphurous acid solution being then carefully added, drop by drop, and the whole vigorously shaken. In presence of bromic acid the carbon bisulphide

becomes yellow or orange-yellow, and in that of iodic acid, violet. If both bromic and iodic acids are present, careful addition of the sulphurous acid reveals first the yellow colour of the bromine and afterwards the violet colour of the iodine. The presence in the original silver precipitate of salts of the cyanogen acids does not affect the reaction, since silver thiocyanate and ferrocyanide are not attacked by cold alkali hydroxide, whilst the cyanide is slightly attacked and the ferricyanide decomposed; when cyanide and ferricyanide are present, rather more sulphurous acid is added. The determination of bromic and iodic acids in presence of hydrobromic and hydriodic acids may be effected by employing the means of separation described above, the alkaline solution containing sodium or potassium bromate and iodate being then reduced with either zinc dust, or aluminium or Devarda's alloy (Cu 50, Al 45, Zn 5), and the bromide and iodide precipitated with silver nitrate in acid solution. If cyanogen derivatives are present, they must be removed, the procedure being as follows: the silver precipitate is calcined, the residue treated with dilute sulphuric acid and zinc, and the solution reprecipitated with silver nitrate; the precipitate then contains only bromide and iodide.—T. H. P.

Selenious and selenic acids; Volumetric determination of —. L. Moser and W. Prinz. *Z. anal. Chem.*, 1918, 57, 277–305.

The most accurate results in the determination of selenious acid are obtained when the substance is distilled with hydrochloric acid and an excess of potassium iodide (four times the quantity required by theory), and the liberated iodine then titrated both in the receiver and in the residue. The indirect iodometric method described by Gooch and Pierce (*Z. anorg. Chem.*, 1896, 11, 249), in which the selenious acid is heated with a definite and known excess of potassium iodide in the presence of potassium hydrogen arsenate and sulphuric acid, and the arsenious acid formed then titrated with iodine solution after neutralisation, also gives accurate results if carried out as a distillation process. In the oxidation of selenious acid by permanganate in alkaline solution there is always some loss of oxygen when the hot mixture is acidified previous to the titration of the excess of permanganate, and the results obtained are, therefore, inaccurate. There is formation of hydrogen selenide when selenious acid is titrated with titanium trichloride solution and this method is, consequently, unsatisfactory. The best method for the determination of selenic acid consists in reduction with hydriodic acid. The selenic acid solution (100 c.c.) is treated with 10 c.c. of concentrated hydrochloric acid and an excess of potassium iodide (5 grms. for each 0.1 gm. of selenium), the mixture distilled in a current of carbon dioxide, and the iodine titrated in the receiver and also in the residue.—W. P. S.

Ammonia-oxidation and similar reactions; Starting and stability phenomena of —. F. G. Liljenroth. *Chem. and Met. Eng.*, 1918, 19, 287–293.

It has been shown by the "conversion curves," giving the percentages of ammonia oxidised at various temperatures, and the "heat of reaction line," which gives the temperature of the gauze or catalyst for various percentages of conversion, that the latter line is straight and cuts the conversion curve at two points, one only of which is stable. This position is the one where the line cuts the curve from below. It is shown that there is a particular ignition temperature to which the mixture must be heated to start the reaction. It is of

importance to keep the composition and velocity of the gas constant, in order to keep the reactions stable, and in the presence of catalyst-poisons a higher working temperature must be employed either by the use of a heat exchanger or the supply of additional heat. The stability of the reaction is probably increased with increase in the percentage of ammonia in the mixture used. Increase of gas velocity decreases the conversion and the stability, and increase of thickness or number of gauzes has the same effect, though the introduction of a heat exchanger may stabilise the reaction in the former case with an increased output. It is suggested, however, that it may be possible to use a low-grade catalyst for the first gauze and a platinum one for completing the oxidation, and that, by obtaining conversion curves for different gas strengths and velocities for ammonia-air and ammonia-oxygen mixtures, it may be possible to adjust or design a burner for a maximum commercial efficiency.—B. N.

Potassium chloride; Heat technology applied to solution and cooling in the preparation of — [from crude potassium salts]. Krull. Kali, 1917, 11, 307–316. Z. angew. Chem., 1918, 31, Ref., 303.

THE separation of potassium chloride from crude potassium salts, depending upon the different solubilities of potassium chloride and sodium chloride at different temperatures, is essentially a problem of applying and extracting heat. According to the constitution of the crude salts, extraction is effected at 90°–130° C., and the solution is cooled to 15°–25° C. Enclosed steam is usually employed in the extraction process, the liquor being warmed to 70° C. in preheaters, and then heated to 90°–115° C. in the extraction vessels. Low-pressure exhaust steam is used. In cooling the liquors, the main object is to produce a high yield of well-defined crystals. Heat may or may not be recovered during the process; preferably, the liquor is cooled to a low temperature without the recovery of heat. Salts precipitated at lower temperatures are somewhat contaminated with sulphate, but these may be profitably employed in the manufacture of sulphates; on the other hand, the quality of the liquor is improved for use again in the extraction process by the removal of sulphates. The cooling boxes formerly employed yielded a product excelled by no other method; on the other hand, they possessed great disadvantages in their low output and the necessity for removing the product by hand. Cooling by stages only partly remedied this defect.—L. A. C.

Nitrites and hydrogen peroxide; Determination of small quantities of —, separate or together. [Estimation of sulphur in thiocyanates.] A. Quartaroli. Gaz. Chim. Ital., 1918, 48, 1, 102–111.

THE bromine water usually employed for the oxidation of the sulphur present in thiocyanates to sulphuric acid, to be estimated as barium sulphate, may be conveniently replaced by nitric acid and sodium nitrite; to 5 c.c. of thiocyanate solution mixed with 50 c.c. of water was added 2 c.c. of concentrated nitric acid, the liquid being heated over a small flame, and a solution of 1 gm. of sodium nitrite in 20 c.c. added, drop by drop and with stirring, before the temperature reached about 60° C.; the solution was then heated to boiling and barium chloride added immediately. Percentage of thiocyanate thus found in solution was 6.15, whilst with bromine the result was 6.18.

The following reagent gives a blood-red coloration with a nitrite, the reaction being capable of

detecting about 1 part of nitrite per 200,000,000 of solution; to 100 c.c. of the above potassium thiocyanate solution are added 0.5 gm. of crystallised ferrous sulphate and 2 c.c. of pure, colourless nitric acid diluted with an equal volume of water, the liquid being then stirred until the ferrous sulphate is completely dissolved. Two c.c. of the reagent is added to 25 c.c. of the solution under examination. A similar reaction, though less intense, is given by hydrogen peroxide (1:30,000,000), potassium persulphate, and probably other compounds of the type of hydrogen peroxide, but not by chlorates or perchlorates. With hydrogen peroxide, the maximum coloration is reached almost instantaneously, but with nitrites, slowly and with characteristic striation. If the reaction is positive and the coloration does not change at all when the liquid is heated rapidly to boiling with hydrochloric acid and urea, hydrogen peroxide is present, but no nitrite, and the peroxide may easily be determined colorimetrically. If the reaction is positive and the liquid becomes paler but not colourless when boiled with hydrochloric acid and urea, both nitrous acid and hydrogen peroxide are present, the former in excess. If the reaction is positive and the coloration disappears or, rather, becomes similar to that obtained with distilled water, on boiling with hydrochloric acid and urea, only nitrous acid or excess of this and a small proportion of peroxide may be present.—T. H. P.

Sulphites, thiosulphates, and polythionates; Studies on —. A. Sander. Z. angew. Chem., 1918, 31, 197.

IN connection with his work on the quantitative determination of sulphites, thiosulphates, and polythionates (this J., 1915, 225, 277; 1916, 307, 421), the author has studied the action of these substances on mercuric chloride. By the interaction of mercuric chloride with alkali thiosulphates and polythionates, very unstable mercury thiosulphates and polythionates are formed, which immediately break down into mercuric sulphide and free sulphuric acid (together with free sulphur in the case of tetra- or pentathionates). Alkali sulphites and bisulphites, on the other hand, form with mercuric chloride stable complex compounds, salts of the disulphonic acid, $\text{Hg}(\text{SO}_3)_2$, and of the chlorosulphonic acid, HgClSO_3H . The quantitative analytical processes worked out by the author depend upon this difference in behaviour towards mercuric chloride.—E. H. R.

Phosphates; Behaviour of — at the anode. F. Fichter and J. Müller. Helv. Chim. Acta, 1918, 1, 297–305.

BY the anodic oxidation of a 2M solution of dipotassium hydrogen orthophosphate containing 2N potassium fluoride and 0.32 gm. of potassium chromate per litre, the potassium salts of monoperphosphoric acid ($\text{K}_2\text{P}_2\text{O}_7$) and perphosphoric acid ($\text{K}_2\text{P}_2\text{O}_8$) have been obtained. The electrolytic oxidation is most efficiently carried out at 5° C. between platinum electrodes in an undivided cell and with a current density of 0.01 amp. per sq. cm.—J. F. S.

Hypophosphates; Preparation of —. R. G. Van Name and W. J. Huff. Amer. J. Sci., 1918, 46, 587–590.

HYPHOPHOSPHATES are best prepared by suspending a number of sticks of phosphorus cast round glass rods in a stout glass jar containing a litre of water and 250 grms. of sodium carbonate, which need not be dissolved. The sticks of phosphorus should be about $3\frac{1}{2}$ in. long and $\frac{3}{4}$ in. diameter, and should protrude about $\frac{1}{2}$ in. from the solution. The whole

is then placed in a cool position and left to react until a few drops of the solution just turns Congo red. The phosphorus is then removed and placed in a similar solution. The product, sodium hydrogen hypophosphate, is found in part as a crystalline precipitate at the bottom of the jar, whilst the remainder is obtained by concentrating the solution. It is recrystallised to remove the accompanying phosphates and phosphites. The best temperature to carry out the reaction is $10^{\circ}\text{C}.$ – $15^{\circ}\text{C}.$, and the yield is 10%–16% of the theoretical value.

—J. F. S.

Iron disulphide (FeS_2); Formation of — by a wet method. V. Rodt. Mitt. K. Materialprüf., 1918, 36, 93–107.

THE iron trisulphide formed as the first product of the interaction of hydrogen sulphide and iron hydroxide, readily becomes partially insoluble in hydrochloric acid, as for example, when the reaction is carried out at a higher temperature. The insoluble substance has the composition FeS_3 , sp. gr. 4.58 at $18^{\circ}/4^{\circ}\text{C}.$, and is formed in accordance with the equation $\text{Fe}_2\text{S}_3 \rightarrow \text{FeS}_2 + \text{FeS}$. It may also be produced by the addition of sulphur to iron sulphide, in the absence of substances with an alkaline reaction, which also interfere with its formation from iron trisulphide. It is probably formed in this way in soils containing iron hydroxide and putrescent matter, but free from alkaline-earth carbonates. By boiling solutions of iron with alkali polysulphides it may be found possible to separate iron quantitatively in the form of iron disulphide. (See also Alkali Inspector's Reports, this J., 1912, 717; 1913, 787; 1914, 861; also J. Chem. Soc., Dec., 1918.)—C. A. M.

Tungsten compounds; Analysis of — by volatilisation in a current of carbon tetrachloride vapour. P. Jannasch and R. Leiste. J. prakt. Chem., 1918, 97, 141–153.

THE method depends on the formation of a mixture of volatile chlorine derivatives of tungsten when tungstic acid or a tungstate is heated in a current of carbon dioxide saturated with carbon tetrachloride vapour. The volatilised compounds are decomposed by dilute acids and the tungstic acid is precipitated. A temperature below red heat is required for the volatilisation, which takes about 1 hr. for completion. The method may be used for the determination of tungsten in scheelite and wolframite.—W. P. S.

Molybdenum compounds; Analysis of — by volatilisation in a current of carbon tetrachloride vapour. P. Jannasch and O. Laubi. J. prakt. Chem., 1918, 97, 154–181.

THE substance, such as molybdic acid, molybdates, molybdenum ores, etc., is heated in a current of carbon dioxide saturated with carbon tetrachloride vapour; the molybdic acid volatilises, and is collected in a receiver, then evaporated with nitric acid, ignited, and weighed. To determine molybdenum, 0.4 gm. of the sample is heated at 430° – $630^{\circ}\text{C}.$ in the carbon dioxide-carbon tetrachloride vapour and the volatilised substances collected in a suitable receiver; a trace of substance may remain unvolatilised and this may be heated with hydrochloric acid, the solution filtered, and the filtrate added to the contents of the receiver, which are then evaporated. After silica has been separated in the usual way, the solution is heated with an excess of ammonia, the ferric hydroxide collected on a filter, and the filtrate evaporated to dryness with the addition of *aqua regia*; the residue of molybdic acid thus obtained still contains traces of silica and is once more volatilised in a current of carbon tetrachloride.—W. P. S.

Carbides of the rare earths of the cerium group. A. Damiens. Ann. Chim., 1918, 10, 137–183.

THE carbides of the cerium group of metals when decomposed by water give off a gas which is, in all cases, a mixture of hydrogen, saturated hydrocarbons consisting of ethane, propane, and isobutane but no methane, ethylene and its homologues, and acetylene and its homologues. The different constituents of this gaseous mixture, whilst invariably present, vary in their relative proportions according to the velocity of the reaction, which is dependent on the physical state of the carbide. The metallic hydroxides produced are those corresponding to the sesquioxides. Cerous hydroxide was isolated in the pure state as a white compound, which fixes oxygen in the cold with the evolution of heat and the formation of ceric hydroxide.

—W. G.

Mesothorium to thorium; Ratio of —. H. N. McCoy and L. M. Henderson. J. Amer. Chem. Soc., 1918, 40, 1316–1326.

THE term "1 mgrm. of mesothorium" is applied to the quantity of $\text{Ms}_1 + \text{Ms}_2$ in equilibrium which has a γ -ray activity equal to that of 1 mgrm. of radium in equilibrium with its first four products. The γ -activity was measured through 2.03 mm. of lead+1.32 mm. of brass. The results of the research show that "1 mgrm. of mesothorium" is in equilibrium with 19 kilos. of thorium in minerals, or 1 mgrm. of thorium is in equilibrium with 0.524×10^{-4} mgrm. of mesothorium. This last ratio is only one sixth as great as the ratio of radium to uranium, namely 3.23×10^{-4} mgrm. of radium per 1 gm. of uranium. (See further J. Chem. Soc., Dec., 1918.)—F. S.

Silicic acid gels. H. N. Holmes. J. Phys. Chem., 1918, 22, 510–519.

INSTRUCTIONS are given for preparing silicic acid gels from water-glass and a long series of acids. In addition the concentrations and quantities of the various acids necessary to produce gels which will set in a definite period are also determined. (See J. Chem. Soc., Dec., 1918.)—J. F. S.

PATENTS.

Sulphuric acid; Manufacture of —. A. B. Foster, Washington, D.C. U.S. Pat. 1,277,896, 3.9.18. Appl., 23.7.14.

SULPHUR-BEARING material is burned in a limited supply of air, and the gas—on its way to and from the Glover tower—is subjected to the action of atomised chamber acid which is injected by means of air blasts, and in the direction of the gas flow, at a number of points along the connecting flues, and then removed. The chamber gases are similarly treated.—W. E. F. P.

Sodium and aluminium hypochlorites; Process for the manufacture of —. E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 119,261, 22.8.17. (Appl. 12,058/17.)

A MIXTURE of bauxite (or other suitable aluminous material), calcium hydroxide, sodium chloride, and carbon is heated to redness in the presence of arsenic trioxide, whereby sodium aluminate, calcium carbonate, arsenic trichloride, hydrogen, and carbon dioxide are produced. The product is lixiviated with water, and one-half of the solution

obtained is treated with carbon dioxide to precipitate aluminium hydroxide which, after separation, is suspended in the remaining half of the liquid. This mixture is treated with chlorine until the suspended aluminium hydroxide is dissolved, after which the solution is first neutralised with sodium hydroxide (to precipitate sodium chloride, which is removed) and then treated with a further quantity of this reagent to produce a solution of sodium hypochlorite and precipitate the whole of the aluminium as hydroxide. The latter precipitate is separated, mixed with water, and treated with chlorine to produce a solution of aluminium hypochlorite.—W. E. F. P.

Nitre cake; Method for the utilisation of — [in the production of hydrochloric and nitric acids]. J. Grossmann, Manchester. Eng. Pat. 119,290, 28.9.17. (Appl. 13,975/17.)

In the production of nitric and hydrochloric acids by heating sodium nitrate and sodium chloride with nitre cake to about 250° C. and 450° C. respectively, the finely powdered materials are mixed with coke or other carbonaceous material to render the residual salt-cake friable and easily removable. The reducing action of the coke is minimised by regulating the proportion and size of the fragments employed.—W. E. F. P.

Manganese dioxide; Process of separating — from ore containing the same. Separator for separating manganese dioxide from ores containing the same. L. E. Sowers and P. S. Phillips, Livermore, Cal. U.S. Pats. (a) 1,277,144 and (a) 1,277,145, 27.8.18. Appls. 12.9 and 30.10.17.

(a) The dry, powdered ore is fed into a vessel in which an upward stream of water is maintained, and the lighter particles are removed by peripheral overflow. (a) The apparatus consists of a funnel-shaped vessel provided with a water inlet at the bottom, a peripheral trough at the top, and a central spindle upon which are fixed in succession, from the water level downwards, a conical distributor (partly submerged), a pair of horizontal paddles or vanes, and a helix. The latter is disposed within the funnel stem, and serves to promote uniformity of flow in the upward stream of water.—W. E. F. P.

Alkali-metal-bearing and aluminiferous minerals; Decomposition of refractory —. [Extraction of potash from felspar.] W. H. Swenarton, Montclair, N.J. U.S. Pat. 1,277,773, 3.9.18. Appl. 23.3.12.

A mixture of the material with an "alkali flux" is heated, and the mass is lixiviated with water and the insoluble matter separated. The solution and the residue are then treated separately with sufficient acid to effect decomposition and produce a neutral reaction, whereby alumina and silica are precipitated simultaneously and a solution of a potassium compound obtained in each case.

—W. E. F. P.

[Sodium] cyanide; Crude — and process of producing the same. Electric furnace [for making sodium cyanide]. Process of producing sodium cyanide. H. Freeman, Niagara Falls, Ont., Assignor to American Cyanamid Co., New York. U.S. Pats. (a) 1,277,898, (b) 1,277,899, and (c) 1,277,900, 3.9.18. Appls., 29.11.16, 20.4, and 23.4.18.

(a) An intimate mixture of calcium cyanamide, sodium chloride, and finely divided (chemically active) carbon—the latter having been previously heated to not more than 1000° C.—is heated to a temperature sufficient to produce sodium cyanide.

Crude products obtained by this means, and containing more than 20% and more than 32% by weight of sodium cyanide respectively, are claimed. (b) An electric furnace for making sodium cyanide from "lime nitrogen" (crude calcium cyanamide) and sodium chloride has a hearth of conducting material (which forms the lower electrode) and a funnel-shaped shaft, at the apex of which a small crucible chamber is situated within the hearth. The upper graphite electrode depends within the shaft, is adjustable vertically, and serves to restrict the passage of the charge from the shaft to the crucible chamber. A tap-hole is provided for removing the sodium cyanide produced. (c) A mixture of calcium cyanamide, sodium chloride, and carbon or calcium carbide is fed continuously into the shaft of the furnace described under (a), and through the restricted portion of the mixture within the crucible chamber a current density is maintained sufficient to produce sodium cyanide without causing foaming of the charge.—W. E. F. P.

Sulphur; Separation of — from gases. F. Muh-
lert, Göttingen. Ger. Pat. 306,988, 14.4.16.

The gas, freed from cyanogen and ammonia, is treated with a dilute solution of a copper salt (e.g. copper sulphate), copper sulphide and dilute sulphuric acid being formed. The copper sulphide is separated and heated strongly in a current of air with the production of copper oxide and sulphur dioxide. The copper oxide is dissolved in the dilute acid produced in the first reaction, and the resulting solution used for the treatment of further quantities of gas.—L. A. C.

Hydrogen sulphide; Method for the removal of — from gases. W. Diekmann, jun., Duisburg. Ger. Pat. 308,107, 6.10.16.

The purifying material is used in the form of compact cubical, spherical, laminar, etc. portions, these being formed at a temperature which does not destroy the purifying property of the material. The sulphur is washed out of the purifying material by a solvent or vapour. The advantages claimed for the method are that it is extremely simple, the purifying agent is not removed and does not deteriorate in value, the material can be used until saturated with cyanogen, and the sulphur absorption and recovery take place in the same vessel.

—J. S. G. T.

Liquors containing potassium salts, etc.; Apparatus for cooling and evaporating —. E. Plinkenburg, Mülheim. Ger. Pat. 307,483, 20.9.13.

The liquors are allowed to trickle over hurdles, laths, or the like stacked in a closed apparatus and arranged around one or more shafts closed at the top. The interior of the apparatus is readily accessible from the shafts, and the hurdles, laths, etc., which are removable, can be easily cleaned.

—L. A. C.

Cryolite; Manufacture of — from sodium bisulphate, silica, and fluorspar. Chem. Fabr. Goldschmieden H. Bergius and Co., Goldschmieden. Ger. Pat. 307,525, 23.1.17.

Silicofluoride, produced by decomposition at red heat of fluorspar and silica by means of sodium bisulphate, is absorbed by solid hydrated sodium sulphate, and, after separation of sulphuric acid or sodium bisulphate, the sodium silicofluoride is decomposed by fusing it with crystalline sodium carbonate in the proportion of 1 mol. of sodium silicofluoride to 4 mols. of sodium carbonate, with the production of sodium fluoride, sodium bicarbonate, and silica. The silica is filtered off, and

cryolite precipitated by addition of sodium aluminate to the solution. The following equations represent the reactions which take place: (1) $2\text{CaF}_2 + 4\text{NaHSO}_4 + \text{SiO}_2 = \text{SiF}_4 + 2\text{Na}_2\text{SO}_4 + 2\text{CaSO}_4 + 2\text{H}_2\text{O}$; (2) $3\text{SiF}_4 + 2\text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O} = 2\text{Na}_2\text{SiF}_6 + 2\text{H}_2\text{SO}_4 + \text{SiO}_2$; (3) $\text{Na}_2\text{SiF}_6 + 4\text{Na}_2\text{CO}_3 + 10\text{H}_2\text{O} = 6\text{NaF} + \text{SiO}_2 + 4\text{NaHCO}_3 + 8\text{H}_2\text{O}$; (4) $6\text{NaF} + 4\text{NaHCO}_3 + \text{NaAlO}_2 = (\text{NaF})_3\text{AlF}_3 + 4\text{Na}_2\text{CO}_3 + 2\text{H}_2\text{O}$.

VIII.—GLASS; CERAMICS.

Refractory ware; Production of highly — from non-argillaceous materials, particularly zirconia.
H. Arnold. Chem.-Zeit., 1918, 42, 413—414, 426—428, 439—440.

Pure zirconia melts at about 2600° C., has a coefficient of expansion of 8.4×10^{-7} (quartz, 7×10^{-7}), is highly insensitive to sudden changes in temperature, and has an electrical conductivity of 0.0008 at 1200° C. Zirconia readily dissolves other oxides, and the electrical conductivity at 1200° C. is increased to 0.00255 recip. ohm. by adding 1 mol. Al_2O_3 to 9 mols. ZrO_2 , to 0.0075 at 1000° C. if the alumina is replaced by CoO , and to 0.0358 at 1287° C. if replaced by Fe_2O_3 . Crude zirconia is a good conductor. The author finds that the use of any fluid in pressing zirconia ware is detrimental, and recommends (Ger. Pat. 285,934; U.S. Pat. 1,121,889; this J., 1915, 231) pressing the cold zirconia dry at 300 atm. or the hot material at 50 atm. A mixture of raw and highly calcined zirconia should be used (as it shrinks less than the raw zirconia, which polymerises at 1600°—1700° C.), and as soon as the articles are dry they may be burned in an electric furnace at 2000°—2300° C., only about 1 hour being required for crucibles 2 in. high and $1\frac{1}{2}$ in. diam. The addition of a small percentage of alumina or clay is advantageous, but magnesia and silica make the ware too porous. The importance of grading the zirconia into particles of suitable sizes appears to have been overlooked. Articles made of zirconia may be cast in plaster moulds, using a slip composed of graded zirconia and colloidal zirconia sol, the latter being prepared by repeatedly evaporating zirconium nitrate with 20 times its weight of water. The speed of translation of the particles of colloidal zirconia sol in an electric field was measured by the author; with a potential difference of 110 volts it averaged 2.2×10^{-5} cm. per second, for 1 volt with electrodes 1 cm. apart. The speed is seriously affected by electrolytes in the zirconia, and material to be used for casting should be washed free from negative electrolytes. According to Podszus (Eng. Pat. 11,771 of 1912; this J., 1913, 792) the particles of colloidal zirconia must not exceed 0.005 mm. diameter, and some particles not exceeding 0.1 μ to 1 μ should be present. The plasticity of zirconia slip and the ease with which it leaves the mould are related to its electrical properties. The proportion of water in the slip must be regulated according to the rate at which it is to be absorbed by the mould. Thus, for articles of complex shape a "thin" slip is preferable, as it is absorbed more slowly and there is less risk of the article splitting. Non-porous moulds may be used if they have a low coefficient of expansion and are lined with wax or other readily fusible or soluble material which may be removed before the article. For complex shapes a nickel mould coated internally with paraffin wax is suggested; to release the article from the mould the wax is melted and poured out. Ware with walls only a fraction of a mm. thick may be cast in this manner. Zirconia ware should be supported

on discs of carbon or zirconia and burned in an electric resistance furnace at 2000° C.; if burned at a higher temperature, its porosity is increased by the volatilisation of a further part of the impurities. Ware burned at 2000° C. is bluish-grey, at 2200° C. reddish-brown, and at 2400° C. bluish-black owing to absorption of carbon and the formation of carbide. The blue colour appears to be due to titanium oxide, the reddish colour to zirconium nitrocarbide. Pieces of zirconia ware which have been burned under slight reducing conditions have a handsome purple brown colour, and, when polished, resemble black marble. They are very strong, and may be dropped on a hard floor with impunity. If reheated at 1000° C. in a muffle, the colour changes to a yellowish-white, and the expansion due to reoxidation makes the ware porous and liable to spall. Vessels of clay or other refractory materials may be lined or coated externally with zirconia, but such a method of protection has only a limited applicability. Zirconia ware has not hitherto been glazed satisfactorily; a glaze composed of felspar 22.4, alumina 40.8, zirconia 147.6, magnesite 50.4, and quartz 69.6 parts burned on the ware at 1900°—2000° C., is fairly satisfactory and does not craze, but is rather matt and liable to blister. There is a strong tendency for the zirconia to combine with glazes melting at a lower temperature, though when the product is sufficiently refractory they may be used.—A. B. S.

PATENTS.

Plate glass; Pot for the manufacture of — and method of making the same. C. H. Kerr, Tarentum, Pa., Assignor to Pittsburgh Plate Glass Co. U.S. Pat. 1,278,164, 10.9.18. Appl., 18.12.16.

PLASTIC refractory clay is thoroughly mixed with from 15% to 50% of silica, which is so finely divided that the major portion of it consists of grains less than 0.005 in., preferably less than 0.0025 in. diameter.—B. V. S.

Kiln for ceramic ware. O. von Horstig, Saarbrücken. Ger. Pat. 306,726, 3.7.14.

In a zig-zag ceramic kiln the end chambers are connected by a canal, which passes over or under the other chambers, and is provided with firing doors and adapted to receive articles to be baked.
—J. H. L.

Porcelain and other clay wares; Half-gas firing for smokeless burning of —. J. Pepp, Bunzlau. Ger. Pat. 307,902, 29.9.16.

The ware is burned in an oven fitted with deep vertical fire-boxes with sloping, water-cooled grates which project beyond the fire-boxes. The grates are covered by narrow slides which are moved reciprocally by mechanical means. By this means the production of smoke and clinker is avoided even when low-grade fuel is used. The absence of irregular stoking, heavy poking, and soot results in a considerable saving in fuel and labour.—A. B. S.

IX.—BUILDING MATERIALS.

Calcium aluminium sulphate as a concrete destructor. Nitzsche. Z. angew. Chem., 1918, 31, 195—196.

A DISCUSSION of the formation of the double sulphate of calcium and aluminium in cement and its deleterious action. The compound is always formed when a solution of a sulphate is brought into contact with lime water and precipitated alumina, but it is

only stable in presence of free lime. Most natural waters contain sulphate and consequently attack cement, but sea water appears not to lead to the formation of the double calcium aluminium sulphate. The preventive measures recommended are the coating of the cement with bituminous material, or the modification of the constitution of the cement in such a manner as to prevent the formation of the double sulphate.—E. H. R.

PATENTS.

Cement shaft-kilns; Apparatus for loading — and pre-drying the material. Lothringer Portland Cement Werke, Strassburg, Alsace. Ger. Pat. 306,514, 23.1.17.

INSIDE the superstructure of the kiln, and exposed to the hot gases from the latter, is a hopper situated centrally above the kiln shaft. The material delivered by this hopper falls against the sloping sides of a hollow cone, also situated centrally, base downwards, at a somewhat lower level. The lower portion of the sides of this cone is formed of grids which allow the smaller particles to pass through, so that they fall in the central part of the shaft, whilst the larger pieces are deflected by the cone towards the kiln walls. This prevents caking of the finer material on the walls.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Slag control in the iron blast furnace by means of slag viscosity tables. A. L. Feild. Chem. and Met. Eng., 1918, 19, 294—300.

THE diminution of slag viscosity with increase of temperature is shown in the form of a curve, and

by means of this it may be demonstrated that a minor change in percentage of one of the principal constituents—lime, alumina, and silica—may cause a great change in the temperature-viscosity relations. A gradual increase in the amount of lime, instead of producing a gradual change in viscosity, produces maxima and minima. Changes in percentages of minor constituents of a slag, such as oxides of magnesium, manganese, iron, etc., do not appreciably affect temperature-viscosity relations if the percentage of magnesia, the most important minor constituent, does not exceed 8%. The temperature relations of the slag are said to be most suitable with a viscosity ranging from 10 in the furnace to a viscosity of 4 where the slag leaves the furnace. In controlling the slag between these limits, it is shown that all calculations of slag analyses must be made on a basis of 100% of lime, alumina, and silica; lime must be accurately determined by analysis and not by difference, as slag properties are particularly susceptible to slight differences in the lime content. With a given supply of raw materials—ore, coke, and limestone—the economy in coke consumption for a specified grade of iron is chiefly dependent on the maintenance of a proper slag composition. Examples are given of the necessary calculations, with ores of known percentage composition, showing how the amount of limestone per pound of pig iron of a definite composition may be calculated so as to arrive at a slag of the proper viscosity by making use of the slag-viscosity tables. (See also this J., 1918, 61 A, 246 A, 518 A.)—B. N.

Cast iron; Wearing and antifrictional qualities of —. J. E. Hurst. Iron and Steel Inst., Carnegie Scholarship Memoirs, 1918, 9, 59—76.

WEAR in commercial grey cast iron appears to be brought about by a process of surface disintegration, individual grains of hard eutectic being detached bodily. This debris may be largely instrumental in bringing about "seizing" in moving parts. Subsequently to this stage the plastic constituents flow into the cavities formed, and yield a well-glazed surface of excellent antifrictional qualities, with harder particles standing up in slight relief. The iron should not be too "open" in texture. There does not appear to be any relationship between wearing properties in cast iron and its Brinell hardness. The casting temperature of the iron is said to affect the antifrictional qualities, but in what way is not stated. Two machines designed to afford laboratory tests on the wearing properties of samples of cast iron are described.

—F. C. Th.

Steel manufacture; Balanced reactions in —. A. McCance. Faraday Soc., Nov. 12, 1918. [Advance proof.] 11 pages.

DURING the melting process in the open-hearth furnace, as the temperature becomes lower there is greater oxidation of the scrap and more FeO in the slag, as following analyses show:—

	FeO	SiO ₂
" Cold heat "	36.3	36.4
" Hot heat "	20.8	45.0

It is suggested that this oxidation is largely due to steam in the burnt producer gases: $3\text{Fe} + 4\text{H}_2\text{O} = \text{Fe}_3\text{O}_4 + 4\text{H}_2$. Thus to minimise loss due to scaling it is necessary to melt down quickly and at a high temperature and to have a low steam content in the burnt gases. So long as the bath of steel lies under a covering of slag containing ferrous oxide, this will be present in solution in both steel and slag, the ratio of the two concentrations being always constant. The ferrous oxide in solution in the steel reacts with the carbon also present forming

carbon monoxide, which, when the metal has become supersaturated, is evolved. So long as no new ore additions are made to the bath a straight line is obtained when the logarithm of the carbon in the bath is plotted against the time. The volume of gas present in deoxidised steel is greater than that in steel not so treated, and further the CO_2 :CO ratio is much greater in the deoxidised material.—F. C. Th.

Steel; Gases occluded in ——. T. Baker. Faraday Soc., Nov. 12, 1918. [Advance proof.] 4 pages.

The gases evolved when samples of steel were heated *in vacuo* to about 1000°C . were collected, measured, and analysed, the results being summarised in the following table:

Description	Vol. of gas in c.c. per grm. of steel	Composition				
		CO_2	H_2	CO	CH_4	N_2
Sound steel, 0.9% C ...	1.32	1.68	52.00	45.53	0.72	0.07
Do. reheated ...	1.40	1.16	49.55	45.99	2.71	0.59
Steel with blow-holes ...	0.66	0.88	54.56	42.36	1.73	0.47
Soft ingot ...	1.03	1.18	52.12	45.64	0.73	0.33
Bar from soft ingot ...	0.53	0.91	49.08	48.12	0.11	1.77

The steel with blow-holes contains less gas than does the sound steel. Reheating to 1200°C . does not appreciably alter either the volume or the composition of the gases. Forging reduces the volume of occluded gas considerably, but does not result in any marked alteration in the composition. With hard steels hydrogen reaches a maximum rate of evolution at 600°C ., and below this temperature constitutes the greater part of the gas given off. Carbon monoxide is slowly evolved from the start, and reaches its maximum rate of evolution at 688°C .. With soft steels hydrogen again forms the greater part of the gas collected up to 660°C ., and presents a maximum at 609°C .. The carbon monoxide is evolved most quickly at 786°C ., at which temperature a second maximum in the rate of evolution of the hydrogen occurs.—F. C. Th.

Strain in iron and steel; Chemical detection of — by their reaction with nitric acid. J. H. Whiteley and A. F. Hatfield. Iron and Steel Inst., Carnegie Scholarship Memoirs, 1918, 9, 1—56.

The final reduction products obtained when iron is dissolved in dilute nitric acid are chiefly nitrogen peroxide, nitric oxide, nitrogen, and ammonia, depending on the acid-strength and the degree of cold work put upon the iron. At an acid-strength of 24 grms. per 100 c.c. the reaction undergoes a marked change, much of the nitrogen and ammonia being replaced by oxides of nitrogen. By plotting as ordinate the weight of iron consumed in forming nitrogen and ammonia and as abscissa the acid-strength, a characteristic "reaction curve" is obtained. Progressively increasing strain in the sample results in a progressive shifting to the right of the "reaction curve." Strained iron subsequently annealed at 520°C . becomes from this point of view unstrained. Differences in grain size in annealed pure iron do not produce perceptible differences in the reaction curves.—F. C. Th.

Iron; Protection of — with paint against atmospheric corrosion. J. N. Friend. Iron and Steel Inst., Carnegie Scholarship Memoirs, 1918, 9, 77—123.

ACCELERATION tests are of little value. Reliable results can only be obtained from tests carried out under practical conditions. Addition of pigment to

oil increases the efficiency of the latter as a protective agent up to a maximum, after which further addition of pigment causes deterioration. The best results are obtained from paints possessing as high a percentage of good oil as is compatible with a good body. Linseed oil expands on setting, which results in crinkling and cracking. Linoxyn is permeable to moisture, the permeability being reduced by heating in absence of air. Polymerised linseed oil affords better protection than raw oil. A thick coat of paint, so long as it is not so thick that crinkling occurs, protects the metal better than a thin one. The best results are obtained by multiple coats, two thin ones being better than one thick one. Turpentine has little effect on the efficiency of a paint. The most permanent paints are those containing black and red pigments. Fine pigments afford more efficient protection than coarse pigments. Iron should be painted while the scale is still on, with loosely adherent flakes scraped off. The paint will then last longer than if applied to the pickled or sand-blasted surface. Experiments with rusty plates, though not conclusive, suggest that rust need not be so completely removed prior to the painting as is usually thought to be necessary.—F. C. Th.

Tinplate; Metallographic examination of —. L. Mayer. Stahl u. Eisen, 1918, 38, 960—962.

The softness of metallic tin made it necessary repeatedly to etch and polish the surface to be examined before a satisfactory specimen could be obtained. Very dilute (2%) nitric acid is the best etching medium; picric acid does not attack tin, but may be used on the tin-free iron surface. The surface of the specimen was first electroplated with copper; a portion of the surface was then polished, etched with the dilute nitric acid to display the tin crystals, and finally with an alcoholic solution of picric acid to display the ferrite and pearlite in the iron. The tin crystals were small and elongated; no indication of any compound of tin and iron was found, though the thickness of the tin coating varied from 0.002 to 0.01 mm. Small iron cubes measuring $10 \times 15 \times 20$ mm. were polished, pickled in dilute hydrochloric acid, washed with distilled water, dried in a bath of zinc chloride, and then tinned by immersion for half an hour at 300° , 500° , 750° , and 950°C . respectively. On examining the specimens under the microscope, there appeared to be a layer of intermediate crystals which increased in thickness as the temperature of the bath increased. At 750°C ., with low-carbon iron and at 500°C . with high-carbon iron, a reduction in the amount of pearlite occurred in the layer adjacent to the tin coating. At 950°C ., pearlite again appeared at the edges of the tin coating; with the purest iron, the formation of small crystals within the larger ferrite crystals was observed in the neighbourhood of the tin coating. The diffusion of tin into iron may be shown indirectly by the behaviour of pearlite and ferrite at high temperatures. (See also J. Chem. Soc., Dec., 1918.)

—A. B. S.

Lead in tin-plate; Volumetric determination of —. J. Deininger. Z. Unters. Nahr. Genussm., 1918, 36, 66—67.

ABOUT 0.5 gm. of the metal is heated with 10 c.c. of concentrated sulphuric acid until metallic particles are no longer visible; after cooling, 20 c.c. of 5% ammonium oxalate is added and the mixture again heated in order to dissolve remaining traces of iron. Alcohol is then added, the lead sulphate collected, washed with dilute alcohol, then dissolved in 15 c.c. of hot 50% sodium acetate solution, and bromine water added, drop by drop, to the warm

solution until a slight excess is present. After 5 mins., the precipitated lead peroxide is collected, washed with hot water, rinsed into a beaker with cold saturated sodium acetate solution, and treated with 20 c.c. of 5% potassium iodide solution and 10 drops of acetic acid; the lead peroxide decomposes rapidly, and the liberated iodine is titrated with thiosulphate solution. Each c.c. of N/10 thiosulphate solution is equivalent to 0.01036 gm. Pb. The lead sulphate obtained by the treatment with sulphuric acid contains tin, and if weighed directly the results obtained are much too high.

—W. P. S.

Soft iron and copper; Hardness of — compared.
F. C. Kelley. Amer. Electrochem. Soc., Sep.-Oct., 1918. [Advance copy.] 4 pages.

By annealing samples of American "ingot iron" and ordinary commercial cold-rolled copper similarly, in hydrogen and in a vacuum, at temperatures between 770° and 950° C., the Brinell hardnesses of the metals as received were reduced from 95 and 80 to 60 and 40, respectively. It is suggested that such dead soft iron—which, in the present case, could be whittled with a knife—might find uses in place of pure soft copper.

—W. E. F. P.

Brass melting; Present status of electric —.
H. M. St. John. Chem. and Met. Eng., 1918, 19, 321—328.

It was estimated by Gillett, in 1911, that the value of the metal employed in brass and bronze melting in the United States was \$120,000,000 per annum, whilst the value of the metal lost during the melting operation was \$3,000,000. Most of the developments in electric furnace melting have been designed to eliminate much of this loss. The advantages which may be expected to accrue from electric melting are metal saving, improved quality, exact temperature control, increased production, elimination of crucible cost, other incidental savings, and better working conditions. The principal requirements in electric melting are uniform heating of the metal, uniformity in composition on pouring, and a high thermal efficiency consistent with good metallurgical results; and the electrical characteristics of the furnace must be such as to make it a desirable load for the central station company or the factory power plant. Of the four types of electric furnace available, the vertical ring induction furnace is of high efficiency, limited in its application, but within its limited range gives satisfactory results. The indirect-resistance, indirect-radiation furnace is less efficient, has a lower rate of production in proportion to its holding capacity, but is more flexible and better suited to general foundry use, though neither form is entirely satisfactory. The indirect-arc is more efficient than the indirect-resistance, and more flexible within its own field; it may be advantageously used for alloys with no zinc, or with only a small percentage. The most promising possibilities are stated to be in an induction furnace not only efficient but flexible and of wide-spread application, or in a form of arc furnace which will be applicable to yellow brass and other high-zinc alloys, as well as to the less sensitive alloys. Electric crucible furnaces, though reliable and effective, are hardly likely to be profitable. The application of electricity to brass-melting, from the central station viewpoint, is discussed, and it is stated that the power company should be familiar with the electrical and operating characteristics of the different furnaces in use, so as to prevent mis-applications, whilst pointing the way to correct use and ensuring profitable development.—B. N.

Antimony; Electrolytic refining of —. [Extraction from low-grade ores.] Y. C. Wong. Chem. and Met. Eng., 1918, 19, 509.

LOW-GRADE ores are not a commercial source of antimony at the present time; but during the last 30 years processes depending on the treatment of such (sulphide) ores with a solvent (sodium sulphide, etc.), and the recovery of metallic antimony from the solution by electrolysis, have been used more or less successfully. Siemens and Halske (Eng. Pat. 18,966 of 1892; this J., 1893, 847) in 1892, and von Engelhardt and Nettel in 1896, employed as solvents solutions of alkaline-earth sulphides which were subsequently regenerated with only small losses; and from these solutions 0.621 kilo. of antimony per kilowatt-hour (representing an efficiency of 76%) was deposited with a current density of 0.8 amp. per sq. cm. at 0.8 volt. In laboratory tests made by the author on the electrolysis of calcium thioantimony salts in aqueous solutions, an anode of platinum wire in the form of a helix was surrounded by a cylindrical cathode of platinum foil having an exposed surface of 39.3 sq. cm. With a current of 0.4 amp. at 1–1.2 volts, 90% of the antimony was deposited in one hour from about 450 c.c. of hot solution containing 0.962 gm. of the metal. The cost of extraction by this process is estimated at 5c. (2½d.) per lb. of metal recovered.—W. E. F. P.

Pyrophoric alloy industry; The American —. A. Hirsch. Chem. and Met. Eng., 1918, 19, 510—512.

The history of the industry is briefly outlined, with special reference to the production of metallic cerium and pyrophoric alloys in the U.S.A. by the New Process Metals Co., operating under U.S. Pat. 1,273,223 (see this J., 1918, 591 A). According to this process, so-called metallic cerium ("Mischmetall") is prepared from the mixed rare-earth metal oxides obtained as a by-product in the extraction of thorium from monazite. The mixed oxides (mainly cerium oxide) are dissolved in hydrochloric acid and the solution after purification is evaporated to dryness; the residue is fused and electrolysed in cast iron pots which are heated when necessary during the operation. The pot constitutes the cathode of the cell, the anode being a rod of carbon or graphite; each of the latter materials has a critical current density (5½ and 6–7 amp. per sq. in. of surface, respectively) above which current may pass without deposition of metal. To secure a desirable electrical heating effect, the current density maintained at the anode is from 3 to 4 times that at the cathode. At the conclusion of the electrolysis, the charge is allowed to cool in the pot, and the latter is broken to remove the button of "Mischmetall," which is then alloyed with about 30% of other metals (chiefly iron) to produce the commercial sparking metal or pyrophoric alloy.—W. E. F. P.

"Uico" hard metal [lead alloy]. F. C. Frary and S. N. Temple. Chem. and Met. Eng., 1918, 19, 523—524.

"Uico" hard metal, originally designed as a substitute for antimonial lead, is an alloy of lead with considerably less than 1% of calcium or/and other alkaline-earth metals. It is much harder than other commercial lead alloys, and expands on solidification, forming castings free from blow-holes. The Brinell hardness of antimonial lead is about 17; that of chilled castings of Uico metal varies from about 22 to 26, according to the temperature of pouring, and the alloy can be remelted several times without appreciable loss of hardness. Uico metal has the general appearance and mechanical properties of ordinary lead, and may

be diluted with the latter, or with tin or bismuth, to produce softer alloys the hardness of which increases on "ageing" for a few days; but the addition of antimony causes separation of the alkaline-earth metal. In comparative tests made by the U.S. Bureau of Standards on machinery bearings of genuine Babbitt metal and Ulco hard metal, the latter gave highly satisfactory results. The Babbitt metal had a tensile strength of 10,000 lb. per sq. in. and, on 1 inch, gave an elongation of 15% and a reduction of area of 8%. The corresponding figures for the lead alloy were 13,000 lb., 5%, and 1%, respectively, the average elastic limit in compression being 11,525 lb. per sq. in. The alloy is also recommended for use in the production of small castings at present made from brass.—W. E. F. P.

Alloys; Determination of the composition of binary — by specific gravity determination. M. von Schwarzh. Bayr. Ind. u. Gewerbebl., 1918, 104, 61–63. Z. angew. Chem., 1918, 31, Ref., 310.

In determining the specific gravity of alloys by Matthiessen's formula, $d = 100 / \left(\frac{A}{a} + \frac{B}{b} \right)$, where A

and B are the percentages of the two metals in the alloy and a and b their specific gravities, an allowance must be made for the alteration in density due to contraction and in a few cases for that due to expansion. The method of using the sp. gr. as a means of determining the composition finds practical application principally for tin-lead and antimony-lead alloys, of which samples of definite volume can be cast and their weight compared with those of similar substances of known composition on the so-called tin assay balance. Instead of the usual disc or conical samples, balls are now used which can be obtained uniform and of an exact volume. Using balls of a volume of 1.62 c.c. and weighing to 0.01 grm., the composition of tin-lead or antimony-lead alloys can be obtained from the sp. gr. curves with an accuracy within the limits of 0.5–1.0%.—W. G.

Gallium. L. M. Dennis and J. A. Bridgman. J. Amer. Chem. Soc., 1918, 40, 1531–1561.

SPARK spectra are suitable for detecting amounts of gallium above 0.0046 mgrm. and amounts of indium above 0.0013 mgrm. In the presence of gallium, 0.06% of its weight of indium can be detected by means of the spark spectrum and 0.18% of gallium can be detected in the presence of indium. Fractional electrolysis, after 14 operations, yields pure gallium from a mixture of gallium and indium, whilst fractional distillation of a mixture of the chlorides of gallium, indium, and zinc yields pure gallium chloride. Gallium is best estimated by precipitation from slightly acid solutions as hydroxide by means of sodium sulphite. Mixtures of gallium and zinc are separated and estimated by adding an excess of potassium mercuric thiocyanate to a slightly acid (H_2SO_4) solution of the sulphates. After keeping for several hours the precipitate of zinc mercuric thiocyanate is collected in a Gooch crucible, dried at 105°–110° C., and weighed. The filtrate is acidified with hydrochloric acid and the mercury removed by hydrogen sulphide; after boiling, the gallium is precipitated as hydroxide by means of sodium sulphite. Mixtures of gallium and indium are separated and estimated as follows: Solutions containing small amounts of both elements are largely diluted and treated with a small amount of hydrochloric acid and exactly neutralised with sodium hydroxide, an excess of 1.5 grms. of sodium hydroxide is added, and the solution boiled for

several minutes. The precipitated indium hydroxide is well washed, dissolved in hydrochloric acid, and the process repeated. Finally it is dissolved in hydrochloric acid, precipitated by ammonia, washed, dried, ignited, and weighed as oxide. The filtrate and washings from each precipitation are combined and the gallium precipitated as before. The separation of gallium and aluminium is effected in the following way: The aluminium is precipitated as hydrated chloride by adding 60 c.c. of hydrochloric acid to the solution and then 60 c.c. of ether. The flask is immersed in cold water and the solution saturated with hydrogen chloride, when hydrated aluminium chloride is precipitated. This is collected in a Gooch crucible, washed with a mixture of 30 c.c. of hydrochloric acid and 30 c.c. of ether and then dissolved in water and the aluminium estimated in the usual way. The combined filtrates and washings are treated with a small amount of sulphuric acid and boiled to expel ether and most of the hydrochloric acid, and the gallium estimated as before. Methods are given for the estimation of mixtures of gallium, indium, and zinc, and gallium, indium, zinc, and aluminium. (See also J. Chem. Soc., Dec., 1918.)—J. F. S.

Electric welds. E. E. Thum. Chem. and Met. Eng., 1918, 19, 301–308.

MACHINES are described for use in butt and spot welding, in which increased speed is obtained in the operation, and the formation of undesirable oxides is avoided. Considerable trouble was at first experienced in spot welding a small inset of high-speed steel into a carbon-steel tool, through the breaking away of the tool steel, but this was afterwards prevented by slowly annealing the material in lime in a hot oven and later hardening. To study the chemical and physical changes induced by the welding process, pieces of drill steel, 0.97% carbon, were butt welded and afterwards turned, tested for ultimate strength, and examined metallographically. The unannealed welded bars were found to have a higher ultimate strength than the original bar, and in the annealed bars the marked increase in ductility near to the weld suggested a change in the carbon content; metallographic examination showed a decarburised zone, and this was confirmed by analysis. A welded bar, not heat treated, will break at some distance from the joint under static load, but at the weld if tested under sharp, eccentric impact. After heat treatment, exactly the opposite will occur, as the joint will then be the weakest and most ductile part of the bar due to local decarburisation. Photomicrographs are shown illustrating the changes that take place in various types of steel in spot and butt welding, and showing the development of a eutectiform structure in spot welds. The eutectiform appearance has been shown to be identical in nature with the Widmanstätten bands, consisting of a concentration of excess ferrite along the octahedral cleavages of austenite.—B. N.

PATENTS.

Manganese steel; Producing wrought shapes of — W. S. Potter, Pittsburgh, Pa. U.S. Pat. 1,278,207, 10.9.18. Appl., 11.5.14. Renewed 1.6.18.

The steel ingot is heated to a temperature within the range of 200° C. above the critical temperature (about 825° C.), for a sufficiently long time to allow of re-absorption by the mix crystals (solid solution) of the metal of the excess carbides of the eutectic and any carbides which may have separated; the metal is subsequently heated to a temperature suitable for the ductility required, and then subjected to reduction.—T. H. B.

Ferro-molybdenum; Process of making — E. H. Westling (Assignor to N. W. Stern) and C. Andersen, San Francisco, Cal. U.S. Pat. 1,278,408, 10.9.18. Appl., 18.11.16.

An acid solution of molybdic acid, containing a ferrie salt, is neutralised with an alkaline basic compound, the precipitated ferrie molybdate separated, and heated in presence of a reducing agent.—T. H. B.

Iron and steel scrap; Utilisation of — Preparation of briquettes of iron and steel scrap in admixture with carbon. Deutsch-Luxemburgische Bergwerks- u. Hütten-A.-G., Bochum. Ger. Pats. (a) 304,872, 24.2.16, and (a) 307,834, 2.6.17.

(A) TURNINGS and planings of iron and steel are heated to incandescence and then made into briquettes, which are subsequently smelted. Scrap from special steels can be worked up in this way and then charged direct into an open-hearth furnace. (B) A mixture of scrap iron or steel and carbon is briquetted as described under (A) or is charged into a rotary kiln wherein it is heated by a reducing flame.

Tin and wolfram ores; Concentration of — W. W. Webster, E. Edser, and L. A. Wood, London. Eng. Pat. 119,050, 14.6.17. (Appl. 8563/17.)

BEFORE concentration by means of tables, vanners, etc., the ore is subjected to the action of sodium or potassium hydroxide, silicate, carbonate, or phosphate, ammonia, borax, or silicic acid sol. The process is more particularly applicable to the treatment of slimes.—W. E. F. P.

Smelting and refining metallic swarf and the like; Furnaces for — J. Tylor and Sons, Ltd., H. T. White, J. Gaunt, and D. Brookfield, London. Eng. Pat. 119,779, 14.1.18. (Appl. 802/18.)

In a furnace of the type having a metal preheater (see Eng. Pat. 118,750; this J., 1918, 659 A), the preheater communicates with an inclined tubular extension, which contains a trough of semi-circular cross-section so arranged that the flue-gases rising from the furnace through the tubular extension have free access to all sides of the trough. Swarf is charged into the trough through suitable openings in the tubular flue and is melted down, and discharged into the crucible from the lower end of the trough.—C. A. K.

Furnaces for heating metal articles and the like. W. H. Southorne, North Shields. Eng. Pat. 119,787, 22.1.18. (Appl. 1230/18.)

The furnace, which is specially applicable to the hardening or annealing of steel tools, gauges, and

the like, has a removable, revolving bottom, the upper surface of which is corrugated or roughened to permit free access of air or gases to the articles resting thereon. The furnace is heated by burners so arranged that the flames do not impinge directly upon the articles.

Furnaces for heating tools and other articles; Gas-fired — H. J. Yates, Birmingham, and S. N. and E. R. Grayshaw, Manchester. Eng. Pat. 119,817, 19.3.18. (Appl. 4797/18.)

The improvements described in Eng. Pats. 22,522 of 1907 and 23,066 of 1911 in relation to methods of operating the doors of furnaces, and in Eng. Pat. 110,960 (this J., 1917, 1266) in relation to burners, are combined in a single furnace.

Hot-blast stove; Four-pass — J. I. Larimer, Joliet, Ill. U.S. Pat. 1,278,173, 10.9.18. Appl., 7.11.16.

The first and fourth passes are symmetrically disposed on opposite sides of the stove; the intervening space is bisected by a wall to form the second and third passes. Metal checker-work is used near the end of the last pass and is composed of a number of units, each consisting of spaced webs providing narrow vertical passages, "vertically adjacent units being relatively angularly disposed." (See also U.S. Pat. 1,265,923; this J., 1918, 473 A.) —C. A. K.

Aluminium or its alloys; Autogenous welding of — A. Carpmuel, London. From A.-G. für Autogene Aluminium Schweissung, Zürich. Eng. Pat. 120,005, 29.5.18. (Appl. 8874/18.)

A FLUX for use in the autogenous welding of aluminium or aluminium alloys consists of a mixture of alkali halides, having the required fusibility, and comprising at least three different members of the halogen group, of which fluorine must be one. A suitable mixture contains: KCl 40%; NaCl 30%; LiCl 10%; KBr 10%; NaF 10%. The melting point of this mixture is about 600° C.; for use in the welding of alloys, the melting point of the flux may be reduced by an alteration in the proportions of the mixture, or by the addition of an alkali iodide.—C. A. K.

Ore concentration. F. Gooch, Cobalt, Ont., Canada. U.S. Pat. 1,276,753, 27.8.18. Appl., 25.5.16.

In an apparatus for concentrating ores by the agitation-froth process, a centrifugal agitator and distributor, comprising radial impeller blades enclosed by upper and lower plates, is provided in the agitation and froth-decantation chamber. The agitator is mounted upon a hollow shaft through which the apparatus is charged with ore pulp and air.—W. E. F. P.

Subliming and sintering ores; Method and apparatus for — W. H. Kilbourn, Pueblo, Colo., Assignor to United States Smelting, Refining, and Mining Co. U.S. Pat. 1,278,166, 10.9.18. Appl., 7.11.17.

The ore or similar material containing volatile metals is mixed with a large proportion of carbon and fed on to a horizontal travelling grate passing under an ignition arch in a combustion chamber. A series of depressions is formed in the upper surface of the bed of ore, and a blast of air is passed through the grate under the ignition arch.

—B. V. S.

Nickel-matte or nickel-copper matte: Method of treating —. O. Lellep, New York. U.S. Pat. 1,278,176, 10.9.18. Appl., 11.10.17.

NICKEL-CONTAINING matte is subjected to the action of an oxidising agent at a temperature between the melting points of the matte and of nickel oxide. The furnace conditions should be non-reacting (non-acidic).—C. A. K.

Electric welding; Process of —. J. B. Murray, Brooklyn, N.Y. U.S. Pat. 1,278,193, 10.9.18. Appl., 22.3.18.

THE parts to be welded are electrically heated to a welding temperature, and at the same time subjected to pressure. The heating is then stopped, but the pressure is maintained until the critical cooling range has been passed.—C. A. K.

Alloy. H. S. Cooper, Assignor to The General Alloys Co., Cleveland, Ohio. U.S. Pat. 1,278,304, 10.9.18. Appl., 23.2.18.

AN alloy containing a preponderating amount of nickel, and 0.5–15 or 0.5–20% of zirconium, with relatively small amounts (1–20% in all) of aluminium and silicon.—T. H. B.

Alloy, and method of purifying same. P. Poetschke, Assignor to L. D. Caulk Co., Milford, Del. U.S. Pat. 1,278,744, 10.9.18. Appl., 7.2.18.

COMMUNUTED alloys are placed in trays having permeable bottoms, and are purified by treatment with acidified alcohol, then washed in water, dehydrated with alcohol, and dried in a current of air.—T. H. B.

Electric [metallurgical] furnace and method of supplying current thereto. J. H. Gray, New York. U.S. Pat. 1,278,635, 10.9.18. Appl., 20.7.18.

A CURRENT of comparatively high E.M.F. is supplied to the electrodes of an electric furnace during the melting down period, to produce a long arc, and during the refining period a current of lower E.M.F. is substituted to avoid surges on the power line. A reactance coil is fitted in circuit with the primary windings of the transformer to effect a higher E.M.F. on the secondary winding, and after melting the metal down this reactance coil is cut out of circuit so as to reduce the E.M.F. in the secondary coils of the transformer.—C. A. K.

Reduction of metallic oxides, especially iron oxides; Process for the —. G. Gröndal, Djursholm, Sweden. Ger. Pat. 306,261, 25.11.15.

A LAYER of the finely divided metallic oxide, covered with a charge of finely divided coal or other fuel, is first heated by combustion of the latter in a current of air drawn or forced downwards through the charge; when the desired temperature has been attained the air current is so diminished as to produce carbon monoxide, by which the metallic oxide layer is reduced. At 700° C. the reduction of iron oxide by carbon monoxide takes place with practically no absorption of heat. If necessary a layer of lime may be interposed between the fuel and the metallic oxide, to desulphurise the gases before they reach the latter. The process may be carried out in a suitably lined cast-iron holder, open at the top, provided with a suction pipe for the gases at the bottom, fitted inside with a grate near the bottom to support the charge, and mounted on trunnions to enable it to be inverted.—J. H. L.

Zinc: Production of — of high purity from impure metal and alloys in vacuo. E. Herter, Berlin. Ger. Pat. 306,725, 6.6.15.

IN the vacuum distillation of zinc the condensed liquid metal is continuously drawn off, without impairing the vacuum, by maintaining a column of the liquid metal of sufficient height to balance the atmospheric pressure.—J. H. L.

Blast-furnace gas; Apparatus for purifying —. A. M. Fasel, Mülhofen. Ger. Pat. 306,853, 11.3.16.

FOR the removal of dust the gases are conducted, through inclined ducts, across the open tops of vertical chambers or fall-pipes from the lower ends of which the deposited matters can be discharged at intervals. The ducts are connected by inclined curved end-tubes from which fall-pipes extend downwards. At suitable points the passage of the gases may be obstructed by dampers extending across the lower half of the cross-section of the ducts or end-tubes.—J. H. L.

Lead-tin alloys. W. Stockmeyer, Minden, and H. Hanemann, Charlottenburg. Ger. Pat. 306,892, 14.9.15.

CLAIM is made to alloys of lead and tin containing sodium or magnesium or both and if desirable some copper. Small quantities of sodium or magnesium appreciably increase the hardness of lead, and the addition of tin to such alloys renders them less brittle and chemically more resistant; small quantities of copper further increase their hardness.—J. H. L.

Annealing furnaces [; Means for moving articles through—]. Greenwood and Batley, Ltd., and W. Clegg, Leeds. Eng. Pat. 119,841, 24.6.18. (Appl. 10.379/18.)

Tin-plates or sheets and other like metal coated plates or sheets; Appliances used in the manufacture of —. H. S. Thomas, Llandaff, and W. R. Davies, Whitechurch, Glamorgan. Eng. Pat. 119,969, 21.1.18. (Appl. 1140/18.)

Smelting furnace. E. K. H. Lundberg, Bruzaholm, Sweden. U.S. Pat. 1,278,696, 10.9.18. Appl., 14.7.16.

PATENTS.

Electro-osmosis; Apparatus for removal of water by means of —. Bergmann Elektrizitäts-Werke A.-G., Berlin. Ger. Pat. 307,242, 16.5.17.

The walls of the cells are constructed of insulating material, e.g., concrete, in which the electrodes can be mounted without special insulation. The cells may be cylindrical holes in a block of concrete.

—J. H. L.

Diaphragms for electrolytic purposes. Siemens u. Halske A.-G., Berlin. Ger. Pat. 307,471, 22.8.16.

DIAPHRAGMS particularly suitable for use in chlorine-alkali electrolytic cells with horizontal electrodes, are made from a mixture of powdered cement and cellulose or material containing cellulose, mixed to a pulpy mass with water. The diaphragms so obtained are strong and somewhat pliable and possess excellent porosity. The porosity can be varied by varying the proportion of cellulose employed. They possess the advantage of cheapness over the Billiter asbestos diaphragms, and are fairly stable. They are more simply prepared than asbestos-cement diaphragms or diaphragms containing cow-hair or wool.

—J. S. G. T.

Diaphragms used in electrolysis; Supports for —. Farb. vorm. Meister, Lucius, u. Brünning. Ger. Pat. 307,521, 18.12.17.

In electrolytic processes employing pulpy diaphragms, the diaphragms are usually supported on a grid of wire gauze. In the course of the electrolysis, owing to causes such as variations in the lengths of the individual wires of the grid, the grid buckles and the material of the diaphragm accumulates on the lower parts of the grid, with consequent unequal distribution of current in the electrolyte, and unequal destruction of the anode. According to the present patent a diaphragm support formed of rods is used, which, despite alterations of length, remains plane and in its original position: for example the rods may be left free at the ends to allow for expansion.—J. S. G. T.

Producing gas. Eng. Pat. 119,885. See IIa.

Electric furnace. U.S. Pat. 1,277,899. See VII.

Electric furnace. U.S. Pat. 1,278,635. See X.

XII.—FATS; OILS; WAXES.

"Sélé," "Cocorico," and *Ximonia americana*: African oil-yielding plants. J. Pierarts. Ann. Musée Colon. Marseille, 1916, 4, Pt. 2, 1—21. Bull. Agric. Intell., 1918, 9, 1060.

Sélé is the local name of an oil popular among the natives in certain parts of the Belgian Congo. A specimen of the oil prepared locally at Mombasa (Bengala district) consisted of the glycerides of oleic, "linoleic," stearic, palmitic, and lauric acids, in addition to a small quantity of an unidentified acid of higher molecular weight. Sélé oil may be classed as semi-drying, and is an excellent edible oil. It has good keeping qualities, is suitable for soap and glycerin manufacture, but unsuitable as a source of stearin owing to its low content of solid acids. Cocorico is a variety of *Citrullus vulgaris*. A specimen of the oil prepared locally at Yangambi

(Stanleyville district) had all the desirable qualities of sélé oil, but the low unit yield and the slow and difficult decortication of the seed render the latter useless for commercial purposes. *Ximonia americana* is a bush of the *Oleaceæ* family, abundant in Tropical America and the West Coast of Africa. The *Ximonia* is known by many local names peculiar to the different countries in which it is found, e.g. Jamalen, "mountain plum" or "sea plum"; Gabon, "elozy," "zégué," or "sea lemon"; South Africa, "zuur pruim" (acid plum). The "sea plum" is particularly valuable on account of its high oil content. The particular interest in the oil lies in its high content of linolenic acid and the special properties of its solid acids.—A. de W.

Elais poissonii, a new species of oil palm, in the Cameroons. Fauchère. Bull. l'Office Colon., 1918, 11, 80—83. Bull. Agric. Intell., 1918, 9, 1061.

The fruit of this oil palm is peculiar in that it is enclosed in a sort of fleshy sheath formed by the development of six staminodes contained in the female flower, which in the varieties of *Elais* hitherto described are always atrophied. The fruit weighs from 10 to 20 grms. The following table gives comparisons of the new species (of which two varieties are to be distinguished—var. *tenera* and var. *dura*) with the var. *Lisombe* of *Elais nigrescens* (the best form of oil palm known at present).

	<i>Tenera</i> %	<i>Dura</i> %	<i>Lisombe</i> %
Oil pulp	76	44	61.5
Nuts	24	56	38.5
Oil yield of the pulp... ..	70.25	58.6	63.15
Oil yield of the whole fruit	53.50	55.8	38.35

The following figures were obtained from an examination of ten fruits of each of the chief varieties of *Elais* in the Cameroons:—

	Fruit	Weight in grms.: Pulp Kernel	Oil
<i>Dibope</i>	123.0	51.5 23.0	27.0
<i>Lisombe</i>	121.5	76.5 20.5	47.0
<i>Dura</i>	171.0	74.2 18.1	44.0
<i>Tenera</i>	168.5	128.3 19.4	90.0

—A. de W.

Saponifiable fat and total fat. J. Prescher. Z. Unters. Nahr. Genussm., 1918, 36, 71—73.

The true fat content of a material (fatty acid plus neutral fat) is best ascertained from determinations of the free fatty acids, the total fatty acids, and the saponif. value.—W. P. S.

[*Lipolytic*] enzyme action; Influence of certain salts on —. I. S. Falk. J. Biol. Chem., 1918, 36, 229—247.

CALCIUM chloride inhibits the lipolysis of olive oil, and in its presence the point of equilibrium of the reaction mixture is reached much earlier than in its absence. The addition of sodium chloride tends to prevent the appearance of the calcium effect, although sodium chloride by itself exerts scarcely any action on the rate or equilibrium point of lipolysis.—H. W. B.

Drilling oils, etc. Marcusson. See IIa.

PATENTS.

Oil from vegetable fruits; Extraction of —. H. R. Greenhalgh, Rock Ferry, Chester, Assignee of N. A. Gayin, Kinshasha, Belgian Congo. Eng. Pat. 111,676, 28.11.17. (Appl. 17,577/17.) Int. Conv., 28.11.16.

In a process for extracting oil from the pericarp of fruits, such as palm-oil and similar nuts, the fruit

is subjected to a preliminary heat treatment in a jacketed kettle, and then transferred to a centrifugal extractor. If desired, the residual mat of combined fibre and nuts may be screened and the fibre pressed for the extraction of the remaining oil.—W. E. F. P.

Sulphur soap. T. Tanaka, Hongo-ku, Japan. U.S. Pat. 1,278,518, 10.9.18. Appl. 16.4.18.

See Eng. Pat. 117,060 of 1918; this J., 1918, 553 A.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Pigments for printing inks. T. M. Tyson. Oil and Colour Chem. Assoc., Nov., 1918, 1, No. 5.

PRINTING inks may be divided into two classes, viz., "litho" and "letterpress." The pigments used for the former class must be completely free from acidity, quite insoluble in water, possess good "solidity," moderate transparency, and not too high a specific gravity. Those for use in the manufacture of letterpress inks must be brilliant and opaque and when for use in process or three-colour work have low specific gravity. Printing ink pigments are preferably composed of dyes fixed on alumina, either alone or co-precipitated with *blanc fixe*, the lake and mineral pigments being simultaneously precipitated. Barytes or other abrasive material is quite useless as a base for either class of ink. The desiderata of a good printing ink pigment are principally brightness and strength, the latter property ensuring that sufficient printed impression will be obtained by the use of a very attenuated film, thus guarding against liability to "set-off" on the adjacent superposed sheet. Other properties of the pigment are required for special purposes, e.g., transparency and resistance to heat for tin-printing pigments, insolubility in alcohol for labels which are subsequently spirit varnished, resistance to alkali for use on soap wrappers. A classification into degrees of fastness to light and the adaptation to different purposes of pigments of varying stability to light, alkali, etc., is given, e.g., the special suitability of a fugitive, water- and spirit-soluble pigment, non-resistant to acid and alkali, for printing on cheques, etc.

—A. de W.

Protecting iron with paint. Friend. See X.

PATENTS.

Oil pastes from wet precipitated pigments; Manufacture of — and separation of free water therefrom. C. R. Rogers, Sydney, N.S.W. Eng. Pat. 118,289, 14.8.18. (Appl. 13,236/18.) Int. Conv., 24.7.17.

A small quantity of a soluble crystallisable salt having a slightly alkaline reaction, e.g., borax, is added during the milling of wet precipitated pigments with oil, in order to cause separation of water and facilitate incorporation of the paint stock with the oil.—A. de W.

White [antimony oxide] pigments; Manufacture of —. E. F. Morris, Roby, and T. N. C. Nevill, St. Helens, Lanes. Eng. Pats. (a) 119,711, (b) 119,712, and (c) 119,713, 17.10.17. (Appls. 15,022—4/17.)

(a) THE acidity of commercial antimony oxide due to contained sulphur compounds is neutralised by treating a mixture of antimony oxide in water with

acid-binding substances such as sodium carbonate, borax, or precipitated chalk or mixtures of these. *Example.* A thin mixture of antimony oxide and water is treated with about 0.5% (on the dry antimony oxide) of milk of lime, and boric acid, in proportions to leave the resulting solution faintly alkaline to litmus, and then drying the precipitate. (b) The contamination of antimony oxide with acid sulphur compounds, rendering it objectionable for use in paints, enamels, etc., is removed by treating the antimony oxide or oxide-containing pigment in a dry or comparatively dry state with an alkali or acid-binding substance, preferably whilst both are suspended in air. As examples, the oxide as made, before collection, is treated with gaseous ammonia, atomised alkaline substance (calcium borate), or an organic amine. The acid-binding substance may also be added to the oxide in powder form, preferably in the dampest state allowing fine grinding. (c) A pigment cheaper than antimony oxide but possessing some of its properties may be obtained by treating antimony sulphate with barium carbonate, so as to obtain a mixture of antimony oxide and barium sulphate. *Example.* 100 lb. of antimony oxide is treated with 112 lb. of sulphuric acid (in 12% solution) and run into a small excess of barium carbonate (5% paste). The barium carbonate must be free from sulphide. The pigment is dried below the temperature of formation of antimony tetroxide.—A. de W.

Carbon-black and lampblack; Process for the manufacture of —. J. M. Gerard, New York. U.S. Pat. 1,278,137, 10.9.18. Appl., 8.10.17.

THE gaseous products resulting from the incomplete combustion of a hydrocarbon, and containing 2 or 3 lb. of suspended unoxidised carbon particles per 1000 cub. ft., are caused to impinge on a cool surface until substantially 1 lb. of the said carbon particles per 1000 cub. ft. of the gaseous products is collected, the remainder of the carbon particles being electrically precipitated at a voltage ensuring collection in a finely-divided form.—A. de W.

Coating paper. U.S. Pat. 1,277,904. See V.

XIV.—INDIA-RUBBER; CUTTA-PERCHA.

PATENTS.

Indiarubber, vulcanite, and like substances; Substitutes for —. J. F. Bennett, Dronfield, and F. W. Mellowes, Sheffield. Eng. Pat. 119,878, 10.10.17. (Appl. 4998/17.)

PLASTIC masses are obtained by heating a mixture of fatty oil, sulphur, and stearin or other hard fat. The fatty oil may be replaced by mineral oil or jelly, and other ingredients such as tar, resin or pitch, lime or iron oxide, and various forms of cellulose fibre, may be introduced to modify the consistency or strength of the product. This is stated to dissolve in most of the common rubber solvents.—D. F. T.

Leather scrap or refuse; Consolidation of — together with crude or waste rubber. J. L. Watkins, London. Eng. Pat. 119,902, 16.10.17. (Appl. 14,965/17.)

IN rubber substitutes of the type composed of scrap rubber, scrap leather, new rubber, and cotton or other vegetable fibre, kapok fibre is used as the vegetable fibre. The ingredients are mixed together with oil, asbestos dust or fibre, additional fibrous material if required, a metallic oxide, and a

vulcanising agent such as caustic soda or sulphur; the resulting dough is rolled into sheets or bars and vulcanised in any suitable manner. The product has excellent stitching and flexible qualities.

—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Glue; Determination of the adhesiveness of —. M. Rudeloff. Mitt. K. Materialprüf., 1918, 36, 2—49.

The solution of the glue is applied to the planed end surfaces of two pieces of red beech wood 185 mm. long, 125 mm. broad, and 50 mm. thick, and these are placed so that the glued surfaces cross at right angles. The glue film is then allowed to dry under definite pressure, and the force required to tear the pieces of wood apart is measured by means of a suitable machine. In a series of determinations made in this way it was found that for glue solutions up to 200% of water (referred to weight of glue dried at 100° C.) the tenacity of the film decreased in proportion to the extent to which the wood was heated prior to glueing, but that in the case of solutions with 300% of water the greater degree of heating had a favourable influence. The tenacity of the glue film does not decrease in direct proportion to the rise in the amount of water. In the case of solutions with 100 to 150% of water the pressure under which the glue film is dried has no appreciable influence on the tenacity of the film, but with higher amounts of water the drying pressure has considerable influence, especially when the wood has been previously heated. The most suitable conditions for testing samples of glue by this method are the use of solutions containing 150% of water, previous heating of the pieces of wood to 40° C. in dry air, and drying of the film under a pressure of not less than 0.84 kilo. per sq. cm. Solutions containing 100 to 150% of water give concordant results by this method, which may also be used for comparison with the results obtained by determining the viscosity at 35° C. of glue solutions with 556% of water.—C. A. M.

Drilling oils, etc. Marcusson. See IIa.

PATENTS.

Tannin; Extraction of pine-bark —. L. Bruml and R. Silberberger, Klattau, Bohemia. Ger. Pat. 306,529, 22.8.16. Int. Conv., 28.6.16.

Prior to the extraction of tannin, resins are removed from the bark by a solvent boiling at about 100° C. An increased yield of tannin results.

—F. C. T.

[*Tanning agents.*] *Water-soluble condensation products of the naphthalene series; Production of* —. O. Schmidt and F. Günther, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,278,229, 10.9.18. Appl. 29.1.17.

A WATER-SOLUBLE product containing fewer sulphonie acid groups than naphthalene nuclei is obtained by condensing formaldehyde with an insoluble naphthalene hydrocarbon and a naphthalenesulphonie acid, e.g., by the interaction of formaldehyde, β -naphthalenesulphonie acid, and naphthalene in presence of sulphuric acid of non-sulphonating strength; the product is capable of precipitating glue from acid solutions.—D. F. T.

Hides and skins; Bating and deliming of — [with waste liquors from manufacture of tartaric acid]. E. Luksch, Vienna. Ger. Pat. 305,898, 2.11.16. Int. Conv., 27.5.16.

The waste liquors obtained in the manufacture of tartaric acid after precipitation of calcium tartrate form an excellent bating and deliming liquor.

—F. C. T.

Hides and skins; Tanning — by means of hydrolysed [chrome] tanning liquors. E. Kanel, Agram. Ger. Pat. 306,015, 16.10.15.

STRONGLY basic chrome solutions which deposit chromium hydroxide at ordinary temperatures can be used when cooled. In some cases it is advantageous to warm the hides after they are completely penetrated by the liquor.—F. C. T.

Leather substitute; Manufacture of a — suitable for the production of models. F. Krohmer, Pforzheim-Brötzingen, and A. Schätzle, Pforzheim. Ger. Pat. 306,104, 19.9.16. Addition to 302,194 (this J., 1918, 344A).

SUITABLE wide-meshed fabric is saturated with an oil-varnish or similar substance, and pressed together with a filling material consisting of leather dust, glue, tale or the like, and colouring matter if desired. Strips so prepared are laid in warm water at 40°–50° C. before use, until completely softened and free from air bubbles.—F. C. T.

Utilising leather scrap, etc. Eng. Pat. 119,902. See XIV.

XVI.—SOILS; FERTILISERS.

Bacterium lactis viscosum; Occurrence of — in soil. C. R. Fellers. Soil Sci., 1918, 5, 487–488.

ORGANISMS corresponding to written descriptions and laboratory cultures of *B. lactis viscosum* were isolated from two different soils, neither of which had received applications of cow dung for several years. It is probable that the soil is a natural habitat of this organism.—W. G.

Nitrogen-assimilating bacteria; Influence of reaction on —. E. B. Fred and A. Davenport. J. Agric. Res., 1918, 14, 317–336.

THE most noticeable difference in the behaviour of *Rhizobium leguminosarum* derived from different leguminous plants is that certain strains develop much more rapidly than others. To determine the effect of acid and alkali upon these bacteria and upon azotobacter, cultivations were made on mannitol solutions, the reaction of which was changed by the addition of sulphuric acid or sodium hydroxide, and the cultures incubated for four weeks at 28° C. The number of bacteria present was then determined, and the hydrogen-ion content of the cultures was measured colorimetrically. It was found that sulphuric acid in culture media is far more injurious to alfalfa bacteria than to lupin bacteria. The leguminous bacteria may be divided into the following groups as regards their sensitiveness to acid: (1) Critical, P_H 4.9, alfalfa and sweet clover; (2) P_H 4.7, garden pea, field pea, and vetch; (3) P_H 4.2, red clover and common beans; (4) P_H 3.3, soya beans and velvet beans; (5) P_H 3.15, lupins. Leguminous bacteria are more resistant to alkali than to acid, about ten times as much N/1 alkali as acid being required to produce a similar injury. No pronounced difference in sensitiveness to alkali was shown by

different leguminous bacteria. *Azotobacter* is extremely sensitive to slight changes in the reaction of the culture media. The acid limit for the growth of *azotobacter* in mannitol solution is about $N/1333.3$ and the alkaline limit about $N/1000$, or the critical P_{H} acid value is 6.5 and the alkaline value 8.6. Nodule bacteria from different leguminous plants show pronounced differences as regards the hydrogen-ion concentration of the medium. There appears to be some relationship between the degrees of resistance to acid shown by the bacteria and by the higher plant.—C. A. M.

Potash: Availability of — in some common soil-forming minerals. Effect of lime upon potash absorption by different crops. J. K. Plummer. J. Agric. Res., 1918, 14, 297–315.

The common soil-forming minerals, biotite, muscovite, orthoclase, and microcline, show little difference as regards the solubility of their contained potassium in water; but biotite and muscovite yield considerably more potassium to solutions of carbonic acid than do orthoclase and microcline. The solubility of the potassium in any of these minerals is not increased by lime in the form of calcium bicarbonate. Pot experiments have shown that oats, soya bean, rye, and cow-pea take up different amounts of potassium from these minerals. For example, the increase in the yield of the dry matter of oats following the application of biotite is four times as great as with microcline and 66% as much as with potassium sulphate, whilst the increase with muscovite is nearly twice as much as with orthoclase. Analogous results are obtained with rye. The addition of calcium carbonate does not cause any material increase in the yield of dry substance or in the amount of potassium removed from the soil by oats or rye, but when used in conjunction with biotite it causes an increase in the yield of the dry matter of soya bean by about 33%. Calcium carbonate used in association with muscovite causes a pronounced increase in the growth of the plant, and a smaller increase when used in association with orthoclase or microcline. Soya beans and cow-peas removed more potassium from soils treated with calcium carbonate in association with potassium sulphate, biotite, and muscovite, which may be attributed to the development of more favourable conditions in the soil for the growth of the plants, and not necessarily to more potassium having been dissolved. The addition of calcium carbonate does not appear to increase the solubility in $N/5$ nitric acid of potassium in soils treated with any of these minerals.—C. A. M.

Ammonium sulphate: Influence of — on the germination and the growth of barley in sand and soil cultures kept at different moisture contents and at various osmotic concentrations of the soil solution. M. I. Wolkoff. Soil Sci., 1918, 5, 421–479.

The fertilisers applied to the sand or soil were ammonium sulphate, potassium dihydrogen phosphate, calcium carbonate, magnesium sulphate, and ferrous sulphate in different proportions, and the effects of different amounts of potassium chloride, sodium chloride, sodium nitrate, calcium sulphate, aluminium sulphate, and sodium silicate added to the principal mixture were also studied. The moisture content of the sand or light sandy loam in the pots was kept constant at either 20, 40, 60, or 80% of the water-holding capacity of the sand or sandy loam used. In the germination tests two other series having moisture contents of 10 and 15% respectively were used. The moisture content of the soil had a very marked influence on the growth and development of the plants. In the sand cul-

tures the plant yield increased with the moisture content right up to the 80% series, but on the sandy loam the maximum yield of dry matter of barley was obtained in the 60% series. The plant growth either on the soil or sandy loam where the moisture content was kept at 20% of saturation was very small. With a constant moisture content the crop yields increased in the case of the sand cultures with an increase in the application of either ammonium sulphate, calcium carbonate, or potassium phosphate, the effect diminishing in the order given. There was a similar response to applications of nitrogen to the sandy loam, but not to those of lime or phosphate. The difference in plant growth at the various moisture contents is attributed either to the difference in concentration of the soil solution or to the aeration of the soil. The osmotic concentration of the soil solution following the normal application of a fertiliser is not great enough to influence plant growth if the moisture content of the soil is at its optimum (about 60% of saturation). It only becomes an important factor when the moisture content of the soil is considerably reduced. With certain nutrient solutions in the sand cultures with a moisture content of 60%, beneficial results were obtained by the additional application of magnesium sulphate and ferrous sulphate, and also by small applications of potassium chloride, sodium chloride, sodium nitrate, calcium sulphate, and sodium silicate. This beneficial effect is attributed to an improvement in the balance of the ions of the component salts in the soil solution. Aluminium sulphate under similar conditions caused some injury to the plants. A proper balance in the nutrient solution is essential for the rigidity of the straw; the "lodging" effect of applications of large amounts of nitrogenous material may be entirely subdued by modifying the proportions between the component salts in the nutritive solution in sand cultures. The germination of barley seeds is influenced by the same general agencies that affect the growth of plants, though not to the same extent. In sand, germination takes place when the moisture content is as low as 10% or as high as 80% of the water-holding capacity, but in the soils studied it would not take place when the moisture content was below 20%, and was retarded when it reached 80% of the saturation. The treatment of the sand or soil with a nutrient solution at the high moisture contents had very little, if any, effect on the germination of barley seeds.—W. G.

Potassium ammonium nitrate, a new top-dressing for sugar-beet. M. Hoffmann. Deuts. Zuckerind., 1918, 43, 149–150. Z. angew. Chem., 1918, 31, Ref., 313.

POTASSIUM ammonium nitrate prepared from ammonium nitrate and potassium chloride by the Badische Anilin und Sodafabrik has been used in some places for small experiments. It is easy to distribute over the land, and contains about 13% N, 25% K_2O , about 3–4% H_2O , and 27–30% Cl. This material can be used with perfect safety as a top-dressing. It has the advantage over ammonium nitrate, that it can be spread more uniformly and is much less hygroscopic and explosive. According to Schneidewind, potassium ammonium nitrate has exactly the same action as an equivalent amount of sodium nitrate. It is proposed to put a sodium ammonium nitrate on the market. Ammonium chloride, containing 23–25% N, has been put on the market this year, and has the same effect as the sulphate, but care must be taken in using it for plants sensitive to chlorine.—W. G.

By-product lime [Endlaugenkalk]. P. Kosmann. Tonind.-Zell., 1918, 42, 579–580.

A VERY brief summary of the various processes patented for preparing a lime fertiliser from the

waste liquors obtained in the extraction of potassium from the Stassfurt salts. Essentially they consist in treating the liquor with an excess of calcium oxide. Magnesium hydroxide and calcium chloride are formed, and these, together with excess of lime, form the principal constituents of the product. An analysis of one sample is given, which contained 9% of magnesium hydroxide, 50% of calcium hydroxide, and 34.26% of calcium chloride ($\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$).—W. G.

Plants; Cause of the poisonous action of coal-gas on —. C. Wehmer. *Z. angew. Chem.*, 1918, **31**, 205—209.

EXPERIMENTS carried out by the author prove that the injurious action of coal-gas on the growth of plants and germination of seeds (this J., 1917, 1021, 1106, 1187) is due to hydrocyanic acid which is present in minute quantity in coal-gas.—W. P. S.

Plants; Behaviour of organic compounds in —. G. Clamician and C. Ravenna. *Gaz. Chim. Ital.*, 1918, **48**, I., 253—304.

RESULTS are given of experiments on the action of various compounds on the germination and development of plants, on the oxidation of organic compounds by the agency of enzymes contained in spinach leaves and apple pulp, and on the inoculation into living maize plants of pyridine and nicotine, these bases being partly eliminated through the leaves and possibly partly transformed by the plant. (See also *J. Chem. Soc.*, Dec., 1918.)

—T. H. P.

PATENT.

Manure from house, town, and other refuse; Manufacture of —. A. D. Furse, Beckenham, Kent. Eng. Pat. 119,834, 10.5.18. (Appl., 7843/18.)

THIS invention relates to improvements in the process described in Eng. Pat. 5847 of 1913 (this J., 1913, 953). After the refuse has passed through the first disintegrator, it is spread over a drying floor or passed through an automatic drying machine, in order to reduce the number of disintegrators required for the subsequent fine pulverisation. Fluffy material is removed after the pulverisation is completed by passing the refuse over a shaking sieve.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Aldoses; Determination of — by means of iodine in alkaline solution. H. Colin and O. Liévin. *Bull. Soc. Chim.*, 1918, **23**, 403—405.

THE authors have slightly modified Bougault's method (this J., 1917, 899) and use an alkaline solution containing 35 grms. of sodium phosphate and 50 c.c. of N/1 sodium hydroxide per litre in place of the mixture of sodium carbonate and sodium bicarbonate. An excess of N/10 iodine solution is used, and the volume of alkali added is twice that of the iodine solution. The reaction is complete at the end of one hour, and the excess iodine is titrated back after making the solution just acid with sulphuric acid. Satisfactory results were obtained with the roots and rhizomes of chicory and artichokes, but the results with the leaves were somewhat uncertain.—W. G.

Potassium ammonium nitrate. Hoffmann. See XVI.

Wheat, rye, and potato starches. Unna. See XIXa.

PATENT.

Beet slices; Process and apparatus for the continuous extraction of —. H. Eberhardt, Wölfenbützel. Ger. Pat. 306,517, 5.2.16.

IN a continuous counter-current diffusion process, the suitably pre-heated slices are conveyed downwards at an adjustable rate, through a closed diffuser in which the liquid travels upwards. By heating the juice below, the upper concentrated zones of juice are prevented from sinking. The conveying mechanism for the slices in the diffuser may revolve in opposition to a rotatory movement of the juice. From the bottom of the diffuser the almost exhausted slices are conveyed for a considerable distance against the inflowing water current, to complete the extraction of sugar. In working under pressure, the slices are conveyed into and out of the diffuser through tall pipes to maintain the requisite head of liquid. The conveying mechanism in the diffuser may comprise perforated cylinders through which the slices are transported downwards by spiral conveyors, or it may comprise fixed plates and rotating scrapers or rotating plates and fixed scrapers. Fixed and rotating heating coils may be provided inside the diffuser.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Yeast growth. A. Sator. *Biochem. J.*, 1918, **12**, 248—258.

A METHOD of measuring rates of growth of yeast by direct observation under the microscope at constant temperature is described. The generation times of individual cells of a yeast growing in malt-wort at 30° C. vary within limits which are 10% on each side of the average value of 73 minutes. When old yeast cells are introduced into a fresh medium they remain quiescent for some time (lag-phase). They then start growing at the normal unrestricted rate. Yeast growth proceeds in alternate periods of apparent rest and growth. Little or no lag is observed in yeast cells grown from spores. Air is necessary for yeast growth; the cells can utilise oxygen chemically combined in the wort as well as dissolved oxygen; carbon dioxide inhibits growth. If yeast is seeded into malt-wort, the following stages of growth may be observed: the lag-phase, the logarithmic phase or period of unrestricted growth, retardation in growth due to carbon dioxide, retardation due to failure of oxygen. The latter factor is the main one which finally stops growth. By altering the conditions of seeding, aeration, temperature, etc., one or more of these stages of growth may be caused to disappear. Regarding the influence of temperature, it is found that at a temperature above that at which maximum growth occurs, some cells grow at about the maximum rate, some at lower rates, and some die. By these and similar studies it appears possible to put the problem of yeast crops on a sound mathematical basis.

—H. W. B.

Wine; New method for determining the watering of —. U. Pratolongo. *Staz. Sper. Agrar. Ital.*, 1918, **51**, 56—60. *Bull. Agric. Intell.*, 1918, **9**, 1104.

NATURAL wine forms a saturated solution of potassium bitartrate and calcium tartrate. If a wine, when treated with these two salts, dissolves further quantities, the presence of added water is indicated. Portions of the wine under examination are treated separately with excess of potassium bitartrate and calcium tartrate, respectively; the mixtures are kept at 50° to 60° C. for 30 mins., then cooled, the

undissolved salts removed, and determinations made of the two salts in the wine both before and after saturation.—W. P. S.

Enzyme action. Falk. See XII.

Antineuritic substances. Sugiura. See XX.

PATENTS.

Malt; Process for kilning —. E. Weymar, Mühlhausen, Thuringia. Ger. Pat. 306,751, 5.11.16.

MALT is subjected to the kilning (curing) temperature, not as whole corns, but in the form of grist; or the grist may be separated into husks, grits, and meal, and the process applied to some or all of the fractions. Caramel malt and colour malt may be produced in this way.—J. H. L.

Brewing [wort boiling]; Process of —. Branerz zum Wagnerbräu H. Wagner, Munich. Ger. Pat. 306,839, 29.4.17.

THE first wort from the mash is boiled by itself to a gravity of 28–35° Balling, and then diluted with later and weaker wort and boiled again. The process intensifies the malt-like flavour and aroma of the wort and is therefore especially suitable for the preparation of thin beers.—J. H. L.

XIXa.—FOODS.

Milk; Cholesterol in —. W. Denis and A. S. Minot. J. Biol. Chem., 1918, 36, 59–61.

Cow's milk contains from 0.010 to 0.018% of cholesterol; human milk, up to 0.038%. The amount probably varies with the cholesterol content of the food.—H. W. B.

Whey proteins and curd; Method for distinguishing between —. O. Lüning and W. Tönhus. Z. Unters. Nahr. Genussm., 1918, 36, 63–65.

CASEIN, or curd, dissolves in 1% ammonium oxalate solution and is re-precipitated by acetic acid, whilst whey proteins do not yield any substances which are precipitated by acetic acid from the ammonium oxalate solution. This test does not, however, afford a means of directly identifying ordinary whey proteins since casein is rarely removed completely from the whey. The products may be distinguished by determining the total soluble nitrogen: 2.5 grms. of the sample is ground in a mortar with hot 1% sodium oxalate solution, the mixture rinsed into a 250 c.c. flask with about 200 c.c. of the same solution, heated to boiling, allowed to stand for 24 hrs., then diluted to the mark, filtered, and the nitrogen determined in the filtrate. Curd yields 22 to 23% of nitrogenous substances, whilst whey proteins give from 1 to 3%. —W. P. S.

Margarine; Determination of water in — by heating in aluminium beakers. J. Prescher. Z. Unters. Nahr. Genussm., 1918, 36, 70–71.

THE usual method of determining water in margarine by heating the sample in an aluminium beaker until the water has been evaporated presents some difficulty in the case of margarine as now sold in Germany. Excessive spitting takes place probably owing to the presence of traces of soap (from the purification of the crude fats) and of potato starch; the soap appears to coat the starch

granules and the steam escapes violently. Distillation with xylene or drying on sand in the water-oven is recommended in the case of such samples.

—W. P. S.

Wheat, rye, and potato starches; Micro-colorimetric method for the identification of — in the presence of each other. E. Unna. Z. Unters. Nahr. Genussm., 1918, 36, 49–53.

TEN grms. of the flour is steeped in 3% phenol solution for 24 hrs., and a small portion is then transferred to a microscope slide and air-dried for 30 mins. It is then treated with a mixture of 1 gm. of Water Blue-Orcein solution (Water-Blue, 1, Orcein, 1, glacial acetic acid, 5, glycerol, 20, alcohol, 50, and water, 100 parts) and 6 drops of 1% eosin solution (in 60% alcohol); after 10 mins., the preparation is washed with water, treated for 20 mins. with 1% Safranine solution, again washed with water, and treated for 30 mins. with 0.5% potassium bichromate solution. The preparation is finally washed with water, alcohol, and xylene, mounted in Canada balsam, and examined under the microscope. Potato starch is coloured bright red, whilst wheat and rye starches are brownish-yellow, the rye being darker than the wheat. Gluten is coloured bright blue.—W. P. S.

Vegetables; Antiscorbutic property of desiccated and cooked —. M. H. Givens and B. Cohen. J. Biol. Chem., 1918, 36, 127–145.

RAW cabbage added to a scorbutic diet prevents the onset of scurvy in guinea pigs. Cabbage dried at 40°–50° C. retains a small proportion of its antiscorbutic quality, but heating at 75°–80° C. or cooking for 30 minutes and then drying at 65°–70° C. completely destroys the anti-scorbutic vitamin. Potatoes cooked and dried at 65°–70° C. also possess no anti-scorbutic value.—H. W. B.

Vegetables; Investigation of the methods employed for cooking — with special reference to the losses incurred. J. Dried legumes. H. Masters. Biochem. J., 1918, 12, 231–247.

BUTTER BEANS, haricot beans, and dried peas should be soaked overnight in 1% sodium bicarbonate solution, and, after straining, cooked in a 0.25% salt solution either in a steamer for 1½ hours or by boiling for about an hour. This method ensures the least loss of material and the shortest time of boiling.—H. W. B.

Banana; Nutritive value of the —. K. Sugiura and S. R. Benedict. J. Biol. Chem., 1918, 36, 171–189.

THE banana is unable to supply adequate material for the growth or maintenance of albino rats, being deficient in protein and in the water-soluble accessory substance. The addition of casein and yeast or carrot extract to the bananas renders the diet sufficient for growth and maintenance purposes. The casein in the diet cannot be satisfactorily replaced by beef protein.—H. W. B.

B. botulinus; Bacterial precipitins and the detection of — in preserved foods by the thermoprecipitation method. M. Bornand. Trav. chim. aliment. et d'hyg., 1918 9, 87–98. Bull. Agric. Intell., 1918, 9, 1113–1114.

A RABBIT was inoculated repeatedly with extracts of a culture of the *B. botulinus*, and when bled, the serum was found to have precipitating properties specific for the *B. botulinus*. Either the filtered, serum or the serum preserved with toluene could be used, the latter having the stronger action. The

precipitogen in the serum was stable on heating. Boxes of preserved beef, herrings, and peas were inoculated with the *B. botulinus*, and after five months were opened, and cultures made from the contents showed the presence of the *B. botulinus*. 5 grms. of each specimen was added to physiological salt solution and boiled in a water-bath for 5 mins. The solution was filtered and added to the prepared anti-serum, when a precipitate was formed in the case of the beef and the herrings, but not in the case of the peas.—J. H. J.

Determining aldoses. Colin and Liévin. See XVII.

Antineuritic substances. Suglura. See XX.

PATENTS.

Cereals, seeds, and flour, especially maize; Process for regenerating damaged — L. Callebaut, Sas van Gent, Holland. Eng. Pat. 110,361. 11.10.17. (Appl. 14,752/17.)

The damaged cereals are washed in water, and extracted for 60 hrs. at 50° C. with water containing dilute soda lye and sulphur dioxide, or sulphur dioxide (0.5%) alone, in order to remove deleterious substances and to sterilise the cereals. The extracted cereals are washed and rapidly dried in a vacuum.—J. H. J.

Flour or meal. J. Sleeman, Stonehouse, Gloucester. Eng. Pat. 119,923. 26.10.17. (Appl. 15,624/17.)

FRUITS or vegetables are cleaned, sliced or pulped, dried to below 12% of moisture, ground to a meal, and passed through a sieve to separate the coarser particles. The product may be mixed with wheat flour or maize malt flour. The coarse particles may be used as a cattle food. Pomace from cider and perry manufacture may be treated by this process. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 21,038 of 1892, 2981 of 1903, 26,794 of 1905, 1074 and 16,651 of 1909, 17,723 of 1913, and 8371 of 1915; this J., 1893, 942; 1909, 903; 1914, 330.)—J. H. J.

Food preparation. Mapleton's Nut Food Co., Ltd., and H. Mapleton, Liverpool. Eng. Pat. 120,018. 31.7.18. (Appl. 12,499/18.)

ALMONDS, filberts, and pea-nuts are blanched, dried at 150° F. (65.5° C.), and ground to a paste to which water is added to bring the mixture to the consistency of cream. 10% of milk powder or an equivalent of fresh milk is added, together with a pure culture of lactic acid organisms, and the mass is fermented at 60°–70° F. (15.5°–21° C.) for 20 hrs. The excess of water is then separated, and 2% of salt is kneaded in.—J. H. J.

Foodstuffs; Extraction of — from bones and other animal substances. A. Tumner, Berlin-Hohenschönhausen. Ger. Pat. 307,141. 12.10.17.

DURING the extraction of bones and other animal substances by steam in the usual manner, they are repeatedly treated with the broth, after the latter has been freed from fat, and are also subjected to mechanical pressure.—L. A. C.

XIXB.—WATER PURIFICATION; SANITATION.

Sewage purification; Importance of geological factors in — E. A. and A. E. Cooper. Biochem. J., 1918, 12. 275–281.

IS the dissolved oxygen absorption test for the standardisation of a sewage effluent, it is essential that the latter should be diluted with water

collected from the river or stream into which the effluent is discharged instead of with laboratory tap-water. The results also suggest that waters from sedimentary rocks, and those associated with the detritus of eruptive rocks, where the active chemical constituents have been or are released, may be expected to affect profoundly the biological processes of oxidation.—H. W. B.

Phosphorus; Determination of white — in mouse poisons. F. Mach and P. Lederle. Chem.-Zeit., 1918, 42, 491.

TEN grms. of the material is mixed with 5 grms. of plaster of Paris, the powdered mixture is transferred to a 200 c.c. cylinder and shaken for 1 hour with 100 c.c. of carbon bisulphide. After settling, 10 c.c. of the clear solution is withdrawn and added to 50 c.c. of saturated bromine solution. The oxidation of the phosphorus by the bromine is complete in 1 hour at the ordinary temperature, and the resulting phosphoric acid is precipitated as ammonium magnesium phosphate after the carbon bisulphide and the excess of bromine have been evaporated.—W. P. S.

PATENTS.

Sterilising apparatus. R. E. Case, South Norwalk, Conn., Assignor to The R.U.V. Co., New York. U.S. Pat. 1,277,378, 3.9.18. Appl., 13.3.16.

IS an apparatus for sterilising liquids by means of a "purifying chemical," prepared electrolytically, which is discharged continuously into the liquid as the latter flows through a conduit, the production of the "purifying chemical" is regulated automatically by, and is proportional to, the flow of liquid through the conduit.—W. E. F. P.

Sterilising liquids; Process of — L. M. Wood, Spokane, Assignor to J. R. Gunna, Kelso, Wash. U.S. Pat. 1,278,278, 10.9.18. Appl., 19.12.17.

THE liquid in its container is submitted to the action of ultra-violet rays of varying frequency from an electric lamp suspended in, and moved throughout the liquid.—J. H. J.

Air; Continuous sterilisation and purification of — [by means of ozonised water]. A. Wolff, Berlin. Ger. Pats. (A) 307,433, 15.8.16, and (B) 307,434, 25.1.17.

(A) A QUANTITY of water is circulated continuously through two towers, being pumped from the bottom of one tower to the top of the other. In each tower the water flows downwards in the form of a fine spray, and a separate current of air is pumped into the bottom of each tower, passing out at the top. The air entering one tower, the "saturation tower," has been passed previously through an ozoniser, and ozonises the water with which it comes in contact; in the other tower, the current of air is scrubbed by the spray of ozonised water and is thus sterilised and purified. If desired, the air issuing from the saturation tower, which still contains a certain proportion of ozone, may be mixed with the sterilised air. (B) In an improved form of the above apparatus, the saturation tower is omitted, ozonisation of the water being effected by leading it into one end of a pipe at the top of the sterilising tower and ozonised air into the other end of the pipe. The water enters the tower through a series of nozzles fixed on the pipe, and from the bottom of the tower is pumped back to the top through a system of pipes in which it is utilised to drive a dynamo and an air compressor, and to cool the air under treatment. Air is forced by means of the compressor through the cooler,

which it leaves by a forked pipe, part passing through an ozoniser and then to the top of the tower, where it ozonises the water, and the remainder direct to the bottom of the tower. The sterilised air leaves the tower at the top, and means are provided whereby the humidity and temperature of the air may be altered as desired. Air so treated remains free of germs and is valuable for therapeutic purposes, *e.g.*, for the treatment of open wounds, etc.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Glucosides; New synthetic — F. Mauthner. J. prakt. Chem., 1918, 97, 217–224.

TETRA-ACETOGLUCCOACETOVANILLONE, $C_{24}H_{24}O_{12}$, colourless crystals, m.pt. 156° – 157° C., obtained by the condensation of acetovanillone and acetobromoglucose by sodium hydroxide in aqueous acetone solution below 18° C., is converted by 6% barium hydroxide solution into glucoacetovanillone, $C_{15}H_{20}O_8$, needles, m.pt. 225° – 224° C. Methyl tetra-acetoglucosalicylate (tetra-acetogantherin), $C_{22}H_{26}O_{12}$, leaflets, m.pt. 154° – 155° C., methyl tetra-acetogluco-*p*-coumarate, $C_{24}H_{28}O_{12}$, m.pt. 160° – 161° C., and methyl tetra-acetoglucoferulate, $C_{25}H_{30}O_{13}$, needles, m.pt. 125° – 126° C., have been similarly prepared from methyl salicylate, *p*-coumarate, and ferulate respectively. The last two yield by hydrolysis gluco-*p*-coumaric acid, $C_{15}H_{18}O_8$, needles, m.pt. 194° – 195° C., and glucoferulic acid, $C_{16}H_{20}O_9$, needles, m.pt. 186° – 187° C. (See also J. Chem. Soc., Dec., 1918.)—C. S.

Santonin; Oxidation of — by means of organic peracids. G. Cusmano. Gaz. Chim. Ital., 1918, 48, I., 248–253.

OXIDATION of santonin by means of perbenzoic or peracetic acid yields isoartemisin or δ -oxysantonin and ϵ -oxysantonin. Treatment of the latter with concentrated hydrochloric acid in the cold yields a new chlorosantonin, $C_{15}H_{17}O_4Cl$. (See also J. Chem. Soc., 1918, i., 434.)—T. H. P.

Antitoxic sera; Concentration of — by the salting-out of the heat-denatured serum proteins with sodium chloride. A. Homer. Biochem. J., 1918, 12, 190–209.

THE concentration of anti-toxic sera can be successfully conducted by regulation of the heat-denaturation of the serum proteins, followed by a direct treatment of the heated sera with brine and salt. The end products thus obtained are clear and easily filterable, but they are more deeply coloured than those furnished by the Ranzhaf and Homer methods. Moreover, they contain a higher percentage of serum proteins and have a lower degree of concentration of the antitoxin. (See also this J., 1917, 734; 1918, 107 A.)—H. W. B.

Antineuritic substances from carrots and yeast; Preparation of — K. Sugiura. J. Biol. Chem., 1918, 36, 191–196.

ALCOHOLIC and aqueous extracts of yeast and of carrots cure polyneuritis in pigeons. A colourless crystalline substance of considerable curative value can be obtained from dried yeast by dissolving in salt solution and subjecting it to per-crystallisation through a collodion bag by Kober's method (this J., 1917, 1038; see further J. Chem. Soc., 1918, i., 532).—H. W. B.

Uric acid in blood; New volumetric method for the determination of — L. J. Curman and A. Lehrman. J. Biol. Chem., 1918, 36, 157–170.

THE method consists in removing the proteins from the blood by coagulation, precipitating the uric acid in the filtrate by nickel acetate in the presence of sodium carbonate, and estimating the uric acid in the precipitate by means of a standard solution of iodine. (See further J. Chem. Soc., Dec., 1918.)—H. W. B.

Lactic acid; Thiophen test for — A colour test for aldehydes. Biochemical colour tests. 1. W. R. Fearon. Biochem. J., 1918, 12, 179–183.

THE thiophen reaction for lactic acid is due to the production of acetaldehyde from the lactic acid, which interacts with the thiophen in the presence of excess of sulphuric acid to give the cherry-red colour. This discovery forms the basis for the following general reaction for aldehydes: A couple of drops of a 0.2% alcoholic solution of thiophen are mixed with 5 c.c. of concentrated sulphuric acid and then a drop of a weak solution of an aldehyde is added. A red colour develops and spreads through the acid. On adding a few drops of water, the colour is discharged, but can be reproduced by adding more sulphuric acid. The test can detect 1 part of formaldehyde in 100,000; substituted aldehydes such as chloral, *p*-hydroxybenzaldehyde, etc. also give a positive reaction. The presence of aldehydes in moist ether can be demonstrated by this test, which is important because ether is frequently used in the extraction of lactic acid, prior to estimation. (See also J. Chem. Soc., Dec., 1918.)—H. W. B.

Iodoform; Alteration of — alone or in solution, in direct light. E. Comanducci and G. Meduri. Gaz. Chim. Ital., 1918, 48, I., 238–247.

THE action of direct sunlight on solutions of iodoform in 19 different organic solvents, kept in sealed vessels almost filled with the solutions, has been studied. The solution (1%) in olive oil remains unchanged after a year. In absence of solvent, iodoform undergoes very little decomposition under the above conditions.—T. H. P.

Nitriles; Direct transformation of acid chlorides into — by catalysis. A. Mailhe. Bull. Soc. Chim., 1918, 23, 380–381.

ACID chlorides may be converted directly into the corresponding nitriles by passing their vapours mixed with ammonia over alumina at 490° – 500° C. Excellent results were obtained with benzoyl, isovaleryl, isobutyryl, and propionyl chlorides.—W. G.

Esters; Influence of temperature and constitution on the velocity of hydrolysis of — by hydrogen ion catalysis. F. Bürki. Helv. Chim. Acta, 1918, 1, 231–250.

THE hydrolysis of several esters has been studied in the presence of hydrochloric acid, nitric acid, and sulphuric acid respectively at 25° , 30° and 40° C. The catalytic action increases rapidly with rising temperature, most in the case of hydrochloric acid and least with sulphuric acid. The substitution of one chlorine in the acid of the ester reduces the velocity of hydrolysis to $\frac{1}{2}$ of its initial value, whilst two chlorine atoms reduce it only to $\frac{1}{3}$ of the original value. An unsaturated group in the alcohol of the ester has no effect on the rate of hydrolysis, whilst an unsaturated group in the acid considerably reduces the velocity. (See also J. Chem. Soc., Dec., 1918.)—J. F. S.

Esterification in aqueous solution. A. Purgotti. *Gaz. Chim. Ital.*, 1918, 48, II., 54—62.

ONLY slight esterification takes place between alcohol and acetic acid in aqueous solution, addition of sodium chloride appreciably increasing the proportion of ester formed. Acids catalyse the reaction in proportion to their dissociation, and a similar action is exerted by mono- and di-hydric phenols; gallic and tannic acids and trihydric phenols retard the esterification.—T. H. P.

PATENTS.

Chloroform; Manufacture of —. S. Utheim. Christiania, Norway. Eng. Pat. 116,094, 13.5.18. (Appl. 8026/18.) Int. Conv., 25.5.17.

A 10% AQUEOUS acetaldehyde solution is added gradually to a mixture of 100 grms. of bleaching powder and 1 litre of water, heated at 60°–80° C., and contained in a vessel provided with a stirrer. The aldehyde is instantaneously and quantitatively converted into chloroform which distils off and is collected. The temperature of the mixture may be maintained at 60°–80° C. by regulating the supply of aldehyde solution. Other hypochlorites may be used in place of bleaching powder and the solution should contain about 10% of active chlorine.—W. P. S.

Tobacco; Process for treating —. H. H. Albertsen, Roskilde, Denmark. Eng. Pat. 119,959, 2.1.18. (Appl. 138/18.)

INFERIOR tobaccos are soaked in hot water or in a steam bath and the sap containing the nicotine is removed by pressing or by other means. After subsequent drying the tobacco leaves are immersed in a decoction of stalks or dust derived from tobaccos of greater value; after the required quantity of "nicotine" has been absorbed, the tobacco is again dried. In this way it is possible to convert European tobaccos into the equivalent of the finer over-seas products.—D. P. T.

p-[Hydr]oxyphenylarsinic acid; Manufacture of —. W. W. Myddleton, Runcorn. Eng. Pat. 119,964, 10.1.18. (Appl. 573/18.)

INSTEAD of removing the *p*-hydroxyphenylarsinic acid from the crude reaction product obtained in any known manner, by extraction with acetone, the crude acid is treated in warm aqueous solution with a suitable neutral salt, such as sodium acetate, which is capable of being decomposed by the *p*-hydroxyphenylarsinic acid, the resulting sodium *p*-hydroxyphenylarsinate being easily obtained in a pure crystalline condition by cooling the solution after previous filtration and concentration; the salt may be purified further by recrystallisation.—D. P. T.

Line-tannin compound; Production of a — slightly soluble in dilute acids. Knoll und Co., Ludwigshafen. Ger. Pat. 307,857, 14.4.16. Addition to 306,979 (this J., 1918, 672A).

A SOLUTION of tannic acid is heated with calcium hydroxide until a basic calcium tannate of a sufficiently low degree of solubility is produced.

—A. B. S.

XXI. PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Colour photography. W. V. D. Kelley, Brooklyn, N.Y., Assignor to Prizma, Inc. U.S. Pat. 1,278,161, 10.9.17. Appl., 7.2.16.

A TWO-COLOUR process is employed in which the first colour image is obtained by converting a

metallic, e.g. silver, image into a dye image through the medium of a metal-dye compound, and the second colour image is obtained by re-sensitising the film, e.g. with bichromate, and, after exposure under the second negative, treating with a solution of a dye which is absorbed in a degree varying with the hardness of the film.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Smokeless powder; Quantitative determination of acetone in —. A. Pieroni. *Atti R. Accad. Lincei*, 1918, 27, II., 52—57.

THE discordant results obtained in the determination of acetone are due to the difficulty of converting acetone quantitatively into iodoform, to the ease with which the latter is attacked by excess of alkali, to the loss of iodine owing to secondary reactions, and to the volatility of iodoform. The following procedure gives satisfactory results with smokeless powders which contain between 3 and 0.25% of acetone. From 35 to 50 grms. of the powder in lumps is weighed to the nearest 0.01 gm. and ground in a special apparatus in which the powder is kept washed by a stream of distilled water so as to prevent evaporation of the solvent. The ground mass, together with the water, is either collected in a large beaker or passed directly through a funnel into a distillation flask of about 2 litres capacity; 100 c.c. of dilute sulphuric acid (1:1) is then added to prevent emulsification of the distillate. Steam is passed into the flask and the latter also heated with a burner. The distillate passes from the condenser into a bulbous adapter reaching almost to the bottom of a test-tube which is full of water and is situated in a conical flask. From the latter unabsorbed gases pass through a washer, which retains any traces of acetone still unabsorbed. When 250–300 c.c. of distillate, i.e. rather more than one-half of the volume of liquid originally in the distilling flask, has been collected, the adapter is removed and a little fresh distillate collected in a test-tube and tested for acetone by means of potash and iodine. When acetone ceases to distil over, the whole of the liquid in the collecting flasks, together with the washings of these and of the adapter, is made up to 500 c.c. in a measuring flask. Exactly 100 c.c. of the mixed solution is pipetted into a cylinder of about 300 c.c. capacity with a ground stopper. From two burettes are then run in a solution containing 112 grms. of potassium hydroxide per litre and another containing 257 grms. of iodine and 330 grms. of potassium iodide per litre; the two solutions should drop at the same time and at the rate of about 20 drops per minute, the cylinder being kept shaken meanwhile. From time to time the addition is stopped for a time until the iodoform settles and the supernatant yellow liquid clarifies; if further addition of the potash and iodine solutions produces no turbidity, the transformation of the acetone is complete. After a rest of a few minutes, such excess of sodium chloride is added that 10 grms. or so remains undissolved, 50 c.c. of ether kept over sodium being then added, the cylinder tightly closed and the liquid shaken energetically three or four times. As soon as the two layers have separated completely, 25 c.c. of the ethereal iodoform solution is pipetted into 25 c.c. of saturated alcoholic caustic potash solution; the volume of alcoholic potash to be used varies with the volume of iodine used in the reaction with the acetone, the former being in general double the latter. The liquid is diluted with alcohol until clear, heated in a water-bath to evaporate the ether, and boiled for 15 minutes; the alcohol is then distilled off, the

liquid diluted with water, cooled, and acidified with dilute nitric acid, and the potassium iodide formed determined volumetrically by Volhard's method. If a is the number of c.c. of $N/10$ silver nitrate solution used and b the weight in grams of the powder taken, the percentage of acetone in the latter will be $2a/b$.—T. H. P.

Cap compositions; Analysis of —. Marqueyrol and P. Lorient. Bull. Soc. Chim., 1918, 23, 401—403.

THE powder is first extracted with ether, to dissolve the organic components (trinitrotoluene, picric acid, etc.). The residue is filtered off, and the filtrate is evaporated at the ordinary temperature, the soluble material being finally dried at 60°C ., weighed, and then characterised. The residue is extracted with a few c.c. of cold water, filtered, and the insoluble matter washed with a very little water. The aqueous extract is evaporated to dryness, the residue weighed, and its composition (chlorates, nitrates, etc.) determined. The residue insoluble in ether and water is extracted with 10 c.c. of a 5% solution of potassium cyanide, being left in contact with the solution for two hours. The solution is filtered, the residue being washed, first with more of the solution and then with water, and the whole of the filtrate and washings is submitted to electrolysis. The mercury of any mercury fulminate in the original powder is deposited, washed, and weighed. The residue from this last extraction is mixed with a little water and 1 c.c. of glacial acetic acid and distilled into a 5% solution of silver nitrate. If the original powder contained any lead azide, a precipitate of silver azide is formed and is filtered off, washed with water, alcohol, and ether, and dried and weighed. By this process the approximate quantitative composition of the powder is obtained.—W. G.

Trinitrotoluene and tetranitromethane; Fatal cases of poisoning by —. Fischer. Zentralbl. Gewerbehyg., 1917, 205. Chem.-Zeit., 1918, 42, Rep., 165.

THE history of seven fatal cases of poisoning by trinitrotoluene is described, and the author expresses the opinion that the actual cause of the poisoning was the tetranitromethane present, in greater or smaller quantity, in the trinitrotoluene. Evidence in favour of this view is brought forward.

XXIII.—ANALYSIS.

Alkalimetry; Errors in — due to the carbon dioxide content of distilled water. G. Bruhns. Z. anal. Chem., 1918, 57, 257—277.

DISTILLED water absorbs carbon dioxide from the atmosphere and this dissolved carbon dioxide has a marked influence on the results obtained in alkalimetric titrations if such water is used for the preparation of the standard solutions. The standard acid and alkali solutions themselves absorb carbon dioxide.—W. P. S.

Iodolannic reagent [for determination of alkalinity]. D. E. Tsakalotos and D. Palmas. Bull. Soc. Chim., 1918, 23, 391—400.

THE reagent is a mixture of 1 c.c. of $N/10$ -iodine solution with 1 c.c. of 1% tannin solution, and by means of it the alkalinity of very dilute alkaline solutions may be determined as follows. The alkaline solution is added from a burette to the 2 c.c. of reagent, with stirring, until a definite red

colour appears. From this point the alkaline solution is run in gradually, and after each addition a drop of the mixture is tested on starch paper. The end-point is reached when a blue colour is no longer formed on the test-paper. Knowing the volume of alkaline solution used, its alkalinity may be calculated by means of data given in a table in the original. By means of this reagent exact results may be obtained for alkaline solutions at a dilution of $N/10,000$ to $N/40,000$.—W. G.

Platinum; Replacement of — in apparatus for electrolysis. P. Nicolardot and J. Boudet. Bull. Soc. Chim., 1918, 23, 387—391.

ELECTRODES made of alloys of gold and platinum containing from 12.5—25% Pt were found to vary in weight during electrolysis of certain solutions. The authors recommend the use of an alloy of gold, silver, and copper in the proportions of 920 : 50 : 30, the electrodes being coated with a thin layer of platinum (0.005 grm. per sq. cm.).—W. G.

Magneto-chemistry; Applications of — to analysis. II. A. Quartaroli. Gaz. Chim. Ital., 1918, 48, I., 65—78.

THE method previously described (this J., 1916, 278) for the determination of certain magnetic salts in solution may be advantageously replaced by the following procedure, which admits of the use of magnetic fields not of exceptionally great intensity and requires no special apparatus. In a magnetic field obtained by the use of horizontal poles of frusto-conical form with circular ends, is inserted a small tube about 8 mm. in internal diameter. This tube contains a standard dilute ferric chloride solution slightly acidified with hydrochloric acid, the surface of the liquid corresponding with the lower point where the poles begin to diverge. The solution of the ferric salt to be determined, best coloured with an ordinary indicator, is pipetted carefully on to the top of the standard solution so as not to mix with it. When the magnet is excited, the upper solution, if the more concentrated, bulges out into the lower and in some cases a globule becomes detached and remains suspended in the lower layer. The upper solution is then gradually diluted with successive diminishing quantities of water until a just perceptible bulge appears within about a minute, the concentrations of the two solutions then corresponding. Descriptions are given of the modes of applying this method to: the estimation of iron, either alone or in presence of manganese or chromium; the estimation of chromium, manganese, nickel, and cobalt; volumetric analysis with permanganate; volumetric analysis with bichromate and analysis of mixtures of chromic salts and chromates; the analysis of solutions containing ferrocyanides, ferricyanides, thiocyanates, and organic matter. (See also J. Chem. Soc., Dec., 1918.)—T. H. P.

Potassium; Simplification of the method of estimation of —. W. Hüttner. Kali, 1918, 12, 178—179. Z. angew. Chem., 1918, 31, Ref., 310.

A WEIGHED quantity of the potassium salt (in the form of sulphate) is dissolved in cold water in a graduated flask and sufficient barium bromide, in concentrated aqueous solution, is added, the whole being well shaken and the flask filled up to the mark. The precipitate is filtered off and 10 c.c. of the filtrate is precipitated with perchloric acid in a glass basin. The results obtained by this method are in agreement with those obtained when barium chloride is used. If it is necessary to use heat for the solution of the potassium salt, the

author recommends the use of hydrobromic rather than hydrochloric acid in order to avoid the formation of barium chloride, which is insoluble in alcohol and might cause an error in the result.

—W. G.

Magnesium; Gravimetric determination of —. L. W. Winkler. *Z. angew. Chem.*, 1918, **31**, 211–212.

Precipitation of magnesium as $MgNH_4PO_4 \cdot 6H_2O$ and weighing it in this form is recommended: 100 c.c. of the solution, containing not more than 0.05 grm. of magnesium, is treated with 3 grms. of ammonium chloride, heated at about $90^\circ C.$, 10 c.c. of 10% ammonia is added, and then 10 c.c. of 10% sodium phosphate solution is run in while the mixture is stirred. After 24 hrs., the precipitate is collected on a cotton-wool filter, washed with ammonia, then with methyl alcohol, dried for 24 hrs. over calcium chloride, and weighed. The filter is washed previously with methyl alcohol and dried over calcium chloride. Potassium and sodium chlorides if present in moderate quantity (not more than 5% in the solution) do not interfere, but if large quantities are present the magnesium must be determined by the ordinary method as pyrophosphate. The addition of a suitable quantity of ammonium chloride (at least 3 grms.) is necessary to ensure complete precipitation of the magnesium.

—W. P. S.

Copper; Gravimetric determination of — by means of sodium nitroprusside, and the separation of copper from mercury. E. Votoček and J. Pazourek. *Chem.-Zeit.*, 1918, **42**, 475–476.

A cupric salt is mixed with an excess of sodium nitroprusside solution acidified with dilute sulphuric acid, the mixture diluted to 170 c.c., shaken for 2 to 4 hours, the precipitated cupric nitroprusside then collected on a tared filter, washed with water, dried at $110^\circ C.$, and weighed; it contains 22.75% Cu. The yield averages 99.2% of the amount of copper present. To determine copper in the presence of mercury, the copper is precipitated as cupric nitroprusside as described, but in this case a known excess of $N/10$ sodium chloride solution is also added to prevent precipitation of mercuric nitroprusside. The mercury in the filtrate from the copper precipitate is then precipitated as sulphide or determined by titrating the excess of sodium chloride with standard mercury solution. The presence of lead and bismuth does not interfere with the determination of copper, but tin salts should not be present.

—W. P. S.

Copper; Determination of — by means of potassium thiocyanate and potassium iodide. G. Bruhns. *Centralbl. Zuckerind.*, 1918, **26**, 354–356. *Z. angew. Chem.*, 1918, **31**, Ref., 510.

In the estimation of copper in Fehling's solution, by means of potassium thiocyanate and potassium iodide, by the method previously described (see this J., 1918, 445 v), considerable errors may occur if the acidified copper solution is allowed to stand for some time after the addition of potassium thiocyanate before being titrated with thio-sulphate solution. These errors are due to the gradual formation of insoluble cuprous thiocyanate, the copper thus precipitated being removed from the iodometric estimation.—W. G.

Copper; Iodometric estimation of —. I. M. Kolt-hoff. *Pharm. Weekblad*, 1918, **55**, 1328–1346.

A SUMMARY of the literature of the iodine method of estimating copper, and an account of the results obtained by varying the experimental conditions.

—A. J. W.

Cadmium and nickel; Alkali iodides as reagents for —. A. Agrestini. *Gaz. Chim. Ital.*, 1918, **48**, 11., 30–34.

ADDITION of potassium iodide solution of 20–30% concentration to a distinctly ammoniacal solution of a cadmium salt produces a heavy white precipitate composed of microscopic regular octahedra having the formula, $Cd(NH_4)_2I_2$; under similar conditions, no precipitate is obtained with ammoniacal copper solutions. Strongly ammoniacal solutions of nickel salts, however, yield a precipitate of $Ni(NH_4)_2I_2$, which consists of bluish-violet, microscopic octahedra; if the concentration of the nickel is low, the precipitate is formed only after shaking the liquid and scratching the side of the vessel with a glass rod. Both these precipitates undergo hydrolysis. Since cobalt also gives a precipitate with this reagent, it should be removed by means of Vogel's reaction before the solution is tested for nickel. To this end the solution is treated with concentrated ammonium thiocyanate solution and the whole shaken with a mixture of 1 vol. of amyl alcohol and 10 vols. of ether. By means of a separating funnel the aqueous liquid is separated from the supernatant blue alcohol-ether solution of ammonium cobalto-thiocyanate and further extracted with two fresh portions of the alcohol-ether mixture. The residual greenish aqueous liquid is treated with ammonia and potassium iodide solution as before. Potassium iodide is not so sensitive a reagent for nickel as dimethylglyoxime, but the latter is costly and at present not easily procurable.—T. H. P.

PATENT.

Burettes and the like. J. W. Towers, Widnes,
and J. Harger, Gateacre, Lanes. Eng. Pat.
119,580, 11.12.17. (Appl. 18,331/17.)

A DEVICE for use in place of taps on burettes, etc., is described. The bore of the exit tube of the burette is blocked and above and below the block the bore is extended laterally through the wall of the tube. A rubber tube is slipped over the tube to close the two openings thus formed. By pinching the rubber tube the openings may be uncovered and a channel made for the liquid in the burette to flow from the upper part of the bore to the lower and so be discharged. If desired, a piece of glass rod may be placed in the rubber tube; if this rod is moved over the two holes by pressing it with the finger, a channel is formed for the liquid. When the rod is moved off the holes, the latter are closed by the rubber tube pressing on them.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Apeldoornsche Machinefabriek. Refrigerating,
and refrigerating apparatus. 19,084 and 19,106.
Nov. 20 and 21. (Holland, 20.11.17 and S.4.18.)

Archer. Kilns. 18,610. Nov. 13.

Brettell. Heat-insulating coverings. 19,204.
Nov. 22.

Calvert. Apparatus for catalytic reactions.
18,632. Nov. 13.

Candy. 19,096. See XIX.

Chandler, and South Metropolitan Gas Co. Gas-
heated furnaces. 18,983. Nov. 19.

Commin. Mechanical agitators. 18,402. Nov. 11.

Cuming. Utilising vacuum principle for insula-
tion of high and low temperatures. 18,948. Nov. 19.

Cuming. Conversion of wood waste, vegetable
and like substances and their utilisation as insulat-
ing material. 18,949. Nov. 19.

Drake, and Drakes, Ltd. Regenerative furnaces.
18,405. Nov. 11.

Dufton. Still heads. 18,415. Nov. 11.

Fiechter. Filtering apparatus for gases etc.
18,637. Nov. 14.

Boiler settings; Measuring temperature of gases in —. H. Krelsinger and J. F. Barkley. U.S. Bureau of Mines, Bull. 145, 1918. 72 pages.

THE errors in measuring the temperature of hot gases are chiefly due to radiation from the instrument, variation of the temperature at different points in a cross-section of the path of the gases, and fluctuation of the temperature at the point of measurement. The radiation error is the most significant and in some cases may amount to several hundred degrees Fahrenheit. A thermocouple having the hot junction inclosed in a protecting tube reads lower than an unprotected couple, but of course the latter can only be used where it will not be subject to contamination. The smaller the wires at the hot junction of the couple the more accurate is the determined temperature. The true temperature can be obtained approximately by using three or more couples of various sizes and determining from these readings, by extrapolation, the theoretical indication of a couple of zero diameter. The nature and extent of the radiation error was determined in this manner for the burning gases in settings of Babcock and Wilcox, Heine, and Stirling water-tube boilers. By screening the thermo-couple so that hot gases pass on both sides of the screen, the radiation error can be considerably reduced and results can be obtained which are only about 20° F. (11° C.) too low. For temperatures of flue gases the copper-constantan couple can be more advantageously used than the platinum-platinum rhodium couple because its E.M.F. is about four times that of the latter. Although easily contaminated, the relative cheapness of copper-constantan couples enables them to be readily replaced. Full instructions are given in the report for making, standardising, and using this couple in conjunction with a portable potentiometer. The theoretical aspect of the radiation error is treated in much detail, due attention being paid to emissivity, size of couple, and the effect of the temperature and velocity of the gas stream.—T. F. E. R.

PATENTS.

Drying liquids; Machines for —. T. Blom and A. Gledde, Wärmland, Sweden. Eng. Pat. 110,753, 22.10.17. (Appl. 15,347/17.) Int. Conv. 23.10.16.

THE liquid to be dried is fed from a hopper, which may be in the form of a closed chamber subjected to a vacuum and serving for the preliminary concentration of the liquid, on to the surface of an annular horizontal plate which forms the upper side of an annular chamber rotating within a casing about a hollow vertical axis through which a suitable heating medium passes into and out of the chamber. Heated air from the lower part of the casing is caused to circulate over the surface of the plate in a direction opposite to that in which it is rotated. A scraper removes the dried material from the plate at a point just before it passes beneath the feed hopper.—W. H. C.

Drying fruit, vegetables and other materials; Apparatus for use in —. H. A. Price and J. Sugg, London. Eng. Pat. 120,283, 20.11.17. (Appl. 17,118/17.)

THE fruit or other material is supported on perforated trays spaced apart one above the other in a drying chamber. Air is heated by a burner mounted on a swing door in a chamber placed below the drying chamber, and separated from it by an inclined baffle-plate. Inclined adjustable

baffles are arranged between the trays so that the heated air passes under, over, and through the material on the trays.—W. H. C.

Dryer. F. G. Sargent, Westford, Mass., Assignor to C. G. Sargent's Sons Corporation, Graniteville, Mass. U.S. Pat. 1,279,165, 17.9.18. Appl. 20.12.17.

SUPERPOSED reciprocating conveyors mounted in a frame are arranged in a casing so as to leave a considerable space between the walls of the casing and the top, bottom, and one side of the series. The opposite edges of the conveyors are slightly spaced from the adjacent side wall of the casing. At each side of each conveyor a vertical partition extends upwards, a space being left between it and the bottom of the next partition for the circulation of air. A fan is arranged in the bottom of the casing to circulate air upwards through the conveyors and downwards through the wider side space back to the fan. If a conveyor is clogged, the air circulates round it through the spaces at the sides.—W. F. F.

Gas dryer. J. Kennedy, Pittsburg, Pa. U.S. Pat. 1,280,043, 24.9.18. Appl. 16.4.18.

THE apparatus comprises a vertical casing with a gas inlet at the top and a hopper-shaped lower portion provided with an outlet for dirt and water. A helical baffle extends through the casing and at its lower end terminates at a point above the hopper. A gas outlet pipe has its open end just above the hopper, and extends obliquely upwards through one side of the casing at a point between the lower end of the baffle and the hopper.—J. H. P.

Evaporator; Multiple effect —. W. S. Herriot, Glasgow. From N. Deerr, Brooklyn, N.Y., U.S.A. Eng. Pat. 120,276, 12.11.17. (Appl. 16,544/17.)

IN a multiple-effect evaporator with vertical tubes and rectangular tube-plates, the calandria is designed so that the outlets for the uncondensable gases and condensed water respectively are at the side of the vapour chamber opposite to that at which the vapour enters. The chamber is divided into two parts by a downtake of rectangular cross-section in the middle, extending almost the whole length of the chamber. Uncondensed gases escape through vertical perforated tubes connected to a manifold, and condensed water flows through other vertical tubes connected to another manifold. The liquid to be evaporated is introduced and withdrawn through perforated horizontal tubes disposed, one on each side of the downtake, beneath the lower tube-plate. Circulation of the liquid up through the tubes and down through the downtake is promoted by curved deflecting plates beneath the lower tube-plate.—J. H. P.

Evaporating and crystallising apparatus especially adapted for obtaining large crystals. Soc. d'Exploit. de Proc. Evaporatoires, Système Prache et Bouillon, Paris. Eng. Pat. 112,943, 21.1.18. (Appl. 1171/18.) Int. Conv., 23.1.17.

THE solution to be evaporated is charged into the vessel, 1, 2, 3, 4, up to the level, 18, and is maintained at this level by the addition of more solution as the solvent evaporates. The propelling screw, 14, situated in the end of the pipe, 12, forces the liquid from the space, 13, between the wall of the upper part of the vessel and the partition, 6, downwards through the tubes of the heater, 9. The liquid is here heated to the temperature at which it would boil under atmospheric pressure, but

ebullition is prevented by the pressure due to the propelling screw and the head of liquid. The heated liquid passes back by the pipe, 16, 17, into the narrow cylindrical portion, 3, of the vessel, and passes upwards, circulating in the direction shown by the arrows. When the rising liquid reaches the level of the conical portion, 2, it commences to boil owing to the diminution of pressure

and deposits fine crystals. The vapour escapes from the top of the chamber, 1, and the fine crystals are maintained in suspension by the upward current of liquid until they have grown sufficiently large for their weight to overcome the upward thrust. They then fall through the liquid into the collecting chamber, 4, and are removed from time to time through the valve, 5.—W. H. C.

Furnaces; Apparatus for maintaining proportional delivery of gas and air to gas-fired — J. and G. Keith, London. Eng. Pat. 120,976, 20.10.17. (Appl. 15,253/17.)

The air supply to a gas-fired furnace passes through the control valve, J, and constricted member, D, to the pipe, B. The diaphragms, E, F, are connected by a rod, K, and operate a butterfly-valve, L, in the gas inlet, C'. A partition, N, provided with a manually operated valve, H, divides the chamber, G, into two compartments each containing a diaphragm. Tubes, e, f, connect the spaces at the back of the diaphragms, E, F, to the high and low pressure sides of the constriction, D. Any modification in the rate of flow of the air in the

pipe, B, varies the relative pressures on the backs of the diaphragms and moves the rod, K, to operate the valve, L, so that the proportion of gas passing through to the pipe, C, and air passing through the pipe, B, remains constant. To avoid any excessive pressure difference on the two sides of either diaphragm, a modification is described in which the two sides of one diaphragm are exposed to the two air pressures only, and the two sides of the

other diaphragm to gas pressures only. Improved sensitiveness may be obtained by keeping the stroke of the diaphragms as short as possible by the provision of a relay valve for the gas supply, operated by the movement of the diaphragms.

—W. F. F.

Recuperator furnace. W. H. Stubblebine, Allentown, Pa. U.S. Pat. 1,279,932, 24.9.18. Appl. 19.10.17.

The furnace comprises a fire chamber, a working chamber, a preheating chamber, and an auxiliary recuperator chamber. Flues connect the preheating chamber with the fire chamber, and a passageway leads from the preheating chamber and communicates with flues in the roof of the fire chamber. Coils connected with an air supply pipe are mounted in the preheating chamber and have nozzles opening into the latter. A blast pipe communicates with the fire chamber. The auxiliary recuperating chamber is provided with ports communicating with the working chamber. Air-heating coils within the auxiliary recuperating chamber have nozzles leading into passageways in the walls of the working chamber, which are provided with ports opening into the working chamber.

—J. H. P.

Furnaces for generating heat for steam raising or other suitable purposes. F. E. Whitham, Sowerby Bridge, Yorks. Eng. Pat. 120,274, 9.11.17. (Appl. 16,409/17.)

A MIXTURE of powdered fuel and air is burnt in a combustion chamber, not shown, provided with grate-bars leading to a shoot, V, to receive any solid residue. The combustion chamber discharges into the bottom of a helical flue, D, surrounding a central chamber, C, and leading through a tangential passage, E, to a circular chamber, F, and thence by the passage, J, to a boiler or the like. The flue, D, is constructed of blocks having a number of inverted V-shaped bridges, K, forming

pockets between them, which are provided with outlets, L, into the chamber, C. Incombustible material in the gases passing through the flue, D, falls into the pockets and is discharged into the chamber, C. The chamber, F, is provided with

peripheral pockets which receive solid material from the rotating gases and discharge it into the hopper, G, and thence into the chamber, C. The furnace is mounted on a feed-water tank, N, which is divided into compartments through which the water is circulated. The water is heated by the hot incombustible material passing through the hopper, M, and shoot, V.—W. F. F.

Gases and liquids; Apparatus for bringing — into intimate contact. R. S. Hilton and J. H. Willis, Birmingham. Eng. Pat. 120,304, 4.1.18. (Appl. 218/18.)

SEVERAL superposed chambers, separated by conical partitions, each have a central gas passage covered by a hood provided with louvres through which the gas passes upwards to the next chamber. The liquid which collects in the annular space between each cone and the side wall of the chamber is circulated by a pump or injector to a sprayer in the gas passage of the partition next above, and just below the hood, so that it returns to the same chamber and is thus concentrated by continuous absorption of gas. All the circulating pumps may be mounted on the same vertical driving shaft, and the sprayers may be mounted on horizontal guide rods and connected to valve-boxes, so that any one may be withdrawn without affecting the working of the others. A perforated grid carrying scrubbing material may be arranged just over the gas passage in each partition.—W. F. F.

Gases and vapours; Purification of —. H. Zschocke, Kaiserslautern. Ger. Pat. 307,890, 22.2.16.

THE invention comprises a series of centrifugal machines with gas passages from one to the other. Each centrifugal machine contains two sets of rotating vanes and one set of stationary vanes. Prior to entering the first centrifugal, the gas is subjected to a fine spray of water, whereby the heavier impurities are removed. The gas is likewise subjected to a water spray in the centrifugal. After passage through a centrifugal, the gas expands into a free space prior to passage into the next centrifugal, which is of larger diameter and in which the vanes rotate at a higher speed. In a modification in which the centrifugal machines are all of the same diameter, successive passage-ways for the gas from one centrifugal to the next are of smaller cross-section than the preceding passage-way, so that the velocity of the gas is augmented as the gas passes through the apparatus.

—J. S. G. T.

Filter. J. M. Wilmer, Lancaster, Pa. U.S. Pat. 1,279,063, 17.9.18. Appl., 5.5.16.

AN endless conveyor belt of filtering material passes over a series of supporting rollers having a larger diameter at the middle, so that the belt is arched in passing over the rollers and liquid is drained towards the edges.—W. F. F.

Filter cakes; Method of washing —. A. I. Genter, Assignor to United Filters Corporation, Salt Lake City, Utah. U.S. Pat. 1,280,439, 1.10.18. Appl., 15.9.17.

IN a method of washing a filter-cake *in situ* by means of a current of atomised fluid, there is interposed between the source of fluid supply and the filter-cake an agent to retard the impinging velocity of the current against the cake.—J. H. P.

Replacing a liquid containing suspended solids by another liquid; Process of —. G. Moore, Joplin, Mo. U.S. Pat. 1,279,573, 24.9.18. Appl., 12.6.13.

SUSPENDED solids present in a strong solution are allowed to settle on to the surface of a travelling band or the like, which is then removed to a weaker solution. The settled solids are stirred up and again allowed to settle on to the supporting surface, which is then removed to a still weaker solution or to water and the process repeated.—W. H. C.

Refrigerating-machine. D. I. Davis, Chicago, Ill. U.S. Pat. 1,280,101, 24.9.18. Appl., 15.6.16. Renewed 8.4.18.

THE gaseous refrigerant after receiving an initial compression in a low-stage compressor is mixed in the connecting main with some of the condensed liquid from the condenser and then passes to a high-stage compressor where the final compression is effected.—W. H. C.

Centrifugal process. T. A. Bryson, Troy, N.J., Assignor to Tollhurst Machine Works. U.S. Pat. 1,280,153, 1.10.18. Appl., 21.3.18.

FINELY divided impervious material in suspension in a liquid is separated by centrifugal action so as to form a gradually thickening outer layer of the material and simultaneously the separated liquid is drained off from just within the impervious layer, *e.g.*, in the apparatus described in U.S. Pat. 1,273,817 (this J., 1918, 614 A).—J. H. P.

Catalyst and method of making same. A. Schwarzman, Assignor to Kellogg Products, Inc., Buffalo, N.Y. U.S. Pat. 1,280,314, 1.10.18. Appl., 13.8.17.

A NON-SLIMING decolorising catalyst is obtained by impregnating a porous powder having high adsorbing power for colouring matters, e.g. fullers' earth, with a nickel salt, precipitating the nickel in the pores of the material with a solution containing a dissolved nitrogenous organic colloid, e.g. dissolved wool, drying, and reducing the nickel to the colloidal metallic state. The material should be free from alkali-soluble substances.—A. de W.

Gases and vapours: Method of and apparatus for treating — electrically. W. T. Hoofnagle, Glen Ridge, N.J., Assignor to Electro-Chemical Products Co., New York. U.S. Pat. 1,280,471, 1.10.18. Appl., 23.11.17.

The reaction chamber is divided by a horizontal diaphragm provided with openings, over which tubular electrodes with internal heat-radiating ribs are mounted. The opposing electrodes project upwards into the tubes and are also provided with heat-radiating ribs. An electrical condenser is connected across the terminals of the source of current, and the electrodes are all connected in series, with a spark-gap between one condenser terminal and one of the electrodes. The gas to be treated passes at a pressure substantially below atmospheric from one compartment to the other through the tubular electrodes, thus passing in parallel between the electrodes. The discharges between the electrodes are of short duration and high current density, and the gas is passed through at a rate proportional to the frequency of the discharge.—W. F. F.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Combustion in fuel beds of hand-fired furnaces: Low-rate —. H. Kreisinger, C. E. Augustine, and S. H. Katz, U.S. Bureau of Mines. Tech. Paper 139, 1918. 52 pages.

TESTS have been made with the object of studying the processes of combustion in the fuel bed of hand-fired furnaces such as the American stove. These stoves burn coal at rates below 20 lb. per sq. ft. per hour. Furnaces burning coal at much higher rates, such as those of locomotive boilers, have been reported upon in Tech. Paper 137 (see this J., 1917, 919). The experimental furnace consisted of a steel cylinder, 30 in. high, lined with $4\frac{1}{2}$ " fire-bricks, and having a grate area of 1 sq. ft. The

air spaces in the grate were $\frac{1}{4}$ " across and constituted about 60% of the total grate area. Arrangements were made for sampling the gases at different heights in the fuel bed, the latter being either 6 or 12 in. deep. The fuel was charged in at the top and the products escaped by the same opening. The fuels tested were Pittsburgh coal (bituminous), anthracite, metallurgical coke, and semi-coke, broken into pieces which would pass through a screen with $1\frac{1}{2}$ " holes and remain on one with 1" holes. The gases arising from the fuel bed contained 16 to 30% of combustible gases. The following gas analyses and temperatures are typical of those tests in which bituminous coal was used. The fuel bed was 12" deep and was replenished with small quantities at short intervals.

Height above grate at which sample was taken	CO ₂	Unsat. hydrocarbons	O ₂	CO	CH ₄	H ₂	N ₂	Temp °F

7 lb. of air was necessary to gasify 1 lb. of coal, this ratio remaining constant over a wide range. An additional 7 lb. of air was required to burn the combustible products and was supplied above the fuel bed; the quantity required temporarily increased during the evolution of coal distillation products. It was found practically impossible to keep the fuel bed burning when the air supply to the grate was cut off.—T. F. E. R

Calorimeter installation; A convenient multiple-unit —. J. D. Davis and E. L. Wallace, U.S. Bureau of Mines, Tech. Paper 91, 1918. 48 pages.

AN installation of bomb calorimeters intended primarily for the determination of the calorific values of samples of coal is described. The objects aimed at in the installation are facility of operation, compactness, durability, and higher accuracy than that of the usual commercial calorimeter. The bomb consists of a gold-plated cylindrical Monel-metal shell of about 600 c.c. capacity, and is sealed to its base by a one-eighth turn with a wrench. The sealing device comprises a steel receiving nut and lock and a gasket of electricians' solder, and is an adaptation of the principle used in breech locks of cannon. Six calorimeter units are mounted in a bath, the temperature of which is maintained constant to $\pm 0.02^\circ\text{C}$. by means of a regulator operating one or other of two relays. The water supplied to the calorimeter is stored in a large tank and is kept constant to 0.1°C . by means of ice water, the flow of which to the tank is controlled by a thermo-regulator. A measured volume of this water is supplied to the calorimeter by means of a pipette immersed in the tank at constant temperature. Platinum thermometers of fundamental interval about 10 ohms are employed in the calorimeter and by means of a special switch, one bridge and galvanometer can be used with three calorimeter outfits. The resistance bridges are of special construction and read to 0.00005 ohm. The thermometers are calibrated at the ice and steam points, and at the transition point of Na_2SO_4 (32.384°C). It is recommended that the water equivalent of the calorimeter be determined by standardisation with pure substances (such as

sucrose) supplied by the Bureau of Standards. A comparison of results obtained by this method with those obtained electrically showed agreement to 1 grm. in the value of the water equivalent. The radiation correction is obtained from the results of combustion of different weights of standard substance, and a radiation correction curve is plotted from such results. The time necessary for an observation is about 8 minutes, and 35 determinations of calorific value per day, with a possible error of about 3 B.Th.U., can be made.—J. S. G. T.

Coal gas; Liquid purification of, and simultaneous recovery of sulphur and ammonia from —. P. Parrish. Southern District Assoc. Gas Eng. and Managers, Nov. 11, 1918. Gas J., 1918, 144, 413—420.

Liquid purification is a continuous process which aims chiefly at the removal of carbon dioxide and hydrogen sulphide from crude coal gas (freed from tar) by the introduction of sufficient ammonia to combine with them, and the subsequent removal by washing with water of the ammonium salts and excess ammonia. The cycle of operations involves purification of the crude gas, dissociation of the crude liquor containing the ammonium salts with removal of the waste gases (H_2S , CO_2 , etc.), recovery of the ammonia from the purified liquor for use over again, and use of the hydrogen sulphide in the waste gases for sulphuric acid manufacture or the production of sulphur in a Claus kiln. After leaving the tar scrubbers a typical coal gas contains (per ton of coal carbonised) 10.21 to 13 lb. H_2S ; 0.56 to 0.74 lb. CS_2 ; approx. 1.67 lb. HCN, and approx. 30.6 lb. CO_2 . The ammonia necessary to combine with these impurities is theoretically 38.08 lb., i.e. about 5 times the quantity normally present in the gas. The author advises the use of seven times that normally present. Every means must be taken to cut down ammonia loss, which is the *bête noire* of the process. This can be done by avoiding excessive pumping and fixing ammonia traps for the displaced air in storage tanks, also by covering stored liquor with oil. The gas washing is preferably effected in washers in which splashes are fixed, arranged on the cascade principle; pumping operations are thereby reduced. The crude liquor from the washers is decomposed with steam in a dissociator still and the hydrogen sulphide, carbon dioxide, etc., with about one-fifth of the ammonia, are driven off. About 65% of the ammonia in these gases is recovered for sale and the remainder removed and added to the crude liquor. The ammonia for sale represents that which would be normally extracted from the gas. The ammonia-free mixture of hydrogen sulphide, carbon dioxide, etc. contains not more than 20% H_2S and is burnt in a special Claus kiln, sulphur being recovered. The purified ammonia liquor leaving the dissociator still passes into an ordinary ammonia-recovery still. From data it is deduced that the equivalent of 80,417 gallons of 1.39% ammonia (8 oz. liquor) would have to be distilled daily for a works carbonising 250 tons of coal per day and using the liquid purification process. By working the dissociator under a pressure up to 3 or more atm., greater concentrations of ammonia can be used (up to 6% NH_3) and consequently the liquor to be distilled could be reduced to something like 19,000 gallons in the above case. Under correct conditions the process can be conducted with an overall efficiency of the complete purification plant of 93% of the theoretical. Many diagrams and recommendations concerning size and design of suitable stills, etc. are given, and the paper concludes with a brief criticism of the Burkheliser process, which aims at the production of ammonium sulphate from coal gas without using sulphuric acid.

—T. F. E. R.

Gas-meters; Report on the corrosion of dry —. J. G. Taplay. Life of Gas-Meters Research Committee of Inst. of Gas Eng., 1918. [Advance proof.]

Liquor removed from a dry gas meter was examined and found to consist of three fractions: (1) An oily fraction composed of 94.5% of unsaturated hydrocarbons with resins and naphthalene, 5% of pyridine bases, and 0.5% of paraffins. (2) An aqueous part containing pyridine bases, ferrous and ferric sulphate, ferric thiocyanate, ammonium thiocyanate, and leather substance in a dissolved state (compare Lessing, this J., 1916, 824; Lamb this J., 1916, 989). (3) A solid portion consisting principally of leather substance (91%) together with smaller amounts of iron oxide, sulphates of iron, tin, and zinc, and some sulphur. The effect of each of these substances and of various mixtures of them upon tinned sheet iron, and upon dressed and undressed leather was ascertained, the materials being subjected to the influence of solutions of the various substances for a period of 4 months. In like manner the effects of sulphur dioxide, carbon bisulphide, ammonia, and a mixture of carbon bisulphide and ammonia were ascertained. It was found that practically all the substances exercised a deleterious effect upon some or all of the materials employed. The action of the various salts is given in detail. Benzol was found to retard the action of a moist mixture of carbon bisulphide and ammonia upon meter materials. In many meters which failed to register correctly the fault was attributed to the presence of a resinous material on the valve. The error of registration of the meters was considerably reduced by spraying the insides of the meters with "solar oil" distillate. A further advantage is achieved by such spraying in that corrosion of the metal parts of the meter is prevented. Suggestions are made as to the possible origin of some of the substances found in the liquor abstracted from the meters.—J. S. G. T.

Aromatic hydrocarbons; Formation of — from natural gas condensate. J. G. Davidson. J. Ind. Eng. Chem., 1918, 10, 901—910.

NATURAL gas condensate containing chiefly ethane and propane with small quantities of butane and pentane has been subjected to "cracking" at various temperatures and pressures in the presence of metals. The products of the reaction are both gaseous and liquid, the latter being of a tarry nature and containing aromatic hydrocarbons. The experiments show that most metals are without effect on the conversion of paraffin hydrocarbons into aromatic hydrocarbons. Nickel, iron, and cobalt are negative catalysts for this reaction, but they accelerate the decomposition of paraffin hydrocarbons into carbon and hydrogen. A temperature of 550°C . is the most favourable for the production of liquid tar, and the formation of complex aromatic substances increases with the temperature. Increase of pressure inhibits the formation of tar, whilst diminished pressure increases the yield of unsaturated substances but also decreases the actual yield of tar. Butadiene has been isolated in fairly large amounts from the unsaturated compounds produced in the thermal decomposition of the natural gas condensate. Acetylene added to the natural gas condensate is without action in the formation of aromatic hydrocarbons. Tar containing aromatic substances has been produced from the "cracking" of a mixture of butadiene and ethylene. The most probable reaction for the formation of aromatic substances from natural gas condensates is:

from bituminous coal. Katz. See III.

Oxidation of carbon monoxide. Hofmann. See VII.

Hydrogen phosphide in hydrogen. Soyer. See VII.

PATENTS.

Coke ovens or analogous devices; Multiple regenerators for —. D. Bagley, London. Eng. Pat. 120,079, 22.10.17. (Appl. 15,346/17.)

To prevent short-circuiting of the gases in coke-oven regenerators, the latter are divided into several vertical compartments. The waste gases travel downwards through these compartments into a collecting flue connected at one end with the main waste gas flue. In order that the chimney shall exert an equal pull on each compartment, the opening into the collecting flue is larger the further the compartment is from the waste gas flue. On reversing the gas streams the secondary air is admitted through an intake flue at the end of the regenerator—this flue thus acting as a heat insulator—and enters a horizontal chamber which feeds the regenerator compartments. This chamber gradually tapers towards the other end to ensure uniform distribution of the air.—T. F. E. R.

Coking apparatus. F. Pribyl, Wilmette, Ill. U.S. Pat. 1,279,757, 24.9.18. Appl., 4.11.13. Renewed 17.12.17.

A closed chamber is provided with two parallel vertical partitions extending upwards from the floor about two-thirds of the height of the chamber, and dividing the lower part into three similar compartments. The partitions are provided with openings near their upper edges. Fuel is delivered into the upper portion of the chamber so as to fall into all the compartments, and the central compartment is provided with a grate just below the openings in the partitions, to which air is admitted to burn the fuel and generate producer gas. The hot gas passes through the openings in the partitions, and then through the fuel in the side compartments to distil this fuel. The gas and distillate pass out through openings in the walls below the level of the partition openings, and the coked material is continuously removed at any desired rate from the bottom of these compartments without admission of air or escape of gas.—W. F. F.

Chamber ovens; Continuously operated — for the manufacture of coke and gas. J. Lütz, Essen-Bredency. Ger. Pat. 307,987, 22.6.16.

The invention comprises a coking oven of annular cross-section, in the interior and around the circumference of which chambers are arranged for the collection and passage of gas. These gas chambers are kept cool by means of water tubes. The gas-collecting chambers are provided with outlets for high-grade gas at their upper part and for low-grade gas at their lower part.—J. S. G. T.

Combustion; Process of —. B. Valjean, Santa Ana, Cal. U.S. Pat. 1,280,596, 1.10.18. Appl. 12.7.16.

A NON-EXPLOSIVE poor mixture of gas and air is mixed with a non-explosive rich mixture of gas and air in such regulated proportions that the resulting combustible mixture burns with any desired type of flame from luminous to non-luminous.—W. F. F.

Power gas; Manufacture of — and the recovery of hydrocarbon oils. F. W. Chamier, H. J. Craig, and J. F. L. Moeller, London. Eng. Pat. 120,051, 21.12.16. (Appl. 18,335/16.)

A GENERATOR for the production of power gas is divided by a horizontal partition into two chambers. Coal is fed through a hopper into the upper chamber and is heated to 450°–650° C. by means of a mixture of steam and a portion of the gas generated in the lower chamber, introduced either through a perforated grate or through pipes. The coke formed is dropped intermittently into the lower chamber, into the bottom of which steam is admitted. The gas generated in each chamber is drawn off at the top, that from the upper chamber being treated for the removal of hydrocarbons, tar, etc., and that from the lower chamber, after a portion has been drawn off for injection into the upper chamber, passing through an apparatus in which it is utilised to produce the necessary steam and then into the final scrubbing tower together with the first portion of gas. The horizontal partition may be dispensed with, a portion of the gas from the lower chamber being allowed to rise directly into the upper cooler chamber, into which steam is injected.

—L. A. C.

Hydrocarbons; Formation of — having low boiling points from hydrocarbons having high boiling points. D. T. Day, Washington, D.C., F. MacDonald, Casper, Wyo., and R. B. Day, Swarthmore, Pa., U.S.A. Eng. Pat. 113,264, 16.11.17. (Appl. 16,898/17.) Int. Conv., 2.2.17.

A HORIZONTAL combustion chamber of metal lined with firebrick is connected with a vertical cracking chamber similar in construction to the combustion chamber. The oil under treatment is injected, together with steam, into the lower end of the cracking chamber, in which it comes in contact with the products of combustion generated in the first chamber, and the vapours are led off at the top to a condenser. Carbon deposited in the cracking chamber may be removed without interruption of the process by admitting an excess of air into the combustion chamber. The temperature employed in the chamber varies from 700° F. (about 370° C.) to 3000° F. (about 1650° C.), and pressures up to 609 lb. per sq. in. may be used.—L. A. C.

Hydrocarbon materials; Treatment of —. R. B. Day, Swarthmore, Pa., and D. T. Day, Washington, D.C. U.S. Pat. 1,280,179, 1.10.18. Appl. 28.9.17.

THE vapours generated in the cracking apparatus described in Eng. Pat. 113,264 of 1917 (preceding) are bubbled through a body of oil in a suitable container, thus preheating the oil and vaporising the lighter portions. The combined vapours are washed in a scrubbing tower with oil, which is afterwards passed to the preheater and cracking chamber.

—L. A. C.

Hydrocarbon materials [gasoline]; Treatment and refining of —. D. T. Day, Washington, D.C., and R. B. Day, Swarthmore, Pa., U.S.A. Eng. Pat. 119,441, 16.11.17. (Appl. 16,900/17.) Int. Conv., 28.9.17.

IN order to purify gasoline prepared as described in Eng. Pat. 113,264 and U.S. Pat. 1,280,179 (preceding), the temperature at the outlet end of the scrubbing tower is maintained at 190° C., all material condensing above that temperature being returned for further treatment. The vapour leaving the top of the tower passes through a condenser and the condensed gasoline is washed successively with sulphuric acid, water, and caustic soda solution by passing it upwards through tanks containing these reagents.—L. A. C.

Hydrocarbons [of low boiling point]: Apparatus for producing — [from hydrocarbons of high boiling point]. R. B. Day, Swarthmore, Pa., U.S.A. Eng. Pat. 120,230, 27.9.17. (Appl. 12,954/17.)

PREHEATED oil and water are pumped together into the upper end of a cracking tube provided with a number of coils situated in a chamber heated from 600° F. (about 320° C.) to 2000° F. (about 1100° C.). At the lower and hotter end of the tube there is a catalyst of nickel-chromium steel in the form of a woven net. The cracked vapours are led off through two condensers, in the first of which the cooling medium is the oil under treatment, which is thus preheated, while in the second water is used. The cracking tubes are arranged in a battery of six, each being supplied by means of a separate pump. An air pump is also connected with the top of each cracking tube in order to blow out the tube when necessary and remove deposits of carbon. A temperature of 1100° F. (about 590° C.) and a pressure of 150 lb. per sq. in. in the cracking tubes are stated to give excellent results.—L. A. C.

Hydrocarbon products; Extraction of — from shales and coal. D. T. Day, Washington, D.C., Assignor to V. L. Reed, Denver, Colo. U.S. Pat. 1,280,178, 1.10.18. Appl., 28.9.17.

SHALE or coal is subjected before distillation to the solvent action of an acid together with the vapours obtained by the destructive distillation of previously treated material.—L. A. C.

[*Mineral*] *oil refining [by distillation].* S. Brickman, Oklahoma, Okla. U.S. Pat. 1,279,506, 24.9.18. Appl., 3.9.17.

A CYLINDRICAL casing, spaced from the sides and top of a fireproof chamber, is provided with a number of partitions slightly inclined to the vertical, which are joined at their upper and lower edges so as to form a number of oil receptacles, the space above the receptacles forming a vapour-blending chamber. Oil is supplied to the receptacles, which are heated by means arranged between the receptacles and the bottom of the casing, an additional heating means being provided on the exterior of the casing. A flat superheater is disposed horizontally between the top of the casing and the top of the outer chamber, and an inlet from the vapour-blending space to the superheater and an outlet from the latter are also provided.—B. N.

Oils; Process for cleaning waste [lubricating] —. Patentierte Oelreinigungs-Fabrik A.-G., Budapest. Ger. Pat. 305,942, 11.10.16. Int. Conv., 2.5.16.

THE dirty oil is mixed with solid absorbent substances which are unaffected by oil and by water, added preferably in the form of a powder, so as to produce a pasty mass which is then subjected to compression. Suitable substances are sawdust, shavings, and the like, also cotton and tow.

—J. F. B.

Asphalts; Process for the manufacture of artificial —. R. Blum, Berlin-Grünewald. Ger. Pat. 307,961, 19.1.18.

INSTEAD of the usual asphalt materials, bituminous minerals are employed, particularly alum ore (alum earth), in combination with other known materials. The composition is used instead of tars or pitches, together with limestone for stamped asphalt, and on account of its high content of sulphur it shows some similarity to natural Trinidad asphalt.

—J. F. B.

Petroleum and other hydrocarbons; Method for treating — to produce hydrocarbons having lower boiling points. C. P. Dubbs, Wilmette, Ill., U.S.A. Eng. Pat. 112,010, 31.10.17. (Appl. 15,868/17.) Int. Conv., 27.11.16.

Distillation or carbonisation of coal and cannel; Apparatus for the —. J. T. Key, Ashbourne. Eng. Pat. 120,130, 14.12.17. (Appl. 18,578/17.)

A NUMBER of retorts in which coal or cannel is carbonised are connected with a mixing chamber provided with a series of perforated grids. When the process of carbonisation of the coal in the retort is completed, steam is introduced by a series of jets into the incandescent retort and passes through the coke into the mixing chamber. The gas from contiguous retorts entering the mixing chamber is thus subjected to the influence of this steam and a separation of the heavier impurities in the gas is effected.—J. S. G. T.

Distillation of carbonaceous substances; Destructive —. S. N. Wellington, London. Eng. Pat. 120,223, 30.7.17. (Appl. 10,973/17.)

Tar gas and vapour produced by the low temperature distillation of carbonaceous substances is cooled and passed through a tar extractor to remove tar, and is then passed through a heat exchanger in which it is heated by means of producer gas. A form of heat exchanger consisting of a series of vertical tubes enclosed in a casing is more particularly described. The gas passes downwards through the tubes in one half of the casing and upwards in the remaining tubes. The heating gases circulate in the casing in counter-current to the gas to be heated. The gas thus reheated is passed direct to a saturator to recover its ammonia.

—J. S. G. T.

Distillation of carbonaceous substances. E. R. Sutcliffe, Leigh, Assignor to Pure Coal Briquettes, Ltd., Cardiff. U.S. Pat. 1,279,172, 17.9.18. Appl., 12.4.15.

A CONTINUOUS process of carbonisation is carried out in a series of ovens so connected that the heat

necessary for the distillation of the charge in an oven is obtained by the combustion of gas which has been preheated by passage through another oven of the series. The charges in the several ovens are distilled in succession, and the hot gases pass through other ovens of the series, thereby heating the charge in such ovens.—J. S. G. T.

Cooling of hot residues from distillation processes. B. E. D. Kilburn, London. From Sulzer Frères, Soc. Anon., Winterthur, Switzerland. Eng. Pat. 120,329, 7.3.18. (Appl. 3997/18.)

The residual material from the distillation process, e.g., coke, is discharged into a series of water-jacketed receptacles. The water jackets are all connected with a suitable steam generator, and are surrounded with air chambers furnished with baffles. Air is circulated by means of a blower through the closed circuit consisting of the receptacle containing the coke and the air chambers, whereby the heat of the coke is transferred to the water in the jackets. The rate of circulation of the air can be varied and the direction of the circulation reversed.—J. S. G. T.

Electric [incandescence] lamp. J. A. Orange, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,279,415, 17.9.18. Appl., 12.9.14.

An electric lamp comprises an envelope filled with an inert gas, such as argon, at a pressure of about 150 to 200 mm. of mercury. Tungsten electrodes, of about 40 "mils." diameter and separated by a space of about 2 to 10 "mils.," are so proportioned in shape and mass as to be adapted for heating to incandescence by an arc operating between the electrodes, "at a lighting efficiency materially higher than one watt per candle power." The current-carrying conductors for the electrodes have a diameter of about 20 "mils.," but adjacent to the electrodes have a cross section equal to a diameter of 4 to 8 "mils."—B. N.

Ionic discharges [for light projection apparatus]: Method of controlling and apparatus for producing — D. F. Comstock, Brookline, Assignor to Kalmus, Comstock, and Wescott, Inc., Boston, Mass. U.S. Pat. 1,279,990, 24.9.18. Appl., 14.11.16.

III.—TAR AND TAR PRODUCTS.

Tars distilled from bituminous coal in hand-fired furnaces. S. H. Katz. U.S. Bureau of Mines, Tech. Paper 195, 1918, 20 pages.

THE quantity and composition of the tar produced in two types of hand-fired furnaces were determined. The one furnace had a grate area of about 1 sq. ft., the other a grate area of about 30 sq. ft. A fuel bed of 6 in. depth was maintained. The air supply was measured. Various rates of firing were employed. Samples of gas were withdrawn by water-cooled sampling tubes inserted radially at various points below, above, and at the surface of the fuel bed. The tar and soot contained in the samples of gas were retained by an alundum thimble containing asbestos, and were extracted with benzol in a Soxhlet apparatus. The tar was collected over a period of months before sufficient was obtained for experimental purposes. The main conclusions are as follows: Qualitatively, the tars obtained were much the same as Jones and Wheeler's "primary volatile matter" (this J., 1914, 192). When coal is added to fires in uniform quantities and at short regular intervals, the

greatest quantity of tar in the gases is at the surface of the bed. At a point 1 ft. above the bed of coal burning in a large hot furnace at moderately rapid rates, practically all tar had disappeared. Naphthalene and anthracene were absent from the tars collected. The tar that escapes burning is decomposed to soot and fixed gases, and such decomposition occurs in less than 0.1 sec.—J. S. G. T.

s-Chlorobenzenedisulphonic acid and some of its derivatives. S. C. J. Olivier. Rec. Trav. Chim. Pays-Bas, 1918, 37, 307—314.

1-Chlorobenzene-3.5-disulphonic acid, decomposing at 100° C., is obtained by heating chlorobenzene with five times its volume of fuming sulphuric acid containing 20% of sulphur trioxide at 300° C. for six hours. It yields a dichloride, m.pt., 105.5°—106° C., which when heated in a sealed tube with phosphorus pentachloride for four hours at 200°—210° C. yields s-trichlorobenzene. 1-Chlorobenzene-2.4-disulphonic acid is obtained by diazotising 2.4-disulphanilic acid in hydrochloric acid solution and decomposing the product with copper.—W. G.

Diphenylamine; Nitro-derivatives of — H. Ryan and T. Glover. Proc. Roy. Irish Acad., 1918, 34 [B], 97—105.

CONSIDERABLE discrepancies appear in the literature of the nitrodiphenylamines. With the object of removing these, the authors have prepared a series of substances by synthetic methods, that due to Goldberg (Ger. Pat. 185,663), in which aromatic amines are coupled with the halogen derivatives of aromatic nitro-compounds in nitrobenzene solution in the presence of potassium carbonate and cuprous iodide, being chiefly used. The following compounds are described: *p*-nitrodiphenylamine, m.pt. 133°—134° C., which, contrary to Goldberg's statement (*loc. cit.*), yields a colourless solution in concentrated sulphuric acid; *m*-nitrodiphenylaminosamine, colourless, acicular crystals, m.pt. 89°—90° C.; 2.4-dinitrodiphenylaminosamine, pale yellow prisms, m.pt. 149°—151° C. (by the action of isoamyl nitrite on a cold solution of 2.4-dinitrodiphenylamine in glacial acetic acid; at a slightly higher temperature, 2.4.2'.4'-tetranitrodiphenylamine slowly separates); 3.4'-dinitrodiphenylamine, pale yellow crystals, m.pt. 210°—212° C. after softening at 205° C.; 2.4.6-trinitrodiphenylamine, scarlet red prisms, m.pt. 178° C.; 2.4.3'-trinitrodiphenylamine, brown platy crystals, m.pt. 193°—194° C.; 2.4.3'-trinitro-5-methyldiphenylamine, dark yellow prisms, m.pt. 199° C. (slight decomp.); 2.4.4'-trinitro-5-methyldiphenylamine, straw-coloured, prismatic needles, m.pt. 210° C. (slight decomp.); 2.6.3'-trinitro-3-methyldiphenylamine (?), prismatic needles, m.pt. 199° C. (decomp.); 2.4.2'.4'-tetranitrodiphenylamine, brownish prisms, m.pt. 199°—200° C.; 2.4.6.3'-tetranitrodiphenylamine, short yellow prisms, m.pt. 210° C. (corr.); 2.4.6.4'-tetranitrodiphenylamine, golden yellow prisms, m.pt. 222° C. *m*-Nitrodiphenylaminosamine is converted by nitric acid in glacial acetic acid solution into trinitrodiphenylaminosamine, yellow prismatic needles, m.pt. 184°—185° C. (decomp.) after softening at about 179° C. 2.4.3'-Trinitrodiphenylamine yields tetranitrodiphenylamine, yellow crystals, m.pt. 190° C., when treated with isoamyl nitrite. Under similar circumstances, perylaniline gives two compounds one of which, m.pt. 236° C., is probably 2.4.6.2'.4'.6'-hexanitrodiphenylamine, whilst the other, m.pt. 193°—194° C., appears to be 2.4.6.2'.4'-pentanitrodiphenylamine. —H. W.

Aromatic hydrocarbons. Davidson. See 11 A.

PATENTS.

Sulphonation of [volatile] hydrocarbons and hydrocarbon derivatives. C. R. Downs, Cliffside, N.J., Assignor to The Barrett Co. U.S. Pats. (A) 1,279,295 and (B) 1,279,296, 17.9.18. Appl., 5.1.18.

(A) BENZENE, or other volatile hydrocarbon or hydrocarbon derivative, is treated with sufficient sulphuric acid to form the disulphonic acid, first at a low temperature and atmospheric pressure, whereby the non-volatile benzenemonosulphonic acid is formed, and then at the temperature necessary for the formation of the disulphonic acid (below 260° C.) and under a pressure sufficiently reduced to remove the water of reaction and maintain the acid at the strength required for the completion of the reaction.

(B) Benzene is introduced progressively into a body of sulphonating acid maintained at the sulphonating temperature, i.e., above the boiling point of benzene, thereby effecting intimate contact of benzene vapour with the acid. The reaction mixture, as in (A), is subjected to a reduced pressure.

TOLUENE is heated with dry bleaching powder without the addition of an acid or other substance for decomposing the bleaching powder.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

[Azo] dyes derived from benzidine-sulphone; Synthesis of some new substantive — H. Ryan, J. Algar, and P. O'Connell. Proc. Roy. Irish Acad., 1918, 34 [B], 85–96.

A SERIES of dyes of the benzidine type has been prepared by coupling hydroxy- and amino-compounds with the tetrazo-derivative of benzidine-sulphone-disulphonic acid.

The dyes have been isolated in the form of pure sodium salts; they act as direct dyes towards cotton and the colours are unaffected by washing. Products have been obtained with the following substances, the shade obtained on cotton being placed within brackets: naphthionic acid, dark-blue, amorphous powder (purple); β -naphthylamine, reddish amorphous powder (violet-red); α -naphthylamine, dark-red powder (navy blue); salicylic acid, reddish-brown powder (orange); "R" acid, reddish-blue powder (violet-red); "G" acid, reddish amorphous powder (pink); "H" acid, dark-blue powder (light blue); β -naphthol-6-monosulphonic acid, dark-bluish amorphous powder (light purple); catechol, dark-bluish powder (light brown); resorcinol, dark-bluish powder (amaroon); quinol, brownish powder (buff); pyrogallol, chocolate-brown powder (buff); gallic acid, dark-brown powder (light brown); sulphanilic acid, orange-red amorphous powder (canary yellow); dimethylaniline, dark-bluish powder (deep purple).—H. W.

Alizarin; Action of potassium ferrieyanide on — in alkaline solution and the constitution of salts of hydroxyanthraquinones. R. Scholl and A. Zinke. Ber., 1918, 51, 1419–1435.

ALIZARIN is oxidised to 2-hydroxy-1,4-naphthoquinone-3-vinylglyoxylic acid, $\text{HO.C}_6\text{H}_3\text{O}_2\text{CH:CH.CO.CO}_2\text{H}$, yellow leaflets, m.pt. about 230° C. (decomp., darkening above 150° C.), by an alkaline solution of potassium ferrieyanide at the ordinary temperature. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Anthraquinone-fluorenone series; Rearrangement reactions in the —. A. Schaarschmidt and J. Herzenberg. Ber., 1918, 51, 1230–1237.

ANTHRAQUINONE-2,1-fluorenone is converted into anthraquinone-2,3-fluorenone by fusion with potassium hydroxide at 220°–230° C. and treatment of the product with concentrated sulphuric acid. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Curcumin; Synthesis of — V. Lampe. Ber., 1918, 51, 1347–1355.

THE condensation of ethyl sodioacetoacetate and carbomethoxyferuloyl chloride yields ethyl α -carbomethoxyferuloylacetate, $\text{CO}_2\text{CH}_3\text{O.C}_6\text{H}_3\text{[OCH(CH:CH.CO.CH(CO.CH}_3\text{).CO}_2\text{C}_2\text{H}_5]}$, from which, by the successive processes of hydrolysis, condensation with carbomethoxyferuloyl chloride, and hydrolysis, are successively obtained carbomethoxyferuloylacetone, dicarbomethoxydiferuloylacetone (not isolated), dicarbomethoxydiferuloylmethane, and diferuloylmethane, the last-named substance being identical with natural curcumin, which thus has the constitution $\text{CH}_3\text{[CO.CH:CH.C}_6\text{H}_3\text{[OH].[OCH}_3\text{)]}_2$ suggested by Milobedzka, Kostanecki, and Lampe in 1910 (this J., 1910, 1002; see also J. Chem. Soc., Jan., 1919).

—C. S.

pp'-Dihydroxy- and p-hydroxy-dicinnamylmethane; Syntheses of — V. Lampe and M. Godlewska. Ber., 1918, 51, 1355–1360.

THE syntheses follow the same course as that of curcumin (see preceding abstract). Ethyl α -p-carbomethoxycinnamoylacetate, $\text{CO}_2\text{CH}_3\text{O.C}_6\text{H}_4\text{CH:CH.CO.CH(CO.CH}_3\text{).CO}_2\text{C}_2\text{H}_5$, p-carbomethoxycinnamoylacetone, p-hydroxycinnamoylacetone, pp'-dicarbomethoxydicinnamoylmethane, pp'-dihydroxydicinnamoylmethane, and p-hydroxydicinnamoylmethane are described. The last two compounds are compared with curcumin with respect to their dyeing action on unmordanted cotton and to the change of colour produced by boric acid. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Isobrazilein and certain related anhydropyranol salts; Synthesis of — I. H. G. Crabtree and R. Robinson. Chem. Soc. Trans., 1918, 113, 859–880.

DIHYDROBUTEIN trimethyl ether (2-hydroxy-4-methoxyphenyl β -3,4-dimethoxyphenylethyl ketone), colourless prisms, m.pt. 84° C., obtained by reducing a solution of veratrylidene-paeanol in acetic acid at 70°–80° C. by hydrogen and palladium chloride, was converted into isobrazilein ferriehloride trimethyl ether by boiling with zinc chloride and anhydrous formic acid and treating the cooled solution with dilute hydrochloric acid and an excess of concentrated ferric chloride solution.

Appendix I. [R. Robinson and M. R. Turner]. The preparation of 7-methoxy-2-phenyl-1,4-benzopyranol anhydrochloride, orange needles, m.pt. 102°–103° C. (decomp.), and of 7-methoxy-2,4-diphenyl-1,4-benzopyranol, m.pt. 55°–57° C., is described.

Appendix II. [J. A. Prescott]. The preparation is described of 7-hydroxy-4,3-indeno-1,2-benzopyrone, colourless needles, darkening at about 230° C. and becoming blue at 280° C. This is the first compound to be synthesised the molecule of which contains the brazillin and hæmatoxylin skeleton.—C. S.

PATENTS.

Dye [of the Sulphur Black type] and process of making same. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,279,307, 17.9.18. Appl., 26.6.16.

DYESTUFFS of the Sulphur Black type, free from sulphur, and capable of being dried at atmospheric pressure without decomposition, are prepared by heating a nitrated aromatic phenol (dinitrophenol) with an equivalent quantity of an aqueous alkaline sulphide under a pressure equal to or greater than that of the atmosphere until complete reduction of the nitro groups is effected.—L. A. C.

Soluble dye in sheet form. F. Fear, Brooklyn, N.Y. U.S. Pat. 1,279,679, 24.9.18. Appl., 15.2.18.

A FIBROUS web is produced by beating unbleached paper stock composed of cotton fibres in a solution of sulphuric acid. The web is dried, led through a dye-bath, and again dried so as to crystallise the dyestuff upon the surface of the web.—L. A. C.

Anthracene derivative [pyranthridone]; Production of an —. R. Scholl, Dresden. Ger. Pat. 307,399, 11.11.16.

A NEW compound, pyranthridone (this J., 1918, 364 A), applicable in the dye industry, is prepared by the action of dehydrating agents on 5-methyl-3,4-phthaloyl-8-(CO)-9-benzoylenephenaanthridine.

—J. H. L.

Anthracene dyes and process of making same. R. Bohn, Mannheim, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,280,648, 8.10.18. Appl., 8.5.15.

SEE Eng. Pat. 160,580 and 160,581 of 1915; this J., 1916, 831.

Azo dye and process of making. E. F. and H. W. Ehrhardt, Birmingham. U.S. Pat. 1,281,243, 8.10.18. Appl., 4.1.18.

SEE Eng. Pat. 113,181 of 1917; this J., 1918, 202 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

PATENTS.

Viscose; Manufacture of threads from —. T. H. Verhave, The Hague, Netherlands. U.S. Pat. 1,280,338, 1.10.18. Appl., 23.2.15.

SEE Eng. Pat. 2485 of 1915; this J., 1916, 250. It is specified that the spinning bath should contain at least "3 mols. SO₄ ions to each 2 mols. H-ions."

Composition or pulp [for paper-making]. U. Okazaki, Kitaguchi, Assignor to H. E. Ridings, Yokohama, Japan. U.S. Pat. 1,278,199, 10.9.18. Appl., 1.11.17.

A FIBROUS composition or paper-making pulp is prepared by treating sugar-cane leaves with water, caustic soda, lime, bleaching powder, and sulphuric acid.—J. F. B.

Paper; Means for imparting surface finish to —. H. P. Howe, Steep Falls, Assignor to Eastern Manufacturing Co., South Brewer, Me. U.S. Pat. 1,278,659, 10.9.18. Appl., 2.2.18.

The machine comprises a pair of curved finishing plates covered with linen fabric which is maintained under tension on the convex surface of each plate. The curved plates are oscillated in tangential contact with each other between a pair of calender rolls. Means are provided for feeding sheets of paper between the two oscillating plates and for stacking them in a receiving box after passing between the rolls. A jet of air is directed under the finished sheets to lift them from the finishing plates for delivery to the stack. Feeding and receiving arrangements are provided on both sides of the machine so that the plates are utilised in both strokes of their oscillation.—J. F. B.

Paper; Method and machine for making —. C. E. Pope, Springfield, Mass., Assignor to Great Northern Paper Co., Millinocket, Me. U.S. Pat. 1,279,756, 24.9.18. Appl., 14.3.18.

To remove the paper web from the papermaking wire at the beginning of the operation of the machine or after a break, a narrow strip of the paper is formed at one edge of the wire and two oppositely directed transverse jets of air are directed against the two edges of the strip at the point where the strip leaves the wire, so as to meet behind the strip. The adhesion of the strip of paper to the wire is thus broken at this point, and the strip deflected from the roller so as to fall on to the press roll felf.—W. F. F.

Paper; Manufacture of acid- and weatherproof —. Hedderheimer Kupferwerk und Süddeutsche Kabelwerke A.-G., Abt. Süddeutsche Kabelwerke in Mannheim. Ger. Pat. 307,867, 5.1.18.

AN oxidising agent such as red lead or the like is incorporated with the paper pulp and the dry finished paper is subsequently impregnated with a drying oil, which is oxidised in the paper to a coherent protective layer capable of resisting acids and moisture.—J. F. B.

Sulphite-cellulose waste lyes; Purification of — by treatment with flue gases. H. Achenbach, Nussdorf. Ger. Pat. 306,898, 17.6.15.

THE spent liquor from the digester, which may undergo a preliminary purification by spraying, is fed into the top of a scrubbing tower packed with stones and allowed to trickle down in contact with ascending hot flue gases. The concentrated liquor is collected at the bottom of the tower, whilst the vapours containing sulphur dioxide and volatile acids pass away through the hood of the tower, together with the exhaust gases, into a horizontal tubular cooler containing arrangements which facilitate the maximum utilisation of the cooling water. The condensed water containing sulphur dioxide in solution collects in the lower part of the cooler and is drawn off to a reservoir for the production of fresh liquor. The gases, also containing some sulphur dioxide, pass through a pipe to an absorption tower.—J. F. B.

Sulphite-cellulose waste lyes; Recovery of useful organic and inorganic substances from — by heating in autoclaves. R. W. Strehlenert, Göteborg, Sweden. Ger. Pat. 308,144, 1.4.17.

THE waste lye is treated in an autoclave with gases or vapours of an acid character, for instance, the exhaust gases from the sulphite pulp digesters con-

taining sulphur dioxide. The gas is forced into the autoclave at a pressure which is substantially higher than that corresponding to the temperature of the liquor therein, for instance, with the liquor heated at 190° C. the gas pressure may amount to 20 atm. The liquor may be heated in a series of interconnected pressure vessels fed with gas from the autoclave in front of them. An oxidising gas, such as air, may be mixed with the acid gases employed for the reaction. The sulphur dioxide in the liquor is converted by the treatment, according to the equation $3\text{SO}_2 = 2\text{SO}_3 + \text{S}$, into sulphuric acid, which causes the precipitation of the organic matter.—J. F. B.

Paper twine or yarn; Manufacture of — A. D. Spicer, and J. Spicer and Sons, Ltd., London. Eng. Pat. 120,236, 19.10.17. (Appl. 15,207/17.)

Cellulose acetate and process of making same. Process of making cellulose acetate insoluble in chloroform and in chloroform-alcohol. II. Dreyfus, Basle, Switzerland. U.S. Pats. 1,280,974 and 1,280,975, 8.10.18. Appls., 4.5.15 and 15.6.16.

SEE FR. Pat. 475,160 of 1914; this J., 1916, 40.

Drying yarns, jute, etc. Eng. Pat. 120,277. See XV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENT.

Fabric dyeing processes [using organic solvents]. W. P. Thompson, Liverpool. From V. Planté, Marseilles, France. Eng. Pat. 119,881, 17.8.17. (Appl. 11,825/17.)

Wool, silk, etc., are dyed with basic dyestuffs dissolved in carbon tetrachloride, to which alcohol may be added, in the presence of a mordant termed "gallo-oleate of ammonia." The mordant is prepared by mixing 55 parts of triolein, 5.5 of alcohol, 1 of gallic acid, and 13 of 22% ammonia solution, and stirring until saponification is complete. The dye-bath, suitable for dyeing 66 lb. of material, is composed of: carbon tetrachloride, 25.5 galls.; alcohol, 17 galls.; mordant, 41 lb.; basic dyestuff, 22 lb. The mixture is heated to 145° F. (62.5° C.) and dyeing is carried out in an iron vessel with occasional agitation for 3–4 hours. During the operation an electric current, preferably of 250 amps. at 450 volts, is passed through the bath. The dyed material is drained in a hydro-extractor, dried, and treated in a vat containing a solution of 6.5 lb. of "gallo-oleate of ammonia" in 33 galls. of petroleum spirit, and finally rinsed in fresh petroleum spirit. —J. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitre cake; Summary of the literature on the solubility of systems relating to — H. W. Foote. J. Ind. Eng. Chem., 1918, 10, 896–897.

ARÉSUMÉ of the literature dealing with the solubility relationships of the systems, $\text{Na}_2\text{SO}_4\text{—H}_2\text{SO}_4\text{—H}_2\text{O}$, $\text{Na}_2\text{SO}_4\text{—RSO}_4\text{—H}_2\text{O}$, and $\text{RSO}_4\text{—H}_2\text{SO}_4\text{—H}_2\text{O}$.—J. F. S.

Nitre cake; Recrystallisation of — B. Saxton. J. Ind. Eng. Chem., 1918, 10, 897–901.

Using the solubility data of D'Ans and Pascal (this J., 1906, 534; 1917, 594) equations have been developed for the efficient working of the following processes: (1) separation of any one solid phase of the system $\text{Na}_2\text{SO}_4\text{—H}_2\text{SO}_4\text{—H}_2\text{O}$, (2) separation of a stated amount of one solid phase of the same system, (3) separation of the maximum amount of each solid phase. These equations are for the temperatures 0° C. and 25° C. Leaching processes are outlined, by means of which sulphuric acid may be concentrated in the solution and sodium sulphate in the solid. It is found experimentally that this separation can be carried out more efficiently at 0° than at 25° C.—J. F. S.

Kaolin rich in iron; Utilisation of — [for manufacture of alum or aluminium sulphate]. J. Milbauer and F. Skutil. Chem.-Zeit., 1918, 42, 525–527.

For the manufacture of alum or aluminium sulphate from kaolin containing a large proportion of iron, the best method consists in heating the mineral at 700° C. with the addition of sawdust; air must be excluded during the heating. The calcined material is then heated with sulphuric acid (50° B., sp. gr. 1.53); the ferrous sulphate remains in solution when the aluminium sulphate is separated by crystallisation. Traces of ferric salts may be removed from the aluminium sulphate solution by adding potassium ferrocyanide and filtering, a small quantity of Kieselguhr being added to facilitate the filtration. If, after the iron salts have been reduced, the aluminium sulphate is allowed to crystallise in an atmosphere free from oxygen, the crystals obtained contain but very little iron.—W. P. S.

Carbon monoxide; Oxidation of — in contact with copper. K. A. Hofmann. Ber., 1918, 51, 1334–1346.

In contact with metallic copper moistened with aqueous potassium hydroxide, carbon monoxide mixed with air is oxidised two or three times more rapidly than it is when in contact with a copper oxide surface of the same area. The copper is converted into a peroxide, Cu_2O_2 or CuO_2 , which is the active oxidising agent. The rate of oxidation is increased when the copper surface is coated with a trace of iridium. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Carbon monoxide; Activation of — by metallic copper, the producer gas-cell, and the electro-motive activation of alkali formates. K. A. Hofmann. Ber., 1918, 51, 1526–1537.

The author's discovery (see preceding abstract) that carbon monoxide can be rapidly oxidised at the ordinary temperature has enabled him to realise the producer gas-cell $\text{O}_2 | \text{Cu} | \text{alkali} | \text{Cu} | \text{CO}$, and the drawbacks of most of such cells have been overcome (subject of a censored patent). The E.M.F. ($\text{CO} \rightarrow \text{CO}_2$) is found to be 1.32 volts at 20° C., which compares well with the value 1.343 at 17° C. calculated by Nernst and von Wartenberg from the dissociation of carbon dioxide. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Hydrogen; Detection and determination of hydrogen phosphide in — J. Soyer. Ann. Chim. Analyt., 1918, 23, 221–225.

HYDROGEN prepared for aeronautical purposes by the action of sodium hydroxide on ferrosilicon always contains traces of hydrogen phosphide (from 1 in 15,000 to 1 in 40,000 vols., or less). The presence of

the hydrogen phosphide may be detected by the green coloration of the flame when the gas is burnt from a platinum jet, by the spectrum (phosphorus lines) exhibited by the flame, and by the detection of phosphoric acid when a drop of water is held in the flame for 15 secs. and then tested with molybdic acid reagent. To determine the hydrogen phosphide, from 2 to 20 litres of the hydrogen is conducted together with a large excess of air to a platinum jet fitted in a silica tube heated to bright redness. This tube is inclined slightly, and the lower end is cooled and connected with a series of absorption vessels containing water. The combustion of 20 litres of the gas takes about 1 hr. At the end of the operation, the contents of the absorption vessels are transferred to a basin, the silica tube is also rinsed out with water, and, after the addition of 5 grms. of ammonium nitrate, the solution is concentrated to about 40 c.c., and the phosphoric acid precipitated in the usual way with molybdic acid reagent. If the yellow precipitate obtained is very small, its quantity may be determined colorimetrically.—W. P. S.

Gas purification. Parrish. See IIA.

• *Lime-alumina-silica.* Neumann. See X.

Colloidal silicic acid. Mary. See XVII.

PATENTS.

Sulphuric acid [and zinc]; Manufacture of —. J. F. Cullen, Midvale, Utah, Assignor to United States Smelting, Refining, and Mining Co. U.S. Pat. 1,278,308, 10.9.18. Appl., 13.9.17.

In a cyclic process, zinc ore is dissolved in sulphuric acid, manganese dioxide (ore) is added to the solution, and the mixture is treated with sulphur dioxide to produce a solution of zinc and manganese sulphates. The latter is then electrolysed, an insoluble anode being employed, under conditions whereby zinc is deposited at the cathode while sulphuric acid and manganese dioxide are produced at the anode.—W. E. F. P.

Evaporating furnaces for surface heating, particularly for the concentration of acids. Chem. Fab. zu Schöningen, and R. Vetterlein. Ger. Pat. 307,564, 27.8.16.

THE liquid to be evaporated and the heating gases are passed in contact in opposite directions and in a horizontal zig-zag path through the evaporator, consisting of a metal pan built in a masonry setting, and through a preliminary evaporator consisting of a reaction tower built above one end of the metal pan. The liquid is sprayed into the top of the tower, which may be filled with packing, and meets the ascending exhaust gases from the main evaporator; it is collected in the pan beneath and flows in contact with the furnace gases through the pan, which is divided by partitions into zig-zag channels, to the outlet near the furnace. The pan may be constructed of wrought iron, and supported on pillars in the masonry setting. In the evaporating space all baffling obstructions are avoided, and doors are fitted in the walls at the ends of the channels to facilitate cleaning of the trough.—J. F. B.

Aluminous compounds [from clay, etc.]; Production of —. W. B. Llewellyn, H. Spence, and P. Spence and Sons, Ltd., Manchester. Eng. Pat. 119,924. (Appls. 15,711, 29.10.17 and 3152, 22.2.18.) Addition to 112,881, 11.5.17 (this J., 1918, 149 A).

A hot or boiling solution of sulphuric acid, or of aluminium sulphate containing free sulphuric acid,

is circulated repeatedly through a mass composed of small lumps of clay, fireclay, lithomarge, or similar material, preferably ignited previously, until the alumina is completely extracted from the material, and a concentrated, acid or basic solution of aluminium sulphate is obtained for use as such or for conversion into other compounds of aluminium. The process is more particularly applicable to clays, etc., possessing, naturally or as the result of ignition, a structure permitting of ready circulation of liquid through the mass. Aluminous minerals containing much potash are unsuitable.—W. E. F. P.

Ammonium chloride from ammoniacal liquor; Recovery of —, with the extraction of cyanides and other valuable products. H. Baker, Barrow-in-Furness. Eng. Pat. 119,971, 22.1.18. (Appl. 1211/18.) Addition to 112,329, 17.1.17 (this J., 1918, 88 A).

AFTER the removal of free ammonia by boiling, the liquor is concentrated or evaporated to dryness before recovering the cyanides and ammonium chloride by the original process. The waste gases from the ammonia-recovery plant are employed to precipitate any metals remaining in solution after recovering the cyanides.—W. E. F. P.

Caustic soda and the like; Machine or apparatus for breaking up or pulverising —. W. Blacker, Stalybridge. Eng. Pat. 120,309, 21.1.18. (Appl. 1154/18.)

IN an apparatus for breaking up caustic soda, etc., which has been allowed to set in drums or other containers, the container is struck repeatedly, and in different places, by a power hammer having one or more striking heads, whilst supported upon and moved by a mechanical cradle actuated by the hammer device.—W. E. F. P.

Cream of tartar from wine- lees. H. Tobler, Haeckensack, N.J. U.S. Pat. 1,278,257, 10.9.18. Appl., 9.11.17.

A MIXTURE of wine- lees and sulphuric acid of strength 10° B. (sp. gr. 1.074) is heated to about 60° C., with agitation, and filtered, and the solution is treated with potassium compounds and alkali to produce cream of tartar. The mother liquor, from which the latter is separated, is treated with a calcium salt to precipitate calcium tartrate which is added to a subsequent charge of wine- lees.

—W. E. F. P.

Cyanogen compounds; Production of —. J. D. Morgan, New York. U.S. Pat. 1,278,493, 10.9.18. Appl., 30.6.17.

AN intimate mixture of an alkali-metal compound and carbonaceous matter is showered into a heated reaction chamber in which an atmosphere consisting largely of nitrogen is maintained. The cyanogen compound formed adheres to the walls of the chamber, and is removed periodically while in a plastic condition.—W. E. F. P.

Barium chloride, magnesium chloride, etc.; Process for the production of —. S. H. Dolbear and J. W. Beckman, San Francisco, Cal. U.S. Pat. 1,279,090, 17.9.18. Appl., 5.10.15.

A BARIUM compound is mixed with sodium chloride, heated to 1500°–2500° F. (815°–1370° C.), and treated with water, whereby the sodium chloride dissolves and the barium compound remains in a finely divided condition. The mixture is evaporated to dryness, mixed with silica, and again heated to the above temperature.—W. F. F.

Alum; Process of making —. E. W. Haslup, Bronxville, N.Y., and B. A. Peacock, Philadelphia, Pa. U.S. Pat. 1,279,109, 17.9.18. Appl., 7.11.17.

AN alkali-metal alum is made from a mixture of a mineral containing alkali metal compounds (e.g., "green sand") and bauxite by digesting with sulphuric acid in a closed heat-insulated vessel.
—C. A. K.

Potassium sulphate; Process of obtaining —. B. A. Peacock, Philadelphia, Pa., Assignor to Haslup and Peacock, Inc., New York. U.S. Pat. 1,279,145, 17.9.18. Appl., 8.2.18.

POTASSIUM in the form of sulphate is extracted from a hydrous mineral, such as glauconite, by mixing it with aluminium sulphate, the latter being present in a quantity only slightly in excess of that required to supply sufficient sulphuric acid to combine with the potassium present. The mixture is heated to a temperature above 100° C. to form potassium sulphate, which is then extracted by means of water.—B. N.

Cerium-group metals; Process of obtaining compounds of — from monazite sands. W. S. Chase, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,279,257, 17.9.18. Appl., 20.11.16.

COMPOUNDS of metals of the cerium group are obtained by decomposing monazite sands by sulphuric acid, and then adding sodium bisulphate to precipitate double sulphates of sodium and these metals.—B. N.

Perhalates [sodium perchlorate]; Process of producing —. E. P. Schoch and R. H. Pritchett, Austin, Tex. U.S. Pat. 1,279,593, 24.9.18. Appl., 18.4.18.

SODIUM perchlorate is produced by electrolysis of an acid solution of sodium chlorate, an anode of gas retort carbon being employed.—W. E. F. P.

Catalytic substances; Manufacture of active —. F. Müller, Freiburg. Ger. Pat. 307,380. 26.3.16.

COMPLEX salts of the heavy metals, known as "Werner salts," are heated in absence of air at temperatures not exceeding those at which the catalytic reaction is to be carried out. The salts may be heated either in their original form or distributed on carrier masses in a current of nitrogen, or in an atmosphere of one or more of the gases with which the catalytic agent is to be used. Alternatively, the "Werner salts" may be finely divided and heated in the presence of liquids, except in the case of the complex salts of the platinum metals intended for use as catalysts in the process of fat hardening. The "Werner salts" comprise double salts and complex salts, such as potassium chromeyanide, ammonium ferrimolybdate, nitro-purpureonate, sodium-ammonium cobaltcyanide, and carbonato-pentammine cobalt nitrate for ammonia synthesis, cerocobalt nitrate for the production of formaldehyde from methane and oxygen, hexaquo-chromium acetate for the production of indole from methyl-*o*-toluidine and hydrogen, hexaquo-chromium propionate for production of camphor from a solution of borneol in paraffin oil, luteo-chromium ferrieyanide for oxidation of ammonia, and cobalt hydroxynitrite for production of sulphur trioxide from sulphur dioxide and excess of oxygen.—J. F. B.

Chalk; Light precipitated — and processes of making same. N. Statham, Hastings-on-Hudson, N.Y., U.S.A. Eng. Pat. 120,219, 26.7.17. (Appl. 10,780/17.)

SEE U.S. Pat. 1,266,339 of 1918; this J., 1918, 415 A.

Tungsten and nitrogen; Producing compounds containing —. C. Bosch and A. Mittasch, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,278,580, 10.9.18. Appl., 11.11.12.

Manganese sulphate. U.S. Pat. 1,279,110. See X.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass-furnace. C. R. Hook, Coffeyville, Kans. U.S. Pat. 1,279,697, 24.9.18. Appl., 5.7.17.

THE two hot-air flues leading from the regenerators at opposite sides of a glass furnace communicate with an air-passage, having an outwardly flared end, connected to the chimney. A vertical "butterfly" damper is arranged so as to connect either of the two hot-air flues with the chimney and the other one with the air-passage.—A. B. S.

Glass manufacture. R. H. Bolln, Rochester, N.Y. U.S. Pat. 1,280,139, 1.10.18. Appl., 17.2.15.

GLASS is allowed to flow from a stationary tank furnace into a movable receptacle surrounded by an air-chamber through which the glass is drawn in a continuous sheet by a pair of revolving bodies, one on each side of the chamber, which press on the edges of the sheet. The latter is supported on a column of air under pressure moving in the same direction as the glass. The tension on the glass is varied by altering the level of the glass in the receptacle.—A. B. S.

Separators; Centrifugal — [for treating clay "slip"]. R. S. Brownlow, Manchester. Eng. Pat. 120,319. (Appls. 2564, 13.2.18, and 10,231, 21.6.18.)

A CYLINDRICAL rotating vessel with its axis vertical is provided with a removable lining flanged externally at the top so as to rest on the rim of the vessel and rotate with it. The solid constituent of the mixture treated is deposited on the lining, which may then be raised out of engagement with the vessel by means of a framework of vertical rods co-operating with the flange of the lining, so that the solids may be removed. A complete withdrawal of the lining may be avoided by providing a piston at the bottom of the vessel, which may be raised by a vertical rod, thus carrying the solids with it. The solids may be consolidated before removal by providing the lining with a removable internal flange at the top, against which the solids may be compressed by the piston. In another modification two or more lifting pistons of different diameters may be provided to withdraw the solids in portions of different densities, and in a further modification

pistons may be provided at different depths to separate the solids according to their axial grading. The apparatus is particularly applicable for treating clay "slip."—W. F. F.

Continuous kiln for burning bricks, terra-cotta and the like. E. Glossop and J. Sherlock, Ambergate. Eng. Pat. 120,052, 23.10.17. (Appl. 5764/17.)

A CONTINUOUS chamber kiln of the transverse arch type is provided with a longitudinal hot-air flue, the bottom of which is connected by a series of small damper-controlled flues with the several chambers of the kiln, and the top of it by a series of overhead flues and down-cast flues to openings in the walls of the chambers, and to the flue which runs longitudinally in the sole of the kiln. In order to dry freshly-set goods, a current of air is drawn from a chamber containing cooling goods, through an opening near the top of the longitudinal hot-air flue, and is discharged into the chamber containing the freshly-set goods, through an opening connected to the bottom of the hot-air flue. As this warm air becomes saturated with steam and moisture, it is drawn off through flues in the partition walls and through an opening near the floor of the chamber into the main flue, and thence to the chimney. By withdrawing the moisture at positions equally distributed across the kiln, scum is prevented and the faces of the goods are kept clean.—A. B. S.

Tunnel-kilns; Method of and means for balancing draught in —. J. B. Owens, Metuchen, N.J. U.S. Pat. 1,278,991, 17.9.18. Appl., 16.11.17.

The ware is conveyed through the kiln by means situated below a horizontal platform extending across the kiln and engaging in longitudinal grooves at the sides, so that the kiln is divided into two separate compartments. The upper compartment containing the ware to be burned is strongly heated, and cooling air is admitted in regulated amount to the lower compartment to protect the conveying means. The air leaks slowly into the upper compartment through the spaces between the platform and the walls.—W. F. F.

Carbon blocks; Manufacture of —. T. W. S. Hutchins, Middlewich. Eng. Pat. 120,255, 31.10.17. (Appl. 15,885/17.)

CARBON blocks are made by compressing the finely ground material in hydraulic or other presses, the cylinder of the latter being coated with a film of graphite or a mixture of graphite with oil or grease, applied either before or during the charging of the cylinder with carbon, so that the binding of the charge during compression will be minimised and the whole body be carried forward by the plunger of the press and form a uniform non-porous mass. This is accomplished by fitting a tubular liner to the cylinder, applying the lubricant to the outside of the liner, whilst the charge is fed through the centre of it. The lower part of the liner may be made larger than the upper, and may be provided with hinged tongues.—A. B. S.

Abrasive. F. M. Becket, Assignor to Electro Metallurgical Co., Niagara Falls, N.Y. U.S. Pat. 1,279,828, 24.9.18. Appl., 10.4.16.

CLAIM is made for an abrasive composed of irregularly shaped grains, of approximately uniform size, of the alloy described in U.S. Pat. 1,245,552 of 1917 (this J., 1918, 13a), and for abrasive wheels, etc., containing bonded grains of the alloy.

IX.—BUILDING MATERIALS.

Wood paving blocks; Increasing the resistance of —. W. Ritter. *Bitmnen*, 1917, 15, 148—150. *Z. angew. Chem.*, 1918, 31, Ref., 308.

WOOD paving blocks in busy streets require renewal every 5—6 years, and attempts have been made to increase their strength by suitable impregnation. Tests were made of crushing resistance calculated per sq. cm. on prismatic blocks 75-75 sq. mm. in base area and 120 mm. in height, the pressure being applied in the direction of the fibres. Experiments in which sodium or potassium carbonate and sodium silicate in various proportions were added to an impregnating bath of pine wood tar showed no advantage, but increasing the temperature of the bath with the dry samples gave a 12% increase in strength. Experiments were also made by substituting heavy coal tar oil for the wood tar at temperatures from 112° to 140° C. At the higher temperature these trials gave as good results as those with wood tar, but the blocks impregnated at the lower temperature showed a crushing resistance inferior to that of the untreated blocks. Sodium carbonate alone, or still better sodium silicate alone, gave more favourable test results than the mixture of carbonate and silicate. The chemical composition of the impregnating bath, however, is of less importance than its temperature. The temperature should not be carried above 200° C. on account of the danger of splitting the blocks. The best strengthening results are obtained by impregnating for 3 hours with gradual increase of temperature up to 200° C. A test block showed a crushing strain of 323 kilos. per sq. cm. In the untreated condition; this was increased by impregnation at 100° C. to 330 kilos., at 120° C. to 345, at 140° to 487, at 150° to 516, and at 200° to 536 kilos.—J. F. B.

Lime-alumina-silica. Neumann. See X.

PATENTS.

Insulating material for cold storage. L. G. Surie, and Suristone, Ltd., London. Eng. Pat. 119,783, 17.1.18. (Appl. 992/18.)

GRANULATED cork, cork dust, sawdust, or the like, 2 lb., silica wool, 0.25 lb., casein, 1 lb., lime, 0.5 lb., and water, 5 lb., are mixed and moulded into slabs, which are hardened in a bath of formaldehyde, and dried. The dried slabs are treated with calcium tannate solution to render them damp-proof. —W. F. F.

Heat-insulating material and method for manufacturing same. P. A. Boeck, New York, and W. L. Jordan, Glendale, Cal. U.S. Pat. 1,279,975, 24.9.18. Appl., 12.3.18.

A HEAT-INSULATING material is produced by forming a suspension of hydrated basic magnesium carbonate in water, adding an alkali hydroxide, heating the mixture, and then adding diatomaceous earth and fibrous material. Part of the magnesium reacts with the silica in the diatomaceous earth, forming magnesium silicate.—A. B. S.

Cement; Acid-resisting —. Chance and Hunt, Ltd., A. E. Holley, and H. W. Webb, Oldbury. Eng. Pat. 119,966, 12.1.18. (Appl. 749/18.)

ACID-RESISTING cement, consisting of an acid-resisting silicious material and an aqueous solution of sodium silicate, is made more quick-setting by adding about 1.5% of lead carbonate or basic lead carbonate.—W. F. F.

Gypsum; Process of burning — E. Fischer, Pilsen, Bohemia. Ger. Pat. 307,808, 1.1.18. Int. Conv., 15.11.15.

PLASTER of Paris of uniform character is produced from gypsum of varying density by burning the latter in pieces the size of which is in inverse ratio to their density.—J. H. L.

Cement; Processes of producing — and recovering potassium compounds. F. W. Huber and F. F. Reath, Riverside, Cal., U.S.A. Eng. Pat. 110,510, 27.8.17. (Appl. 12,289/17.) Int. Conv., 26.9.16.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cementite transformation; Study of — and of the equilibrium diagram of the iron-carbon system by means of electric resistance measurement. I. Iitaka. Sci. Rep. Tôhokô Imp. Univ., 1918, 7, 167—175.

By a highly sensitive arrangement of apparatus the author was able to detect the cementite conversion in steel by means of the change in electrical resistance, and also to plot a line where, during cooling, cementite begins to separate from austenite, or during heating, the dissolution of free cementite in ferrite terminates (the so-called SE line). The test specimen, in the form of a cylindrical rod 20 cm. long and 5 mm. diam., enclosed in an evacuated silica tube, formed part of a circuit carrying a constant current of 5 amperes, and a differential galvanometer, connected through two resistances, indicated any difference of potential between two points on the rod 8 cm. apart. The silica tube was heated in a resistance furnace, and the resistances in circuit with the galvanometer were so adjusted that a zero reading was obtained when a current of 5 amperes was passing through the specimen. As the temperature was raised, the deflection of the galvanometer gradually increased with a rapid alteration at the transition point. The mean values for the A_0 point obtained with steels containing 0.31 to 1.50% C were 205° C. (Ac_0) and 197° C. (Ar_0), which are a little lower than when determined magnetically (215° C.). In a similar manner abnormal changes in resistance were observed during the A_1 , A_2 , and A_3 transformations, and a curve, ascending rapidly from the eutectoid point, with a curvature of downward concavity, was obtained as the solubility line (SE) of cementite in ferrite.—C. A. K.

Gold bullion; Refining — with chlorine gas and air. R. R. Kahan. Bull. 170, Inst. Min. Met., Nov., 1918. [Advance copy.] 4 pages.

In the chlorine process of refining, the greater part of the gold loss occurs in the final stages, and, as metal containing lead is too brittle for coinage purposes, the thorough chlorine treatment necessary for the complete removal of the lead causes a large loss of gold. It is desirable that the last of the base metals be removed while there is still considerable silver in the bullion. The following method, besides being shorter, resulted in a distinct reduction of the gold loss. Two clay pipe stems were introduced into the molten metal, for the delivery of air and chlorine respectively. At the beginning of the operation a maximum amount of air and a very slow stream of chlorine were used. The volume of air

was then diminished and that of the chlorine increased; finally the air pipe was removed. It was found an advantage in this process to mix brittle bullion with the most silvery metal available.

—W. R. S.

Alloys high in zinc. L. Guillet and V. Bernard. Rev. Mét., 1918, 15, 407—425.

The properties of alloys of zinc containing up to 8% Al and 8% Cu have been examined by mechanical and microscopical methods. The cast alloys do not present any interesting features in the mechanical tests; a breaking strain of 17 kilos. is attained when 8% Cu is present. A rolled bar containing 3% Al has a breaking strain of 23 kilos., with an extension of 15%, and corresponding figures for an alloy containing 2% Al and 3.6% Cu are 32 kilos. and 5%. When drawn down the alloys generally show a higher breaking strain and a greatly increased elongation. An alloy possessing somewhat similar mechanical properties to brass had the composition Zn (Pb 1%) 97.5 to 98%, Cu 1.5 to 2.0%. The elasticity, however, was much less than that of brass. The micrographic structure of zinc-aluminium alloys shows that two solid solutions are formed, one containing 0—4% Al, and the second 50—100% Al. These form a eutectic containing 5% Al (Shepherd, this J., 1905, 972), though it has been observed in an alloy containing only 1% Al, evidently due to heterogeneity of the metal. In the zinc-copper series there is a solid solution ' η ,' with 2.5% Cu, and where the copper present is between 2.5% and 13% a further solid solution ' ϵ ' forms, increasing with increase in the copper content. The latter solid solution gives rise to brittleness, and its formation should be restricted. A complete examination of the zinc-aluminium-copper system has not been made, but it appears that the solid solutions of zinc with aluminium, and of zinc with copper, are formed independently, and that the properties of the alloys correspond with the separate properties of these solutions. Macrographic examination shows large elongated crystals in the cast alloys, but the crystal structure is not so apparent in rolled or drawn metal. Heterogeneity is generally revealed, and is not influenced by annealing. The hardness of the alloys diminishes with increasing temperature, and the best temperatures for forging or working is given as 125° C. to 130° C.—C. A. K.

Metals; Occlusion of gases in — A. W. Porter. Faraday Soc., Nov. 12, 1918. [Advance proof.] 6 pages.

A REVIEW of the available data on the occlusion of gases in metals. The term "occlusion" is used to cover a number of different phenomena, which may be classified under the following heads: (1) Chemical combination of gas with metal, *e.g.*, hydrogen with sodium, potassium, or palladium; (2) solid solution in conjunction with chemical combination, as in the occlusion of hydrogen by lithium; (3) solid solution, *e.g.*, hydrogen in palladium; (4) solution accompanied by surface adsorption; (5) surface condensation under molecular forces, unaccompanied by solution; (6) inclusion, as when bubbles become entangled in the molten viscous metal. The term adsorption should probably be restricted to cases in which true solution takes place, but in which there is a modification of the concentration in the surface film, due to the influence of the dissolved body upon the surface tension. This phenomenon is quite distinct from surface condensation without solution. The Volta effect has often been attributed to condensed gases on the surface of the metals, but Langmuir (Trans. Amer. Electrochem. Soc., 1916, 29, 129) has shown that contact potentials of large magnitude exist between pure metals, even in a practically perfect vacuum.

Metals; Properties of — as affected by their occluded gases. C. Johns. Faraday Soc., Nov. 12, 1918. [Advance proof.] 4 pages.

REFERENCE is made to the widely differing phenomena which have been included under the term "occlusion of gases in metals," and it is pointed out that the properties of metals used for constructional purposes may be affected by their gaseous constituents more profoundly than is generally admitted. All the more complete investigations of metals used for industrial purposes have been made on specimens containing gaseous constituents, and there is no knowledge of the properties which the pure metals or alloys would possess if they could be produced.

Scrap metals and dross, etc.; Analysis [sampling] of —. Analysis of cement copper. O Binder. Chem.-Zeit., 1918, 42, 546.

SPECIMENS of scrap metals or dross, etc., usually contain large pieces of metal more or less coated with oxide, and it is impossible to obtain a fair average sample for analysis; it is recommended that, after the finer portions of the sample have been separated by a sieve, the larger pieces should be melted together and then filed so as to obtain a portion for weighing. In the determination of chlorine in cement copper, solution of the sample in nitric acid brings about loss of chlorine, and the copper is not dissolved completely.—W. P. S.

Flotation; Development of galena — at the Central Mine, Broken Hill. R. J. Harvey. Bull. 170, Inst. Min. Met., Nov., 1918. [Advance copy.] 17 pages.

THE ore is crushed to $\frac{1}{2}$ -in. mesh and jigged. The tailings are ground to 40-mesh size, and classified into slimes and "roughs." The latter product is treated with a mixture of coal tar and eucalyptus oil (2 oz. per ton) in "lead cascades," consisting of a series of 9 boxes (36 in. long, 18 in. wide, 28 in. high) set one above the other. The pulp, in descending from one box to another, passes through three nozzles and draws in the required amount of air. Two units of 9 boxes are in use. The slimes from the re-grinding are thickened and floated together with the "roughs." The successful application of this flotation process has resulted in the discarding of 24 tables and 30 vanners, and an increase of 8% in the effective lead recovery, i.e., to 85.6%. The silver recovery increased from 49.2 to 64.4%.

—W. R. S.

Tin ores; Effect of heating, and heating and quenching Cornish — before crushing. A. Yates. Bull. 170, Inst. Min. Met., Nov., 1918. [Advance copy.] 3 pages.

THE investigation was made in order to ascertain whether heating, and heating and quenching the ores before crushing, assisted the operation of crushing, diminished the breaking up of coarse particles of cassiterite and the production of slime, and facilitated the liberation of cassiterite grains from the gangue. It was found that the ores after heat treatment were more easily crushed, and contained a smaller proportion of the very fine slime from which very little tin is recoverable; but an improved recovery of tin was not obtained except in one case.—W. R. S.

Lime-alumina-silica; The system — and its relation to blast-furnace slags and Portland cement. B. Neumann. Stahl u. Eisen, 1918, 38, 953–960.

THE author gives a brief review of the present state of knowledge in regard to the ternary system

$\text{CaO-Al}_2\text{O}_3\text{-SiO}_2$, and its relation to blast-furnace slags and Portland cement, based principally on the results of recent investigations at the Carnegie Institution, Washington (this J., 1911, 543; 1913, 139). Blast-furnace slags and Portland cements occupy only small regions in the triangular diagram representing the complete ternary system. Johnson's work on blast-furnace slags (Met. and Chem. Eng., 1916, 363) is referred to, and the differences obtaining in blast-furnaces using charcoal and coke respectively are pointed out. In furnaces heated by coke, the sulphur in the latter necessitates the use of more lime ($\text{CaO} : \text{SiO}_2 = 1.5 : 1$) as flux, and a corresponding rise of about 200°C . in the flowing temperature of the slags. Calcareous slags are of low viscosity compared with the viscous, tough silicious slags. The temperature at which calcareous slags flow freely is only slightly above their softening point; silicious slags require a difference in temperature of $200^\circ\text{--}300^\circ\text{C}$. (compare Fulton, this J., 1913, 89). If the silica content is increased to 37% ($\text{CaO} : \text{SiO}_2 = 1.35 : 1$) the slag flows readily at a lower temperature, but the metal is not desulphurised; if the silica is reduced below 32%, both the furnace temperature and the amount of slag must be increased. Thus increasing the proportion of lime beyond a certain limit does not further improve the desulphurisation, the increased basicity being more than counterbalanced by the greater "stiffness" of the slag. Portland cements of good quality are comprised within the lines in the triangular diagram representing $3\text{CaO}, \text{SiO}_2$, $3\text{CaO}, \text{Al}_2\text{O}_3$, and $2\text{CaO}, \text{SiO}_2$. Portland cement made from pure materials and burned at a sufficiently high temperature would consist solely of these three substances. In commercial cements, the natural impurities in the materials result in free lime or free $5\text{CaO}, 3\text{Al}_2\text{O}_3$ being present, together with small quantities of magnesia, iron oxide, etc. As no ternary compound is present in the area of the triangular diagram occupied by cements, the theory of Jänecke (this J., 1911, 1453) and others that Portland cements consist chiefly of alite ($3\text{CaO}, \text{Al}_2\text{O}_3, 2\text{SiO}_2$) and other ternary compounds is untenable. Rankin's work on Portland cement (this J., 1916, 842) is reviewed and the following summary of the compounds formed in the production of Portland cement is given:—

Cement	Composition of raw materials	%	Burning temp.	Constituents in finished cement
Chemically pure cement	CaO	63.4	1650° C.	$2\text{CaO}, \text{SiO}_2$
	Al_2O_3	8.0		$3\text{CaO}, \text{SiO}_2$
	SiO_2	23.6		$3\text{CaO}, \text{Al}_2\text{O}_3$
White cement	CaO	66.2	1525° C.	$2\text{CaO}, \text{SiO}_2$
	Al_2O_3	6.4		$3\text{CaO}, \text{SiO}_2$
	SiO_2	25.0		$3\text{CaO}, \text{Al}_2\text{O}_3$
	$\text{MgO}, \text{Fe}_2\text{O}_3, \text{Na}_2\text{O}, \text{K}_2\text{O}$	2.4		Trace CaO
Commercial (grey) cement	CaO	63.2	1425° C.	$2\text{CaO}, \text{SiO}_2$
	Al_2O_3	7.7		$3\text{CaO}, \text{SiO}_2$
	SiO_2	22.4		$3\text{CaO}, \text{Al}_2\text{O}_3$
	$\text{MgO}, \text{Fe}_2\text{O}_3, \text{Na}_2\text{O}, \text{K}_2\text{O}, \text{SiO}_2$	6.7		Trace $\text{CaO}, \text{CaO}, 3\text{Al}_2\text{O}_3$ and ferrite

If the clinker is insufficiently burned, there will be a deficiency of $3\text{CaO}, \text{SiO}_2$. The tricalcium silicate appears to be the most valuable constituent of the cement; the dicalcium silicate hardens too slowly and the aluminate too rapidly. As the temperature of formation of tricalcium silicate is about 1700°C ., it is desirable to find some flux by means of which it can be produced at a lower temperature; ordinarily, calcium aluminate appears to have this effect. Rankin has suggested that the substitution of iron oxide for part of the alumina may lead to important industrial developments, and the author suggests that an investigation of the properties of the iron Portland cements is also desirable.

—A. B. S.

Electric resistance; Variation of — during the fusion of metals. H. Tsutsumi. Sci. Rep. Tôhokô Imp. Univ., 1918, 7, 93—105.

THE electrical resistance of a column of metal contained in a silica tube of small diameter was measured, at various temperatures, by a potentiometer method, the metal being protected from oxidation. Mercury, tin, lead, zinc, aluminium, silver, and copper show a considerable increase in electrical resistance during fusion, the ratio of the specific resistances of the metals in the liquid and solid states at the melting point being approximately equal to 2. Bismuth and antimony show a contrary effect, and a similar ratio for these metals is roughly $\frac{1}{2}$, which is attributed to a transformation in the molecular state during fusion.—C. A. K.

Chromium; Passivity of —. A. H. W. Aten. Proc. K. Akad. Wetensch. Amsterdam, 1918, 21, 138—150.

A DISCUSSION of the reasons for the activation of passive chromium by cathodic polarisation.

—J. F. S.

Silver; Colloidal —. A. Pickles. Chem. News, 1918, 117, 358.

COLLOIDAL solutions of silver are produced by adding 60% solutions of formaldehyde to silver oxide in water at 35° C. The solutions are very stable, and vary in colour from pale lilac to rich ruby red. Acetaldehyde has no action on silver oxide. The colour is discharged slowly by solutions of salts and by nitric acid. Hydrogen peroxide is slowly decomposed by the solution.—J. F. S.

Electrodeposition of metals. François. See XXIII.

PATENTS.

Steel-making furnaces, or mixers and the like. Wellman, Seaver, and Head, Ltd., London, and F. G. Smith, Purley. Eng. Pat. 120,114, 12.11.17. (Appl. 16,585/17.)

IN order to connect or seal various parts of the plant, such as the furnace and regenerator ports, the trough of the seal surrounding the lower port is provided with an independent inner trough, which contains a liquid into which enters a projection surrounding the upper port. The inner ring may be raised or lowered by mechanical means, or by causing it to float, by means of an enclosed air space, on a liquid in the outer trough, from which the liquid may be run off or admitted as required. Suitable guides for the inner ring are provided.

Iron and steel; Method of preparing pickled — for painting. J. H. Gravell, New York. U.S. Pat. 1,279,101, 17.9.18. Appl., 30.4.18.

SUBSEQUENT to the customary pickling of the metal in sulphuric acid, rapid rusting is prevented by removing the surface metal by a solution of phosphoric acid containing calcium phosphate.—C. A. K.

Metals; Cleaning —. J. H. Gravell, New York. Eng. Pat. 119,618, 22.3.18. (Appl. 5113/18.)

SEE U.S. Pat. 1,279,101 of 1918; preceding. An alcoholic solution of phosphoric acid containing calcium phosphate is used.

Iron and steel; Pickling —. J. H. Gravell, New York. U.S. Pat. 1,279,331, 17.9.18. Appl., 11.5.18.

THE metal is subjected to the action of a mixture of sulphuric and phosphoric acids, then to the action of an aqueous solution of a blebromate.—T. H. B.

Iron alloy. H. K. Sandell, Assignor to H. S. Mills, Chicago, Ill. U.S. Pat. 1,279,148, 17.9.18. Appl., 18.6.17.

AN alloy of 45 parts by weight of Ni, 50 parts Cu, 100 parts Fe, and a relatively small proportion of Mn.—T. H. B.

[Iron] pipes; Heat treatment for centrifugally cast —. D. S. de Lavaud, New York. U.S. Pat. 1,280,418, 1.10.18. Appl., 30.7.17.

MOLTEN iron is fed into a rotary metal mould, and the mould rotated to compress the molten metal against its sides by centrifugal force, while congealing the metal within six seconds. The casting is withdrawn as quickly as possible, heated to at least 1800° F. (980° C.), and then allowed to cool. The graphite is very fine on the outside of the casting, increasing in coarseness towards the centre, and the outer portion is easily worked by any tool. The structure of the casting comprises dendrites and grains of silicoferrite and grains of ferrite containing fine graphite surrounded by a network of pearlite.—T. H. B.

Ores; Process and apparatus for treating — in the blast furnace. L. P. Basset, Paris. Eng. Pat. 109,452, 7.9.17. Int. Conv., 7.9.16.

THE carbon used as fuel is injected in the form of dust into the lower part of the blast furnace, air being admitted in such proportion as to generate carbon monoxide only, the fraction of the carbon escaping combustion acting as a reducing agent. Wrought iron, cast iron, or steel can be produced as desired by varying the proportions of air and carbon injected, and carbon in coarser form may be added to the ore in suitable proportion to effect a direct reducing action.—T. H. B.

Furnaces for annealing, hardening, or heat treatment of metals, and the like. A. Smallwood, London. Eng. Pat. 120,266, 5.11.17. (Appl. 16,159/17.)

A FURNACE has an elongated heating chamber, and in alignment with this is a charging chamber of similar size, which extends downwards into a wider chamber capable of being filled with water so as to seal the charging and heating chambers. A trolley car in this chamber, but outside the wall of the charging chamber, is loaded with material for heat treatment, and is moved laterally on rails beneath the charging chamber, and elevated into it above the water level. Charging mechanism then conveys the material from the trolley car longitudinally into the heating chamber.—C. A. K.

Billet-heating and like furnaces. A. Crowcroft and F. Morris, London. Eng. Pat. 120,348, 15.5.18. (Appl. 8137/18.)

IS a billet-heating furnace of the continuous type, heated by two fires on opposite sides of the furnace, the fire-holes are set not directly opposite one another, the gases of combustion thereby causing a circulatory motion over the centre of the hearth before their discharge through ports on either side of the combustion chambers. Air, or a mixture of air and steam, is blown through the fire-grates, and a secondary supply of preheated air is supplied above the fires.—C. A. K.

Metal-melting crucibles; Heating device for —. G. L. Fort, Assignor to Fort-ified Manufacturing Co., Kansas City, Mo. U.S. Pat. 1,279,682, 24.9.18. Appl., 18.7.17.

A CRUCIBLE provided with a delivery spout is in contact on its under side and along the delivery spout with an electrical heating unit. The whole is sur-

rounded by an insulated metal casing having an opening in the base, through which the heating element may be removed or inserted.—C. A. K.

Heating furnace. C. W. Lummis, Assignor to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,279,889, 24.9.18. Appl., 27.4.14.

A CONTINUOUS billet-heating furnace is divided into a number of narrow compartments by means of transverse partitions carried from the crown of the furnace, sufficient space being allowed above the hearth to enable the billets to be moved longitudinally along the furnace. Products of combustion travel parallel to the partitions.—C. A. K.

Antimonial and arsenical gold ores; Treatment of —. J. Penhale, Johannesburg, and W. H. Treloar, Langlaagte, Transvaal. Eng. Pat. 120,287, 3.12.17. (Appl. 17,884/17.)

GOLD ores containing antimony sulphide and/or arsenic sulphide are crushed and slimed in an aqueous solution of an alkali sulphide; after separation of the liquid, the remaining ore is ready for cyaniding, or other extraction process; the base metals may be recovered by acidifying the alkali sulphide solution.—T. H. B.

Copper ores; Process of treating — by lixiviation. N. C. Christensen, Salt Lake City, Utah, Assignor to J. E. Barlow, Habana, Cuba, and Big Indian Copper Co. U.S. Pat. 1,278,854, 17.9.18. Appl., 1.9.16.

COPPER ores are lixiviated with a concentrated solution of sulphur dioxide made by first bringing the solution in contact with gases relatively poor in sulphur dioxide and then successively in separate absorbers, with gases relatively stronger in sulphur dioxide. A lime compound may be added to the solution during the lixiviation in order that all of the copper may be recovered as copper sulphite.

—C. A. K.

Concentrating ores by flotation; Method and apparatus for —. C. C. Thomas, Baltimore, Md. U.S. Pat. 1,279,040, 17.9.18. Appl., 28.6.16.

ORE pulp is agitated by means of heated products of combustion, such as the exhaust gases from an internal combustion engine. The gases are discharged into the flotation cell through an atomising device.—C. A. K.

Drying mechanism for electro-plating apparatus. M. F. Davoran, Assignor to The Crane and Breed Manufacturing Co., Cincinnati, Ohio. U.S. Pat. 1,279,086, 17.9.18. Appl., 3.8.17.

A HORIZONTAL drying chamber is provided at one end with means for discharging a forced blast of air away from the chamber in a direction inclined to its axis. Air passes through the chamber towards the air blast, and is deflected at several points in the chamber into contact with heating devices. The articles to be dried are conveyed past the air blast and through the chamber.—W. F. F.

Manganese from lean ores; Process of extracting —. *Process of producing manganese sulphate.*

(A) E. W. Haslup, Bronxville, N.Y., and B. A. Peacock, Philadelphia, (B) E. W. Haslup, Assignor to Haslup and Peacock, Inc., New York. U.S. Pats. (A) 1,279,108 and (B) 1,279,110, 17.9.18. Appls., 7.11.17 and 2.2.18.

(A) A MIXTURE of the ore and a material capable of producing an exothermic reaction in the process, e.g., a potassium compound, is finely ground and

digested with sulphuric acid of not more than 55° B. (sp. gr. 1.616) in a closed heat-insulated vessel for not less than 15 hours. A temperature of 150° C. is attained by the heat of reaction and the sulphates formed are lixiviated with water and the metal values recovered. (B) Low-grade material containing manganese oxide is finely divided and digested in a solution of a metal sulphate capable of attacking the manganese oxide present. Ferrous sulphate or aluminium sulphate, derived for example from "greensand," may be employed at a reaction temperature of 60° C.—C. A. K.

Ores; Apparatus for reducing —. H. N. Tracy, Los Angeles, Cal. U.S. Pats. (A) 1,279,180 and (B) 1,279,181, 17.9.18. Appls., 11.1 and 1.3.17.

(A) THE ore is continuously heated in a tall and narrow vertical stack, and a gaseous reducing agent is continuously introduced near the middle of the column of material. The reduced ore is withdrawn at the bottom, and charging and withdrawal are so arranged as to keep the height of the column of ore constant. (B) The ore is continuously cooled at the bottom of the column, and means are provided for transferring heat from the cooling ore to fresh ore which is thus preheated prior to its introduction into the top of the stack.—T. H. B.

Zinc; Apparatus for treating —. C. A. H. de Saulles, New York. U.S. Pat. 1,279,202, 17.9.18. Appl., 10.7.17.

PROVISION is made for the transference of molten zinc from a melting furnace, in which separation of lead takes place by gravitation, to a distillation plant in the condensing part of which liquid zinc is produced. The molten zinc is discharged from the condensers into a mixing furnace, from which it may be returned to the distilling furnace.—C. A. K.

Metals; Case-hardening of —. P. W. Shimer, Easton, Pa. U.S. Pats. (A) 1,279,457 and (B) 1,279,458, 17.9.18. Appl., 3.1.18.

(A) THE metal is immersed in a bath of fused salts in which calcium cyanamide has previously been immersed until a vigorous evolution of gas has occurred and then removed. (B) A mixture of calcium cyanamide and hard pitch or other coking binder is coked, and the residual mass is broken up into fragments of suitable size for use in case-hardening.—T. H. B.

Electrolytic process [for impure copper solutions]. W. E. Greenawalt, Denver, Colo. U.S. Pat. 1,279,860, 24.9.18. Appl., 24.2.14. Renewed 26.2.18.

A PORTION of the copper solution, containing salts of iron, is separated from the electrodes, and a finely-divided sulphide reducing agent, e.g., hydrogen sulphide in an atomised form, is agitated in contact with the separated electrolyte. The iron salts are reduced to the ferrous condition, the insoluble matter filtered off, and the filtered electrolyte returned to the electrodes.—B. N.

Electroplating; Method of and apparatus for —. C. A. Hach, Oak Park, Ill., Assignor to Western Electric Co., Inc., New York. U.S. Pat. 1,280,213, 1.10.18. Appl., 12.1.17.

A CONSTANT stream of gas is delivered through an inert porous material, forming bubbles which remove the hydrogen bubbles generated on the article connected to the cathode during the plating operation.—B. N.

Plating; Method of and apparatus for [electro] —. G. A. Landry, Chicago, Ill., Assignor to Western Electric Co., Inc., New York. U.S. Pat. 1,280,249, 1.10.18. Appl. 15.1.17.

THE cathode is completely enclosed in a perforated cup-shaped anode, the interior contour of which is shaped to conform substantially to the shape of the cathode, and the latter is rotated so as to agitate the solution in the anode.—B. N.

Ores; Method of sintering —. E. J. Hellman, Perrysburg, Ohio. U.S. Pat. 1,280,221, 1.10.18. Appl. 3.1.18.

A LAYER of the ore is spread on a moving surface, the upper surface of the ore ignited, a second layer then spread over the first one, and its upper surface ignited, air being drawn downwards through both layers simultaneously to promote combustion.

—T. H. B.

Metal article; Corrosion-resisting — and method of making same. W. J. Merten, Pittsburgh, Pa., Assignor to G. D. Breck, Cleveland, Ohio. U.S. Pat. 1,280,268, 1.10.18. Appl. 4.1.18.

THE opposite sides of metal articles which are subjected to different corroding influences are treated simultaneously by different corrosion-inhibiting processes, which require for their performance the same elevated temperature. For example, in the case of iron tubes or the like, the opposite sides of which are subjected to heat and moisture respectively, as in steam generating apparatus, the side which is to be subjected to moisture is sherardised and the opposite side is simultaneously coated with magnetic oxide.—T. H. B.

Ores; Process of roasting —. A. B. Newman, Langeloth, Pa., Assignor to Metallurgical Co. of America, New York. U.S. Pat. 1,280,283, 1.10.18. Appl. 23.3.16.

IN roasting ores in a multiple hearth furnace, the roaster gases are enriched in sulphur dioxide, by burning sulphur in the lower levels of the furnace with insufficient air for complete combustion, and subsequently introducing further amounts of air to complete the combustion, whereby heat is supplied directly to the ore bed and the furnace gases are enriched in sulphur dioxide.—T. H. B.

Coating metal; Processes for —. B. P. Allen, Great Neck Station, N.Y., U.S.A. Eng. Pat. 113,602, 31.10.17. (Appl. 15,867/17.) Int. Conv. 19.2.17.

SEE U.S. Pat. 1,233,633 of 1917; this J., 1917, 1015.

Zinc; Furnace for treating —. L. Van Gulek, Swansea. U.S. Pat. 1,280,593, 1.10.18. Appl. 21.7.17.

SEE Eng. Pat. 113,393 of 1917; this J., 1918, 185 A.

Metal [tungsten wire]; Process of treating —. A. Pacz, Cleveland, Ohio, Assignor to General Electric Co. U.S. Pat. 1,280,825, 8.10.18. Appl. 13.4.14. Renewed 18.5.18.

SEE Eng. Pat. 13,549 of 1914; this J., 1915, 803.

Solder or the like and process for preparing the same. A. P. Bevan, Tavistock. U.S. Pat. 1,281,126, 8.10.18. Appl. 9.8.17.

SEE Eng. Pat. 108,916 of 1916; this J., 1917, 1100.

Sulphuric acid [and zinc]. U.S. Pat. 1,278,308. See VII.

Resistance alloy. U.S. Pat. 1,279,252. See XI.

XI.—ELECTRO-CHEMISTRY.

Producer gas cell. Hofmann. See VII.

Electrodeposition of metals. François. See XXIII.

PATENTS.

Furnace; Electric —. S. Peacock, Philadelphia, Pa., Assignor to Haslup and Peacock, Inc., New York. U.S. Pat. 1,279,146, 17.9.18. Appl. 1.3.18.

THE furnace comprises a water-jacketed tube, open at the ends, within which is a hollow resistor surrounded by a heat-shield. Detachable end pieces connected to flanges on the tube carry holders for the resistor and form open chambers communicating with the interior of the resistor, and provided with readily-detachable end pieces to seal them, and with means for exhausting the air from the chambers and the resistor.—B. N.

Furnace; Three-phase electric — and method of operating the same. F. T. Snyder, Oak Park, Ill. U.S. Pat. 1,279,928, 24.9.18. Appl. 11.3.18.

THE furnace is provided with two upper electrodes, a bottom contact, and a source of polyphase current for the formation of two arcs between the electrodes and the bath. A reactance is provided in the path of lowest resistance, of such an amount as automatically to equalise the currents flowing in the different phases of the system.—B. N.

Electrode. F. G. Wheeler, Assignor to Bleach Process Co., Appleton, Wis. U.S. Pat. 1,279,192, 17.9.18. Appl. 21.7.16.

A METALLIC terminal, in the form of a bolt, extends into a screw-threaded recess in the carbon portion of the electrode, and fusible metal is introduced into the space between the bolt and the carbon, the portion of the carbon adjacent to the metal being rendered impervious to the electrolyte or its decomposition products by impregnation with a mixture of asphaltum and a glyceride. The portion of the terminal projecting from the carbon is encircled by a gasket, which lies between the carbon body of the electrode and the internal face of the cell cover, and contact between the gasket and the carbon body to form a liquid-tight joint is secured by means of a nut screwing on to the end of the terminal.—B. N.

Resistance element. J. A. Capp, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,279,252, 17.9.18. Appl. 18.4.16.

A HIGH-RESISTANCE core wire of an alloy of iron (55%), nickel (35%), and manganese (10%) is enclosed within a tubular metallic sheath, with an intervening layer of compact, powdered, insulating material in which the resistance element is embedded.—B. N.

Battery cell; Secondary —. H. Csanyi, New York. U.S. Pat. 1,279,280, 17.9.18. Appl. 27.2.17.

A SECONDARY battery comprises a positive electrode, a container forming the negative electrode, an electrolyte of ammonium and zinc chlorides, and a depolariser of ammonium chloride, graphite, and red lead. On charging the battery, zinc is deposited

at the negative electrode and chlorine liberated at the positive, the chlorine forming lead chloride and peroxide with the red lead. The electrical discharge of the cell produces chemical actions which restore the electrolyte and depolariser to the conditions existing prior to charging.—B. N.

Battery; Storage —. F. Wright, Assignor to Wright Storage Battery Co., Poughkeepsie, N.Y. U.S. Pat. 1,279,508, 24.9.18. Appl., 9.1.14. Renewed 6.2.18.

THE grid of a lead storage battery plate is pasted with a mixture of equal parts by weight of "battery lead" and red lead, moistened with dilute sulphuric acid. The pasted plates are dried at the ordinary temperature, and, before being "formed," are painted over lightly with a small quantity of concentrated sulphuric acid, to make the active material denser and harder and to facilitate the "forming" treatment.—B. N.

Electric furnace. C. H. vom Baur, Douglaston, N.Y., U.S.A. Eng. Pat. 120,444, 10.11.17. (Appl. 16,507/17.)

SEE U.S. Pat. 1,252,633 of 1918; this J., 1918, 156 A.

XII.—FATS; OILS; WAXES.

Palm oils; Rapid hydrolysis of —. Batland. Comptes rend., 1918, 167, 673—674.

THREE samples of palm oil, representing consignments imported into France as food for the Colonial troops, were examined after 4, 3, and 2 months, and found to contain respectively 61.2, 19.4, and 8.3% of free fatty acids, as oleic acid. On keeping for still longer periods the hydrolysis proceeded until the free fatty acids reached 75%.—C. A. M.

PATENTS.

Oils from seeds, beans, nuts, offal, or the like; Apparatus for extracting —. A. McC. Winters. London, Eng. Pat. 120,155, 24.1.18. (Appl. 1412/18.)

THE apparatus consists of several (e.g., three) horizontal extracting chambers connected together in series one above the other. The uppermost chamber is connected with a charging hopper. Each extraction chamber is provided internally with a screw conveyor to lead the material to one end where it falls by gravity to the chamber below, the extract being separated from the material by passage through a screen acting as a false bottom in the lower half of each chamber. Solvent recovered continuously from the oil-bearing extract draining through the screen in each of the three chambers is supplied to the first (upper) chamber, and solvent

similarly recovered from the extracted residue is supplied to the second (intermediate) extracting chamber. The solvent is supplied either through perforations in the shaft of the screw conveyor or preferably through perforations in the upper portion of the extracting chamber, in this case the upper half of the chamber being fitted with a jacket. To recover the solvent, the extracts draining from the chambers are united and allowed to fall by gravity over oppositely inclined baffles and grids or sieves in a chamber into which steam enters at the bottom, the steam and solvent vapour being condensed and the water separated in an apparatus, the upper outlet of which (for recovered solvent) is above the level of entry into the first extraction chamber. The extracted material is delivered by the screw conveyor in the last and lowest of the extracting chambers into a similar solvent-recovery vessel, the oppositely-inclined baffles of which consist of sieves. The volatilised solvent from this latter vessel is condensed and freed from water in apparatus of which the outlet is above the level of entry into the second extraction chamber.

—A. de W.

Hydrogenated-oil compositions. Product containing hydrogenated oil. C. Ellis, Montclair, N.J. U.S. Pats. (A) 1,276,507, (B) 1,276,508, and (C) 1,276,509, 20.8.18. Appls., 6.1.13 (renewed 1.8.16), 21.4.17, and 10.4.18.

(A) A MIXTURE of a hydrogenated animal, fish, or vegetable oil having a "titre" not materially less than 59 and an iodine value not exceeding 25, with carnauba wax or paraffin wax is used for making phonograph records. (B) A mixture of hydrogenated fatty oil (e.g., cottonseed oil) with a non-abrasive mineral substance (e.g., talc, barytes, clay) is used for making phonograph records. (C) Mixtures of hydrogenated fatty oil with non-abrasive powders are used as lubricants, toilet powders, etc., and mixtures with abrasive powders as grinding and polishing compositions.

Hydrogenation; Process of —. A. Schwareman, Assignor to Kellogg Products, Inc., Buffalo, N.Y. U.S. Pat. 1,280,315, 1.10.18. Appl., 20.8.17.

A VERTICAL shaft carrying a number of hollow perforated arms at different levels is rotated in a mixture of oil and "compound gas-occluding catalyst" at a speed sufficient to induce cavitation, hydrogen being supplied through the arms to the cavities immediately on their production.—A. de W.

Catalyst. U.S. Pat. 1,280,314. See I.

Catalytic substances. Ger. Pat. 307,380. See VII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Pine resin. W. Fahrion. Chem. Umschau, 1918, 25, 3—5. Z. angew. Chem., 1918, 31, Ref., 306.

THE resin obtained by the extraction of pine resin residues with caustic soda and acidification of the filtrate is light chocolate-brown in colour, without lustre, friable, and has a faint aromatic herb-like odour. It contains 4% of water and is soluble to the extent of 5.8% in light petroleum spirit, 34.5% in ether, and 55.7% in alcohol. The portion soluble in light petroleum spirit contains, together with neutral substances, some petroleum-soluble derivatives of hydroxyabietic acids. The portions soluble in ether and alcohol are formed by the auto-oxida-

tion of the substances soluble in light petroleum spirit. It is obvious that such a highly oxidised resin cannot in all cases fulfil the functions of normal colophony.—J. F. B.

Rosin from pine scrapings; Process for the recovery of —. W. Schaefer. Chem. Umschau, 1918, 25, 25—26. Z. angew. Chem., 1918, 31, Ref., 306.

PINE scrapings were formerly used to a small extent as an addition to brewers' pitch. Rosin and turpentine oil can be recovered from this material by extraction with solvents, but the process presents considerable disadvantages. The new process proposed consists in heating and emulsifying the crude oleo-resin with water and separating the emulsion from the residue by frothing it over. The product which is floated off is passed into a melting vessel and then into a still from which the turpentine oil is distilled off with the water under vacuum.

—J. F. B.

PATENTS.

Paint-vehicle and method of making same. W. G. Hall, California, Pa. U.S. Pat. 1,279,106, 17.9.18. Appl., 20.9.17.

AN elastic oil suitable as a vehicle for paints is produced by distilling a mixture of about equal parts of "green woods" and crude turpentine. The more volatile constituents are condensed and are mixed while hot with a proportion of the heavier oils remaining in the distillation vessel.

—C. A. K.

Paint; Method of recovering materials from —. J. F. Lostumbo and A. H. Olander, Chicago, Ill. U.S. Pat. 1,279,888, 24.9.18. Appl., 11.2.18.

PAINT refuse, or paint which has become more or less dried, is treated with a solvent, and the oil constituent saponified by the addition of alkali. The solid and liquid portions are separated, and after grinding, the pigments may be utilised again for paint making.—C. A. K.

Paint-dissolver. H. Catlett, Assignor to Schalk Chemical Co., Los Angeles, Cal. U.S. Pat. 1,280,162, 1.10.18. Appl., 24.4.17.

A PAINT dissolver consists of a mixture of trisodium phosphate, 93.25%, and sodium chloride, 6.75%, with sufficient water to dissolve the two constituents.—A. de W.

Plastic compositions. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America. Reissues 14,530 and 14,531, 8.10.18, of U.S. Pat. 1,087,422, 17.2.14. Appls., 8.1.16 and 25.8.18.

SEE Eng. Pat. 3498 of 1911; this J., 1912, 347.

Preparing iron for painting. U.S. Pat. 1,279,101. See X.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Sulphur; Determination of — in vulcanised rubber. H. P. Stevens. Analyst, 1918, 43, 377—378.

ABOUT 0.5 grm. of the sample is digested with 20 c.c. of nitric acid (sp. gr. 1.42) and 0.5 grm. of potassium chlorate, the liquid then boiled for 2 to 3 hours beneath a reflux condenser, and subsequently evaporated to dryness in a basin, after

the addition of 3 grms. of pure magnesium nitrate. The residue is cautiously heated over a naked flame, the presence of the magnesium salt moderating the combustion, and any unburnt carbon is destroyed by digestion with nitric acid and potassium chlorate, and the excess of acid evaporated. After the addition of 10 c.c. of strong hydrochloric acid, the dish is covered with a clock-glass and gently heated until red fumes cease to appear. The liquid is then diluted, filtered, made up to 300 c.c., and heated to boiling on a hot plate, the sulphuric acid precipitated by the addition of 5 c.c. of 10% barium chloride solution, and the precipitate allowed to stand overnight before filtration.—C. A. M.

Isoprene monohydrochloride. Aschan. See XX.

PATENT.

Elastic mass [rubber substitute] and manufacture of the same. E. S. Alt-Cohen, The Hague, Netherlands. U.S. Pat. 1,280,129, 1.10.18. Appl., 14.4.17. SEE Eng. Pat. 103,824 of 1917; this J., 1917, 1140.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins; Estimation of —. New methods and their practical value compared with the hide powder process. R. Lauffmann. Collegium, 1918, 185—190.

A CRITICAL review of the new processes not included in Dekker's "Tannins" (1913). In the methods of Zwick, Vanicek, and Eglén the tannin is estimated by determining the refractivity, acidity, and proportion of total solubles to tans respectively of original and detannised solutions, the figures obtained in each case being multiplied by a factor which is assumed constant for each tannin. Gawalowski (this J., 1916, 187) precipitates the tannin with basic copper acetate, and Levi and Orthmann use a chromium compound as precipitant, a factor being applied to the weight of dry precipitate to obtain tannin content. These conversion factors, however, are not constant for the same material and are useless for application to mixtures of tannins. Kohn-Abrest and Singh and Ghose (this J., 1916, 159) recommend the adoption of inorganic detannisers. These methods seem very arbitrary since the detanniser is so entirely different from hide powder. No materials not in use in the tannery are employed in the hide powder process.—D. W.

Chromium [in tanning liquors]; Influence of iron and organic matter on the iodometric estimation of —. R. Lauffmann. Collegium, 1918, 223—228.

THE author confirms the results obtained by Schorlemmer (this J., 1918, 445A) and Lamb and Harvey (this J., 1916, 1028). Hydroxide precipitates separating out after the peroxide oxidation of chrome liquors adsorb some of the chromate even if filtered off and well washed. If they do not liberate iodine from potassium iodide and are soluble in acid, filtration is unnecessary as they will dissolve in excess acid. Large amounts of organic matter in a chromium solution lead to inaccurate results by the peroxide oxidation method, since they retard the separation of the iodine and obscure the end point. Organic matter has no influence on estimations in which the chromium is oxidised by fusion.—D. W.

Tannage; Quinone —. I. and II. W. Moeller. Collegium, 1918, 71—78, 210—213, 241—242.

ALL compounds of a quinone character are not easily oxidised or reduced. Anthraquinone and its derivatives do not give the ordinary quinone reactions. The quinone characteristics which appear to be missing are present in a latent form. The quinonic or non-quinonic nature of the phlobaphenes cannot be determined by studying their behaviour in ordinary quinone reactions but only by experimental determination of their constitution. Nierenstein, Powarnin, and Koerner have all furnished evidence that tannins have a quinone nature. Active quinonic properties, the tendency to form complex colloids, and tanning properties all seem interdependent. In vegetable tannage the peptiser, a polyphenol, is oxidised; this disturbs the colloid-chemical character of the solution, and peptised phlobaphenes are precipitated along with dark-coloured humins. An intermediate product of this oxidation is always benzoquinone, the quinhydrone of which colours the solution an intense red, to which may be attributed the colour of the phlobaphenes. In the pure benzoquinone tannage the first phase is the oxidation by the quinone of the α -amino-acids in the interfibrillary tissue to aldehydes. The quinone is thereby converted into quinhydrone (red colour) and further into complex colloidal humins (brown) which are the effective tanning agents. Free quinone can never be detected in quinone-tanned leather.—D. W.

Leather formation: Theory of —. I. W. Fahrion. Collegium, 1918, 173—178, 213—214.

A REPLY to Moeller's criticisms on the chemical theory of tannage (Collegium, 1918, 25—40, 61—78, 93—105; J. Soc. Leather Trades Chem., 1918, 188—190). Moeller draws a false analogy between the behaviour of formaldehyde with albumins and with collagen, since the latter is not an albumin but an albuminoid. Water is necessary for Moeller's aldehyde tannage theory; formaldehyde however tans in alcoholic solution. The increased tanning properties of aldehydes containing polymers can be explained by catalysis without the aid of the peptisation theory. Moeller's observation of free aldehyde in pelt after tanning with aldehydes and washing, can be explained by reversible chemical combination or formation of additive compounds. Quinone can tan hide powder by being rubbed together with it in a mortar, without the presence of any solvent. The decomposition products of quinone in aqueous solution are thus proved unnecessary for tanning, hence Moeller's peptisation theory is superfluous and incorrect.

—D. W.

Leather fibre: Elementary structure of —. Principles of molecular physics of leather. W. Moeller. Collegium, 1918, 157—173, 202—210, 230—240.

THEORETICAL deductions from ultramicroscopic observations on hide and leather. The fine fibrils of hide tissue consist of parallel chains of collagen micells with their optical axes all arranged in the direction of the chains, hence the property of anisotropism in hide tissue. Like all organised substances hide tissue consists of two chemically different substances, collagen and its hydrolytic decomposition products. The collagen micell is polyhedral and somewhat elongated. Swelling disturbs the arrangement of the micells. A comparison is drawn between anisotropy in crystals and in the hide tissue which leads to the assumption of a lattice-work arrangement of the micellar chains. The astringent effect of tannins is seen in their action on micellar chains which are subjected to torsion as a result. The optical axes are displaced and the anisotropy disappears. Hide fibres under tension cannot be tanned.—D. W.

PATENTS.

Tanning hides; Process and apparatus for —. V. Quaadvlieg, Keremeos, B.C., Canada. U.S. Pat. 1,280,544, 1.10.18. Appl., 18.9.16.

HIDES are suspended from drums mounted in series in a vat containing tanning solution; the drums can be rotated alternately in opposite directions to secure gradual and uniform bending of the hides, thus opening their pores and ensuring free flow of tanning liquor over their surface.—D. W.

Tanning animal hides; Process for —. Badische Anilin und Soda Fabr. Ger. Pat. 305,855, 11.2.15. Addition to 281,484 (see Addition to Fr. Pat. 443,730; this J., 1914, 209).

SUBSTANCES are claimed which fulfil the conditions specified in the principal patent and contain in their molecule two or more aromatic nuclei, some or all of which are different from the others. Tanning agents which are covered by the present addition comprise the condensation products of 2-naphthol-6-sulphonic acid with benzyl alcohol, of 2,5,7-aminonaphtholsulphonic acid with *p*-toluene-sulphochloride, and of sodium 2-naphthol-6-sulphonate with *p*-cresol.—J. F. B.

Leather, yarns, jute or like materials; Machines for drying —. C. Stephens, Leeds. Eng. Pat. 120,277, 15.11.17. (Appl. 16,779/17.)

By means of a conveyor, the material to be dried is drawn longitudinally through a long horizontal chamber, fitted with two flat sets of steam-heated coils, arranged near the top and bottom of the chamber respectively. Air is blown into the chamber through a tapered inlet duct arranged along the bottom. Baffle-plates direct the air vertically upwards or diagonally, thus ensuring its being continuously heated and reheated as it circulates over the steam coils. An exhaust fan at one end extracts a predetermined proportion of the moist air.—D. W.

XVI.—SOILS; FERTILISERS.

Soil acidity methods. R. E. Stephenson. Soil Sci., 1918, 6, 32—52.

FROM a comparison of the Hopkins, Veitch, Jones, MacIntire, Truog, and Tacke methods of studying soil acidity (this J., 1904, 762; 1915, 1103, 1156; 1916, 699), the author concludes that the Tacke method is the most satisfactory. Pure water is a satisfactory medium for the reaction between the acid soil and the calcium carbonate, although the use of dilute solutions of calcium or sodium chloride hastens the reaction to a limited extent. Concentrated solutions of these chlorides, on the other hand, depress the reaction. The presence of an anti-septic, such as toluene, is not necessary. The most important factors are the duration of the reaction, which should not be less than 5—10 hours; the rate of aeration, which should be maintained at a maximum; the vigour of shaking, which should be thorough. The method is consistent in indicating total acidity, and, in a limited way, also measures toxicity of the soil acids.—W. G.

Potash residues in Hagerstown silty loam soil: Condition of fertiliser —. W. Frear and E. S. Erb. J. Agric. Res., 1918, 15, 59—81.

A LOAM soil in Pennsylvania was selected for study, part of which had received 100 lb. of fertiliser potash biennially for 36 years and the other part had been unmanured, but both had been cropped

alike. The condition of the potash present was determined by several solvents, concentrated hydrochloric acid being used for a strong solvent and $N/5$ acid, distilled water, carbonated water, and ammonium chloride solution for weak solvents. The potash was determined by the platonic chloride method. The total potash in the untreated soil was 3.821%. Concentrated acid dissolved a slightly larger proportion of the total potash from the fertilised than from the unfertilised soil, whereas weak solvents dissolved twice as much from the fertilised as from the unfertilised soil. The $N/5$ acid was the most active of the weak solvents. If a second extraction was made after the first with a weak solvent, the amount of potash dissolved on the second occasion was much less than on the first, but was about equal from the two soils, showing that the potash was more readily available in the fertilised soil. The clayey and non-clayey portions of the soil were also examined separately. The clay contained less potash than the non-clay, and both fractions of the fertilised soil were richer in potash than the corresponding fractions of the unfertilised soil. The crops on the fertilised soil showed little increase over those on the unfertilised soil, owing to the soil being naturally rich in potash. The application of potash, however, caused the amount of potash taken up by the crops to be increased to the extent of 40%. The conclusion reached is that much of the potash applied remained in the surface soil in a highly available condition, but more still in a condition of lower availability; and that the loss by drainage was not great.—J. H. J.

Legume-infecting bacteria: Report on the examination of commercial cultures of —. C. R. Fellers. *Soil Sci.*, 1918, 6, 53–67.

SOME thirty official and twenty unofficial samples of cultures were examined. The culture medium for the plate tests was prepared by adding 12 grms. of mannitol, 2 grms. of monopotassium phosphate, 0.2 gm. of magnesium sulphate, 0.2 gm. of sodium chloride, 0.1 gm. of calcium sulphate, and 1 gm. of calcium carbonate to 1000 c.c. of distilled water and 15 grms. of agar. This was found to be very satisfactory for general plating of all varieties of *B. radicicola*. The purity and general condition of the official samples examined were, generally speaking, very good, only two being classed as "poor" and four as "partly poor." Of the legumes examined, soya beans seemed to be harder to inoculate than most of the common varieties, and for these beans the soil-transfer method of inoculation is recommended. Soil or "muck" cultures are excellent carriers of legume bacteria. The plate method of testing pure cultures gives a good indication of the infecting ability of the organisms, but the results need to be verified by growing the plants themselves and examining the roots for nodules.—W. G.

Legume inoculation: Tests of commercial cultures for —. H. A. Noyes and C. O. Cromer. *Soil Sci.*, 1918, 6, 69–79.

IN the case of sweet clover, inoculation by commercial cultures, or by soil taken from a field where the clover had been recently successfully grown, at a dilution such that seed obtained either its exact proportion of the commercial culture, or its proportion of bacteria in the weight of soil used per acre, gave equally successful results. With soya beans, cowpeas, and hairy vetch, satisfactory inoculation was not secured with either commercial cultures or soil.—W. G.

Seeds; Resistance of — to desiccation. G. T. Harrington and W. Crocker. *J. Agric. Res.*, 1918, 14, 525–532.

SEEDS of wheat, barley, Sudan grass, Kentucky blue-grass, and Johnson grass were dried under varying conditions and for varying lengths of time and it was found that the percentage germination was not materially changed when the seeds were dried to a moisture content of less than 1%. The percentage germination of the two last-named grasses was not affected when the moisture content was reduced to 0.1%, although the vigour of the blue-grass seedlings was greatly reduced. The vigour of the seedlings was further reduced by drying the blue-grass seeds in a vacuum at 100° C. for six hours, but the percentage of germination was not materially affected.—W. G.

Drying plant materials. André. *See* XXIII.

Fertiliser and fertilising. C. Bosch, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,280,650, 8.10.18. Appl., 24.11.14.

SEE Ger. Pat. 286,491 of 1914; this J., 1916, 190. Specific claim is made for a fertiliser containing calcium urea phosphate and ammonia.

XVII.—SUGARS; STARCHES; GUMS.

Sugars; Valuation of raw — from the point of view of the refiner. W. D. Horne. *J. Ind. Eng. Chem.*, 1918, 10, 809–812.

THE efforts which have been made during recent years to elaborate a rough method of standardising raw sugars destined for refining, based on the size and hardness of the grain, the amount of insoluble matter, the reaction, and the odour, in addition to the usual data, such as the polarisation and the ash, are based on assumptions frequently not borne out in practice, and overlook important variations of quality radically affecting the value of the product for refining purposes. On account of the defective nature of some of the raw sugars recently imported into the States, the author has examined the behaviour of the raw sugar when subjected to certain tests that imitate as closely as possible the conditions actually obtaining in the refinery. For example, to obtain an indication of its "adfinability," or the completeness with which the adhering film of molasses can be removed from the crystals, 200 grms. of the sample is mixed into a magna with 92 c.c. of a wash-liquor composed of a saturated solution of the sample itself, made by shaking 100 grms. with 45 c.c. of water for 10 minutes and decanting; this magna is spun in a 5-in. laboratory centrifuge for 2 minutes, and the yield and the polarisation (after drying) of the washed sugar determined. Under these conditions, a good centrifugal raw sugar which during manufacture has not been mixed with "seconds," will polarise about 90.4°, and an ordinary centrifugal sugar, about 99°. If the purity of the washings is below 80°, a deduction from the basic price of the raw sugar may be assessed. Secondly, the behaviour of the raw sugar during defecation and filtration is examined by treating a 45% liquor made from the sample with the minimum amount of acid calcium phosphate and calcium sucrate to produce a clear solution, heating to 190° F. (88° C.), and filtering through a folded cloth in a 3 in. perforated brass cone, the time taken to collect 70 c.c. of the filtrate being noted. Sugars filtering freely

in the refinery will require 5 min. or less in this test, those of medium quality, from 5–10 min., poor samples, 10–15 min., and bad "gummy" samples, 15–20 min., or even longer, and, depending upon this rate of filtration, the deduction to be made from the basic price may be fixed. Thirdly, the readiness with which a raw sugar can be decolorised by animal charcoal is found by dissolving 10 grms. in 30 c.c. of water, adding 0.25 gm. of kieselguhr and 2 grms. of good animal charcoal in powder (which all passes through a 60-mesh sieve), heating gently to boiling point, and filtering through paper, colorimetric tests of the filtrate and of a solution submitted to similar treatment in the absence of the animal charcoal affording the means of comparison. A sugar of average quality will lose in this test about 75% of its colour, and according to the result of the test compared with the result obtained with a standard sample, the deduction to be made from the basic price may be ascertained.—J. P. O.

Cane juice; Role of oxidases and of iron in the colour changes of sugar — F. W. Zerban. *J. Ind. Eng. Chem.*, 1918, 10, 814–817.

PREVIOUS work has indicated that the colouring matter in the sugar cane is composed of chlorophyll, saccharetin, and in the case of dark varieties also anthocyanin. Of these, the first two are insoluble, passing mechanically into the juice during milling, while the saccharetin during the subsequent treatment with lime is rendered soluble, and develops a yellow colour. Anthocyanin is soluble, and imparts a dark colour to juice expressed from cane containing much of it. C. A. Browne (Louisiana Bull., 91, 9) has pointed out the presence in the cane of so-called "tannins," that is, of aromatic compounds giving the well-known colour reaction with ferric chloride, which may not necessarily be true tannins, but may be any of the numerous polyphenols or phenolcarboxylic acids. M. C. Schneller (Louisiana Bull., 157) has suggested that the greyish tint of some sugars and the abnormally dark colour of the less pure factory products may be due to the action of iron salts on the polyphenols. Experiments now carried out by the author with young cane shoots (containing neither chlorophyll nor anthocyanin, but rich in polyphenols) demonstrate that the extracted juice has a dark brown colour, quite unlike the dirty green of raw mill juice. When, however, ferrous sulphate is added to such juice the usual colour of mill juice is reproduced after a short time, showing this to be due to the contact of the juice with the iron of the milling plant. The brown colour formed in the absence of iron is due to the action of a laccase on the polyphenols, and to a small extent also to that of tyrosinase upon the tyrosine of the cane. The dirty green colour of mill juice is attributed to the interaction of the laccase, the polyphenols, and the ferrous salts formed by the action of the organic acids upon the iron of the rollers, the ferrous salts being rapidly oxidised by the oxidases of the cane to the ferric state.—J. P. O.

Decolorising carbon; Preparation of an active — from kelp [for use in sugar refining]. F. W. Zerban and E. C. Freeland. *J. Ind. Eng. Chem.*, 1918, 10, 812–814.

By carbonising kelp rapidly at a comparatively high temperature in such a way that the gases can easily escape, using preferably an open vessel, subsequently heating the product to redness for 2 hours, and afterwards washing it successively with water, hydrochloric acid, and again with water, a preparation more powerful than "Norit" is produced; if the kelp be washed with water before

heating to redness, so as to remove the soluble salts, the results are much less satisfactory. It is suggested that the high nitrogen content of kelp may explain the efficiency of the carbon prepared from it, and it was noticed in every case in which an active product was obtained that Prussian blue was formed on extracting with hydrochloric acid.—J. P. O.

Sucrose; Inversion of — by colloidal silicic acid. A. and A. Mary. *Comptes rend.*, 1918, 167, 644–646.

COLLOIDAL silicic acid, produced by interaction of hydrochloric acid and sodium silicate solutions, is capable of inverting sucrose. The hydrolytic activity appears to depend on the degree of dispersion of the colloid, and is destroyed by coagulation. It increases with rise in temperature to a certain point which is probably determined by coagulative changes. Dialysed solutions lose their activity after a period which varies inversely with their concentration. (See also *J. Chem. Soc.*, Jan., 1919.)—J. H. L.

Xylose; Preparation of — from corn [maize] cobs. C. S. Hudson and T. S. Harding. *J. Amer. Chem. Soc.*, 1918, 40, 1601–1602.

THE authors have previously described the preparation of crystalline xylose from cottonseed hulls (this *J.*, 1917, 730) and now find an even more suitable source in maize cobs. The yield is about 12%. The crushed cobs are boiled for two hours with 7% sulphuric acid; the residue is strained off and the filtrate exactly neutralised with calcium hydroxide, care being taken that the solution never becomes alkaline. The calcium sulphate is removed and the filtrate is decolorised with carbon or bone char after having been made just acid to litmus with phosphoric acid. After concentration under diminished pressure, alcohol is added to the solution; the precipitated calcium sulphate is removed, and the liquid is concentrated to a syrup from which, by suitable treatment with alcohol, the xylose is obtained in the crystalline form.—H. W.

Lactose. Panchaud and Auerbach. See XIXA.

XVIII.—FERMENTATION INDUSTRIES.

Beers; Belgian mashing system suitable for light — G. M. Johnson. *J. Inst. Brew.*, 1918, 24, 237–246.

FOLLOWING an historical sketch tracing the influence of fiscal conditions on the development of Belgian mashing methods, the author describes the "turbid wort" system which is widely employed for the production of full-flavoured light beers. This system, carried out with plant similar to that used in this country, produces dextrinous worts by restricted conversion. The following is a brief outline. A stiff mash is held at 100°–110° F. (38°–43° C.) for 30–45 mins. for peptonisation, and then raised to 120°–125° F. (49°–52° C.) by underletting water at 150°–175° F. (65°–79° C.), after which the turbid wort is drawn off and gradually heated to boiling, with a pause for saccharification. The goods in the tun are meanwhile heated to 158° F. (70° C.) by introduction of hot water, and after saccharification a bright wort is obtained and drawn off to the bright wort copper. The boiling turbid wort is then returned to the tun, so as to raise the temperature of the mash to 167° F. (75° C.), at which saccharification is completed, the clear wort

thus obtained being then added to that already in the bright wort copper. Worts produced by this system do not weaken the yeasts employed. Belgian beers of gravity 1020–1040 produce at least 10 lb. of yeast (as collected at the troughs) per 100 lb. of malt, and often half as much again. It is suggested that the difficulties experienced with yeast in English breweries owing to the reduction of wort gravities, represent a passing phase due to a "displacement" of the characters of the yeast. Pitching yeast is regarded as a mixture of different types, and a reduction of working gravities may favour the predominance of a type previously present in only small proportions, and so change the character of the yeast and the flavour of the beer. To avoid this it is advisable, at each brew, to pitch a small tun of wort of normal gravity and to use the yeast therefrom for the lighter worts.—J. H. L.

Brewery; Tracing infection in the —. H. F. E. Hulton. *J. Inst. Brew.*, 1918, 24, 258–260.

A RATIONAL method of tracing infection deleterious to beer—devised by the author in conjunction with J. L. Baker—which has given good results, is described. Forcing tests are carried out on a series of wort samples taken at numerous stages of brewing from the turn-out of the copper onwards. Samples taken prior to pitching are fermented with a little pure culture yeast before the forcing test. Practical details are given. It has been observed that the liability of wort to infection varies inversely as its gravity.—J. H. L.

Beers; Decarbonation of water used for diluting war —. H. Krumhaar. *Woch. Brau.*, 1918, 35, 121.

THE author discusses the possible effects of carbonates present in waters used for diluting beers. The formation of precipitates by interaction with the salts in the beer is not to be feared, since the concentration of the reacting substances is very low and the temperature also is low. Carbonates will, however, reduce the acidity of the beer by partially neutralising free lactic acid. In some cases, e.g., lager beer, this is not of great importance; but where the character of a war beer depends on the presence of free acid, diluting water rich in carbonates should be decarbonated.

—J. H. L.

Beers; Iron-sickness in thin —. W. Windisch. *Woch. Brau.*, 1918, 35, 69–70, 95–96, 109–110.

IN Germany war beers of very low gravity have proved subject to a malady resembling the iron-sickness of wines, which is due to the formation of ferric tannate. The beers affected become greenish and eventually blackish in colour, and acquire an inky flavour. It is suggested that the iron is probably dissolved by the wort after fermentation owing to contact with naked metal, or is introduced into the beer in the water used in some cases for dilution. Decarbonation by boiling appears to render some waters more "aggressive" towards iron, so that contact of such waters with the metal, during cooling or afterwards, becomes a source of danger. (See following abstract.)—J. H. L.

Beers; Maladies of thin —. W. Windisch. *Woch. Brau.*, 1918, 35, 153–156.

THE war beers of low gravity produced in Germany have been remarkably free from maladies due to micro-organisms. The chief troubles have arisen from tannin-protein turbidity and iron-sickness (see preceding abstract), in both of which tannin

plays an essential part. Some amelioration might be effected by reducing the tannin-content of the beer, e.g., by using a smaller proportion of hops or extracting them with cold water before use, or by promoting the solution of proteins during mashing with a view to the subsequent precipitation of tannins. The fact that the maladies are almost confined to beers of 3% gravity or under, however, probably indicates that these beers are deficient in some protective constituent, which the author conceives to be free acid. He therefore advocates higher acidities in thin beers, and in this connection recommends treatment with lime as the most economical and effective means of decarbonating brewing waters.—J. H. L.

Yeast cells; Diminution in the size of — in thin worts. F. Schönfeld and C. Goslich. *Woch. Brau.*, 1918, 35, 153.

THE production of beers from worts of 3% gravity, as now practised in Germany, was found to yield yeast crops with cells appreciably smaller on the average than those from worts of higher or normal gravity.—J. H. L.

Yeast; Influence of stimulants and of storage under water and beer, on the maltase-activity of —. F. Schönfeld and M. Korn. *Woch. Brau.*, 1918, 35, 129–132.

TREATMENT of bottom-fermentation beer yeast with 1% solutions of monopotassium phosphate for several hours, was found to stimulate the activity not only of the zymase but also of the maltase (see this J., 1918, 161A). The maltase-activity was also increased by treatment with 0.6% solutions of lactic, phosphoric, and tartaric acids, especially by the first named. Yeast stored under water suffered a very slow reduction of maltase-activity, amounting to about 25% in 8 days. Storage under beer produced a more rapid change in the same direction. In general, conditions which affect the zymase of living yeast appear to exert a similar effect on the maltase.—J. H. L.

Wine; Removal of acidity of — by addition of potassium tartrate. W. I. Baragiola. *Schweiz. Ver. anal. Chem.*, May, 1918. *Chem.-Zeit.*, 1918, 42, 515–516.

THE addition of potassium tartrate to reduce the acidity of wine, either by precipitation of the tartaric acid as potassium bitartrate or by simply forming this salt in solution, may alter the relation between the quantities of total tartaric acid and non-volatile acids present in normal wines and thus render impossible the detection of added water and tartaric acid in sophisticated wines.—W. P. S.

PATENTS.

Beer; Brewing — [without malt]. H. Boulard. Paris. Eng. Pat. 119,833, 7.5.18. (Appl. 7660/18.)

THE steeping and boiling of the grain and the addition of hops are all carried out in the same vessel. If the grain itself is not sufficiently acid, a small proportion of an organic acid, e.g. 3% of tartaric acid on the weight of the grain, is also added to assist the conversion of the starch into soluble dextrins, etc. The charge is boiled under a pressure of 4 atm. for about 25 mins., then cooled by water before opening the converter. A further quantity of hops may be added to the converted mash which is again boiled for 20 mins. in the open pan and a short time under pressure. The sterilised wort is saccharified in closed vessels at 38°–40° C. with pure cultures of *Mucor Boulard* No. 5, with a suitable supply of purified air so as

to convert the soluble starch and dextrins into fermentable sugars. The wort is again sterilised, if desired, by boiling and is then cooled and fermented either in separate vats or in the saccharifying vats, preferably by the use of pure cultures of yeast.—J. F. B.

Fermentation; Process for accelerating —. S. Fränkel and J. Fischl, Vienna. Ger. Pat. 307,545, 24.5.16. Int. Conv., 5.5.16.

FERMENTING liquids are treated with alcoholic extracts of embryos of plant seeds, of lower fungi (in particular dried yeast), or of animal embryos such as yolks of eggs.—J. H. L.

Alcohol from sulphite [cellulose waste] liquors; Process of obtaining —. R. H. McKee, Ridgefield Park, N.J., U.S.A. Eng. Pat. 120,520, 15.5.18. (Appl. 8158/18.)

XIXA.—FOODS.

Milk samples; Table for sorting —. L. J. Harris. Analyst, 1918, 43, 375–377.

A TABLE is given by means of which it is possible to see at once, from the sp. gr. and total solids, whether a given sample of milk is above or below the minimum standard of the Board of Agriculture, and in the latter case whether the sample is deficient in fat, solids-not-fat, or both.—C. A. M.

Milk; Refraction of —. J. Pritzker, Schweiz. Ver. anal. Chem., May, 1918. Chem.-Zeit., 1918, 42, 528.

INCREASE of acidity of milk causes a corresponding increase in the refraction of the milk serum, the increase being due to solution of calcium phosphates by the lactic acid. When the quality of a milk is judged from its refraction, the acidity of the sample should be determined and taken into account.—W. P. S.

Lactose [in milk]; Refractometric determination of —. L. Panchaud and E. Auerbach. Schweiz. Ver. anal. Chem., May, 1918. Chem.-Zeit., 1918, 42, 528.

COMPARATIVE determinations of lactose in milk by means of the refractometer and by Allihn's method yielded concordant results, the differences not exceeding 0.03%. In the case of sour milk with an acidity of 2%, the result found by the refractometer was 0.7% too high; this was due to the conversion of the lactose into lactic acid, which has a higher refractive index. Milk from cows with diseased udders also gave high results for lactose when examined with the refractometer; this milk contained a high percentage of chlorides and of proteins which were not precipitated by calcium chloride.—W. P. S.

Butter; Analysis of —. P. Erculisse and H. Dackweiler. Ann. Chim. Analyt., 1918, 23, 225–234.

THE authors determine the saponification value, the "silver value," and the "magnesium value" of the fat, and from these results calculate the

Reichert-Meissl, Polenske, and Hehner values of the fat, or figures which correspond with these values. This indirect method is stated to be more accurate than the usual direct method of determining the values. The saponification value is determined on 4 grms. of the fat; the neutral soap is then diluted to a definite volume and an aliquot portion of the solution is treated with an excess of N/10 silver nitrate solution, filtered, and the excess of silver titrated in the filtrate. All fatty acids, with the exception of butyric acid, are precipitated by the silver nitrate, and from the result is calculated what the authors term the true Reichert-Meissl value. Similarly, magnesium sulphate precipitates all acids higher than C₁₂. The Polenske value calculated from the result of the magnesium precipitation is higher than the value determined in the usual way. Results of the examination of one sample of butter are recorded.

—W. P. S.

Witgatboom, a substitute for chicory. J. McCrae and A. Kloot. Analyst, 1918, 43, 373–374.

THE roots of four of the S. African trees known as "witgatboom" (white-hole tree) are used as chicory substitutes, viz., *Boscia transvaalensis* (most commonly used in the Transvaal), *B. rehmanni*, *Marua pedunculata* (Cape Province), and *Capparis albitrunca*. Commercial roasted samples showed under the microscope characteristic triangular pitted cells. On analysis they gave the following results:—Sp. gr. of 10% decoction, 1.0118 to 1.0244; total water-soluble matter, 31.0 to 68.5; ash in aqueous extract, 3.5 to 5.5; total ash, 4.3 to 6.9; and ash insol. in HCl, 1.1 to 1.7%. Results obtained with genuine samples of the roasted roots of (A) *Boscia transvaalensis* without the hard core; (B) the same root containing the core; and (C) *Marua pedunculata* are tabulated.—C. A. M.

Silage; Chemistry of sweet clover — in comparison with alfalfa [lucerne] silage. C. O. Swanson and E. L. Tague. J. Agric. Res., 1918, 15, 113–132.

LUCERNE, sweet clover, and a mixture of sweet clover and corn (maize) meal were placed in three series of bottles which were examined after increasing intervals of time. Good silage was produced in each case. Water and alcohol extracts were made and examined for acidity by electrometric and titration methods. It was found that the loss of weight in conversion into silage was approximately 1%. The titration acidity of the alcoholic extracts was greater than that of the water extracts, owing to the colouring matter extracted by the alcohol obscuring the end point, for when the electrometric method was used there was no appreciable difference between the acidities of the two extracts. Most of the acidity was developed in the first 15 days. The addition of maize meal to the sweet clover increased the production of acid. The amino-nitrogen was the same in the two extracts, but the lucerne silage yielded much more than the sweet clover silage. The amide-nitrogen formed about one-half of the total nitrogen. The solvent action of the water and the alcohol was about the same, two-thirds of the total nitrogen being extracted in each case. The practical conclusion is that silage can be made more easily from sweet clover than from lucerne.

Cinchona alkaloids. I. Cupreine, hydrocupreine, and their methyl and ethyl esters. G. Giemsa and J. Halberkaun. Ber., 1918, 51, 1325—1333.

Dihydrocupreine, prepared by the addition of hydrogen to cupreine in the presence of a palla-

dium or nickel catalyst, has m.p. 201° C. Hesse (Annalen, 1887, 241, 281) gives 168°—170° C. Cupreine yields methylenepreine (quinine) by methylation by methyl sulphate or diazomethane. Methylidihydrocupreine is obtained by the catalytic reduction of quinine or by the methylation of dihydrocupreine. Ethyldihydrocupreine is prepared by similar methods.—C. S.

Cinchona alkaloids. XX. Synthesis of quinotoxines.

P. Rabe and K. Kindler. Ber., 1918, 51, 1360—1365.

N-Benzyldihydrocinchonoleufone, prepared from benzyldihydrocinchonotoxine, is converted into its ethyl ester, $C_{27}H_{27}O_3N$, b.p. 256° C. at 13 mm., which reacts with ethyl chlorohydrate and sodium ethoxide to form a substance, doubtless the β -ketonic ester, the hydrolysis of which by boiling 15% hydrochloric acid yields dihydrocinchonotoxine (dihydrocinchonine). Since dihydrocinchonotoxine has been converted into dihydrocinchoninone and the latter can be reduced to dihydrocinchonine and dihydrocinchonidine (future communication), the construction of cinchona alkaloids from derivatives of the quinoline and piperidine series has been accomplished. (See also J. Chem. Soc., Jan., 1919.) —C. S.

Strychnine alkaloids. XXIV. Cause of the violet reaction of cacotheline and of nitro-compounds of the brucine series allied to it. H. Leuchs. Ber., 1918, 51, 1375—1389.

The methonitrate of the cacotheline base, $C_{21}H_{21}O_7N_3 \cdot CH_3 \cdot NO_2$, obtained by the action of nitric acid on methylbrucine, is a nitrated quinone, since it is converted into the oxime, $C_{22}H_{25}O_7N_4Cl$, $2H_2O$, yellow needles, of the methochloride of the cacotheline base by the action of hydroxylamine hydrochloride. It is converted by a hot aqueous solution of sodium bisulphite into a methosulphite of the cacotheline base, $C_{21}H_{21}O_7N_3 \cdot CH_3 \cdot SO_3H$, deep violet prisms. The latter contains the sulphite group in complex union, because sulphur dioxide is not eliminated by the action of strong acids, and is a nitrated quinol, since it is converted by nitric acid into a reddish-yellow methosulphite, $C_{20}H_{19}O_7N_3 \cdot CH_3 \cdot SO_3H$, which is reconverted into the violet compound by sulphurous acid or other reducing agents. Apart from their acidic groups, the methonitrate and the violet methosulphite are isomeric. The conversion of the former into the latter is, in the author's opinion, a case of intramolecular reduction. (See also J. Chem. Soc., Jan., 1919.) —C. S.

Nitro- and amino-arylarsonic acids. W. A. Jacobs, M. Heidelberger, and I. P. Roff. J. Amer. Chem. Soc., 1918, 40, 1580—1590.

The preparation of a number of nitro- and amino-arylarsonic acids is described; the nitro-compounds were generally obtained by Bart's method (Ger. Pat. 250,264; Eng. Pat. 568 of 1911; this J., 1911, 1087), in which a diazo- or isodiazogroup is replaced by the arsenic acid residue. The procedure is particularly serviceable with *o*- and *p*-nitroamines; with *m*-nitroamines, on the other hand, the yields are poor though better with *m*-nitrotolylamines than with *m*-nitraniline. Reduction of the nitro- to the amino-group without disturbance of the arsenic acid residue was conveniently effected with cold alkaline ferrous hydroxide solution (compare Benda, Ber., 1911, 44, 3302). The following compounds have been prepared by these methods:—*o*-nitrophenylarsonic acid, $NO_2 \cdot C_6H_4 \cdot AsO(OH)_2$, m.p. 235°—240° C. with decomp. (compare Bart, loc. cit.); *o*-aminophenylarsonic acid or *o*-arsanilic acid (compare Benda,

loc. cit.), needles, m.pt. 153° C.; *m*-aminophenylarsonic acid or *m*-arsanilic acid (compare Berthelm, this J., 1908, 622; Berthelm and Benda, Ber., 1911, 44, 3297), colourless rhombic prisms, m.pt. 213°—215° C. (decomp.); *p*-nitrophenylarsonic acid (compare Hart, *loc. cit.*), pale yellow aggregates of minute leaflets which do not melt below 275° C.; *p*-aminophenylarsonic acid (*p*-arsanilic acid); 2-nitro-*p*-tolylarsonic acid, faintly yellow minute rods, m.pt. 255°—260° C. (decomp.); 2-amino-*p*-tolylarsonic acid, colourless needles, m.pt. 180° C. after softening and darkening; 6-nitro-*o*-tolylarsonic acid, pale yellow needles, decomposing at 228°—230° C.; 6-amino-*o*-tolylarsonic acid, rosettes or plates, decomposing at 175°—180° C.; 5-nitro-*p*-tolylarsonic acid (compare Michaelis, Annalen, 1902, 320, 321), cream-coloured needles, which do not melt below 285° C.; 5-amino-*p*-tolylarsonic acid, microscopic needles, m.pt. 172°—175° C.; 5-nitro-*o*-tolylarsonic acid (compare Karrer, Ber., 1915, 48, 311), m.pt. 261°—263° C. after melting or changing in appearance at about 225° C. according to the rate of heating; 5-amino-*o*-tolylarsonic acid, cream-coloured prisms, decomposing at 235°—245° C.; 4-nitro-*o*-tolylarsonic acid, minute needles, m.pt. 255°—240° C. (decomp.); 4-amino-*o*-tolylarsonic acid, microscopic needles, decomposing at 222°—224° C. (Benda and Kahn, Ber., 1908, 41, 1675, give 180° C.); 4-nitro-*p*-xylylarsonic acid, yellow crystals, m.pt. 290° C. (decomp.), which is not identical with the substance obtained by Michaelis (*loc. cit.*) by the nitration of *p*-xylylarsonic acid; 4-amino-*p*-xylylarsonic acid (compare Benda and Kahn, *loc. cit.*), colourless platelets, m.pt. 213°—214° C. (decomp.); 2-amino-4-hydroxyphenylarsonic acid, decomposing at 290° C. after darkening and softening at about 220° C.—H. W.

Diethylaminoacetylsalicylic acid; Synthesis of derivatives of —, F. L. Hahn and M. Loos. Ber., 1918, 51, 1436—1447.

A NUMBER of substances were prepared partly with the object of obtaining a compound having certain advantages over aspirin. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Glycero-phosphoric acid; Synthesis of optically active —, E. Abderhalden and E. Eichwald. Ber., 1918, 51, 1308—1312.

PROSPEROYL chloride is added to a solution of *d*-α-bromohydrin in dry pyridine at a temperature below -10° C. The bromine is removed by means of lithium hydroxide and the product is isolated as nearly pure lithium *d*-glycero-phosphate, $\text{HO} \cdot \text{CH}_2 \cdot \text{CH}(\text{OH}) \cdot \text{CH}_2 \cdot \text{O} \cdot \text{PO}(\text{OLi})_2$, $[\alpha]_D^{18} = +3.51^\circ$ in aqueous solution. Lithium *l*-glycero-phosphate has $[\alpha]_D^{18} = -3.02^\circ$. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Propyleneglycol; Optically active — and optically active β-hydroxybutyric acid, E. Abderhalden and E. Eichwald. Ber., 1918, 51, 1312—1322.

3-CHLORO-*n*-PROPYLAMINE was resolved by *d*-tartaric acid and the *d*-tartrate, m.pt. 109.5° C., $[\alpha]_D^{18} = +36.72^\circ$ (in water), was converted by sodium nitrite into *d*-β-chloro-*n*-propanol, b.pt. 40°—41° C. at 15 mm. The chloropropanol was converted by aqueous potassium hydroxide at 50°—70° C. into *d*-propylene oxide, b.pt. 36.5°—38° C., $[\alpha]_D^{18} = +12.72^\circ$, which by treatment with anhydrous formic acid and subsequent hydrolysis by 15% hydrochloric acid yielded *d*-propyleneglycol, b.pt. 95° C. at 15 mm., $[\alpha]_D^{18} = +13.71^\circ$ (in water). *d*-Propylene oxide has been converted through *l*-β-bromo-isopropyl alcohol and *l*-β-hydroxybutyronitrile into the biologically important *l*-β-hydroxybutyric acid, and *d*-β-chloro-*n*-propanol has been converted

through *l*-α-chloropropionic acid into *l*-alanine, and thus the configurative relations of these substances have been established. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Isoprene; Monohydrochloride of —, O. Aschan. Ber., 1918, 51, 1303—1307.

THE isoprene monohydrochloride described by Bouchardet in 1879 was almost certainly *tert*-isomyl chloride. Isoprene monohydrochloride, prepared from carefully purified isoprene obtained from *d*-limonene, has b.pt. 109° C. and sp. gr. 0.9335 at 20° C. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Formic acid; Reducibility of —, K. A. Hofmann and H. Schibsted. Ber., 1918, 51, 1389—1398.

IN spite of all statements in the literature to the contrary, the authors have never obtained more than 4% of the expected yield in their attempts to reduce formic acid to formaldehyde and methyl alcohol by hydrogen under the most diverse experimental conditions. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Formaldehyde and methyl alcohol; Production of — from formates, K. A. Hofmann and H. Schibsted. Ber., 1918, 51, 1398—1418. (Compare preceding abstract.)

METALLIC formates are able, to a degree dependent on the nature of the particular metal, to yield formaldehyde according to the equation $2\text{H} \cdot \text{CO}_2\text{M} = \text{M}_2\text{CO}_3 + \text{CH}_2\text{O}$. The temperature at which a distinct and sustained evolution of gas from the formate begins is in general higher the more strongly basic is the metallic oxide. For the following formates the temperatures are: Cu, 170° C.; Pb, 195°—200° C.; Ni, 210° C.; Zn, 240°—245° C.; Fe, 245°—250° C.; Mn, 295°—300° C.; Ba, 325° C.; Ca, 335° C.; Mg, 340°—345° C.; Sr, 355° C.; Li, 355° C.; Na, 355° C.; K, 375° C. The formaldehyde produced experiences, according to the nature of the metalliferous residue, diverse transformations, of which the most important is its conversion into methyl alcohol and formic acid. The vapour of formic acid, with or without hydrogen, yields carbon monoxide and steam or carbon dioxide and hydrogen when passed over a chemically unchangeable catalyst at a sufficiently high temperature. Considerable quantities of formaldehyde and methyl alcohol are produced, however, if the catalyst and the temperature of reaction are so selected that the formation of a formate is rendered possible. Zinc oxide and thoria are the best catalysts for this purpose. (See also J. Chem. Soc., Jan., 1919.)—C. S.

Silver; Recovery of — from albumose-silver solutions. Methods for the analysis of these solutions, G. Maue. Chem.-Zeit., 1918, 42, 512—515.

LARGE quantities of 0.1% albumose-silver solutions are now used in certain hospitals and the recovery of the silver from the used solution is of importance. The following method is recommended for the purpose:—360 litres of the waste solution is treated with 60 grms. of sulphuric acid mixed with 200 c.c. of water, and 19 grms. of sodium chloride dissolved in 200 c.c. of water is added; the precipitate is allowed to settle, collected on a filter, dried, and fused with a mixture of potassium carbonate, 30, sodium carbonate, 30, and potassium nitrate, 15 grms. While still fluid, the mixture is poured into cold water and the metallic silver is collected. The cost of treating 360 litres of the solution is estimated to be M.0.12; the weight of silver recovered is 336 grms. having a

value of M.1375. An alternative method consists in precipitating the silver with ammonium thiocyanate in the presence of sulphuric acid; the silver thiocyanate is then treated as described. The estimated cost in this case is M.023. To determine silver in albumose-silver solution, the silver is first precipitated as metallic silver (by reduction) or as some insoluble salt which is fused with alkali carbonate and nitrate, and the silver is then dissolved in nitric acid and titrated. Methods using the following reagents yield accurate results: Lactose and sodium hydroxide, tannin, hydrochloric acid, potassium bromide and sulphuric acid, potassium iodide and sulphuric acid, ammonium thiocyanate and nitric acid, potassium ferrocyanide and acetic acid. Reduction with ferrous sulphate, or oxidation of the organic matter with permanganate, gives low results.—W. P. S.

Ethylamine and diethylamine; Preparation of —. E. A. Werner, *Chem. Soc. Trans.*, 1918, 113, 899–902.

FIVE litres of 90% alcohol containing 430 grms. of ammonia was treated with 200 grms. of ethyl bromide and at intervals of 2 days eight diminishing quantities of ethyl bromide were added, the last quantity being 66 grms. and the total quantity 1186 grms. On the sixteenth day the solution was concentrated until nearly all the ammonium bromide had separated; it was then evaporated to dryness at 130°C. and the diethylammonium bromide, containing only about 5% of triethylammonium bromide, was separated from the ethylammonium bromide by extraction with chloroform. Diethylamine quantitatively displaces the tertiary amine from an alcoholic solution of triethylammonium chloride, and, similarly, ethylamine quantitatively displaces diethylamine. The three amines were separated by fractional addition of sodium hydroxide to an aqueous solution of the chlorides. Triethylamine behaved as the weakest base and the ethylamine as the strongest, behaviour which is contrary to the commonly accepted view.—C. S.

Phenol [carvacrol] from the leaves of Coleus amboinicus, Lour (C. carnosus, Hassk). F. Weehuizen, *Rec. Trav. Chim. Pays-Bas*, 1918, 37, 355–356.

THE fresh herb, *Coleus amboinicus*, Lour. gives a small yield of essential oil, 25 c.c. from 120 kilos., which contains a phenol identified as carvacrol.—W. G.

Odorous substances; Spontaneous transformation of solutions of — to a colloidal state by exposure to ultra-violet light. H. Zwaardemaker and F. Hogewind, *Proc. K. Akad. Wetensch. Amsterdam*, 1918, 21, 151–157.

SOLUTIONS of odorous substances in water, glycerol, or paraffin on keeping slowly pass into colloidal solutions which strongly exhibit the Tyndall effect. The change is accelerated by light, and particularly by ultra-violet light; thus a change which is effected in 30 minutes by means of ultra-violet light requires several weeks in daylight. (See also *J. Chem. Soc.*, Jan., 1919.)—J. F. S.

Rhubarb juice; Composition of —. A. A. Besson, *Schweiz. Ver. anal. Chem.*, May, 1918, *Chem.-Zeit.*, 1918, 42, 527–528.

THE following results were obtained on the analysis of 7 samples of rhubarb juice:—Total solids, 23.45 to 35.25; reducing substances, 4.5 to 12.7; ash,

4.1 to 6.9; ammonia-nitrogen, 0.13 to 0.45; protein-nitrogen, 0.05 to 0.22; oxalic acid, 2.11 to 3.53; tannin, 0.05 to 0.38 gm. per litre; total acidity 154.5 to 222.0 c.c., alkalinity of ash 42.0 to 82.8 c.c., and free organic acids 150.4 to 217.3 c.c. of N/1 solution.—W. P. S.

Trypanosomes; Improved method for recovering — from the blood of rats for antigen purposes in connection with complement fixation. F. H. Reynolds and H. W. Schoening, *J. Agric. Res.*, 1918, 14, 573–576.

THE blood of rats which have been inoculated with trypanosomes for the purpose of the preparation of an antigen is collected in sodium citrate solution, and the mixture is strained through muslin and centrifuged for 20 mins. at 2000 revolutions per min. The clear liquid is drawn off and centrifuged again to recover any trypanosomes present. The first deposit of red corpuscles and trypanosomes is agitated with distilled water for 20 mins. in order to take the corpuscles completely. The liquid is then centrifuged for half an hour, the red solution drawn off, and the deposit of trypanosomes is agitated with physiological salt solution and centrifuged again. The supernatant fluid is discarded, and preserving fluid is added to the deposited trypanosomes and stirred to produce a uniform suspension, which is then stored on ice. Experiments showed that the use of distilled water to take the corpuscles had no detrimental effect on the antigen value of the trypanosomes, and the keeping qualities of the product were improved.—J. H. J.

Mercury as a contact poison. G. Bredig, *Ber.*, 1918, 51, 1477.

THE poisoning of catalysts by mercury (compare Paal and Hartmann, this J., 1918, 560 A) has been previously noticed by Bredig and Berneck (*Z. physik. Chem.*, 1899, 34, 327; compare this J., 1900, 1155) and others.—C. S.

PATENTS.

Amyl acetate; Separation of — from chloro-hydrocarbons. G. G. Oberfell and H. T. Boyd, Homer, Ohio, Assignors to The Ohio Fuel Supply Co., Pittsburgh, Pa. U.S. Pat. 1,278,198, 10.9.18. Appl., 22.1.18.

SYNTHETIC amyl acetate and its homologues, prepared by the esterification of chloro-hydrocarbons of the olefine or naphthene series, are purified by first fractionally distilling the esterified product, thereby separating the unsaturated olefine hydrocarbons formed in the reaction, then treating the residue formed by the decomposition of the chloro-compounds during esterification with sulphuric acid, which dissolves the amyl acetate and its homologues, leaving the other constituents, then separating the two layers and treating the amyl acetate solution to separate the amyl acetate and its homologues from the sulphuric acid.—J. F. B.

Camphylcarbinal; Production of —. H. Rupe, Basle, Ger. Pat. 307,357, 3.6.16.

ALCOHOLIC, aqueous alcoholic, or acetic acid solutions of oxymethyleneamphor, or aqueous solutions of its neutral alkali salts, are reduced by hydrogen under normal pressure, in presence of finely divided nickel or cobalt.—J. H. L.

Catalytic substances. Ger. Pat. 307,380. See VII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[Photographic] developing agents; Examination of organic —. H. T. Clarke. Communication from Eastman Kodak Research Laboratory. Brit. J. Phot., 1918, 65, 499—503.

A SCHEME is outlined for the identification of 16 of the commoner developing agents, arranged in 4 groups according to their solubility in water, ether, and alcohol. Detailed descriptions are given of the characteristic reactions of each for qualitative examination and methods for quantitative estimation of most of them both singly and in mixtures. A number of typical analyses of developers actually on the market are also given showing in some cases a very considerable deviation from a reasonable standard of purity. For example a developer containing over 50% of lead chloride; a developer "identical to metol" containing 52% of quinol and only 32.8% *p*-methylaminophenol sulphate; metol substitutes containing respectively 33% of sucrose, 25.5% of pyrogallol with 73.4% of sodium sulphite, 85% of ammonium *p*-toluenesulphonate, and in two cases no methylated product at all. Numerous other adulterants were found, a list of 25 being given including starch, sucrose, citric acid, and various inorganic salts.—B. V. S.

PATENTS.

Colour photography. F. E. Ives, Philadelphia, Pa. U.S. Pat. 1,278,667, 10.9.18. Appl., 20.2.17.

Two colour-selection negatives, *e.g.* red and green, are first obtained. From the "red" negative is then obtained a blue-green positive and from the "green" negative a diapositive in some suitable colour contrasting with the blue-green. The blue-green film is then re-sensitised, exposed through the diapositive in register with it, and the image toned red.—B. V. S.

Colour photograph or film and method of producing the same. F. E. Ives, Philadelphia, Pa. U.S. Pat. 1,278,668, 10.9.18. Appl., 9.10.17.

A TRANSPARENT support provided with a film containing a sensitive silver salt is exposed through the support, developed, etc., then re-sensitised, exposed on the face, and developed to form a blue-green image. The silver image at the back is then copper-toned to a red colour.—B. V. S.

Coloured [photographic] images; Process of producing —. E. R. Bullock, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,279,248, 17.9.18. Appl., 7.3.17.

A METALLIC image is oxidised and then reduced by an organic compound which forms, in the reduction process, an insoluble coloured compound. For example, a silver image is converted to the ferricyanide by the action of potassium ferricyanide and permanganate and then reduced by benzidine chloride. The silver salt is removed by fixing in "hypo" with the addition of a small quantity of an oxidising agent such as chromate.—B. V. S.

Tinting process [for photographs] and product thereof. J. I. Crabtree, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,279,276, 17.9.18. Appl., 25.1.17.

THE gelatin of a photograph with an opaque image, such as silver, is tinted by treatment first with a solution of a suitable metal and then with a solution of a suitable precipitant, the coloured precipitate formed in this way being so finely divided as to be practically transparent.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Explosives Physical Laboratory of the Bureau of Mines; Methods for routine work in the —. S. P. Howell and J. E. Tiffany. U.S. Bureau of Mines. Tech. Paper 186, 1918. 63 pages.

DESCRIPTIONS are given of the methods used for determining the suitability of explosives for use in gaseous and dusty coal mines and in metal mines, tunnels, quarries, and engineering operations.

PATENTS.

Propellant-explosives; Gelatinised — and process of preparing same. F. L. Nathan, W. Rintoul, and F. Baker, Stevenson, Assignors to Nobel's Explosives Co., Ltd., Glasgow. U.S. Pats. 1,280,278 and 1,280,279, 1.10.18. Appl., 26.2.14.

SEE Eng. Pats. 12,743 and 12,746 of 1912; this J., 1913, 991.

Explosive. A. Segay, Ware. U.S. Pat. 1,280,563, 1.10.18. Appl., 7.8.17.

SEE Eng. Pat. 113,083 of 1917; this J., 1918, 390 A.

XXIII.—ANALYSIS.

Silver-asbestos, lead chromate-asbestos, and lead-peroxide asbestos [for use in combustions]. O. Binder. Chem.-Zeit., 1918, 42, 522.

THE use of silver-asbestos is recommended in place of silver foil for the removal of chlorine in combustion analyses. It is prepared by reducing ammoniacal silver nitrate solution with metallic zinc, washing and drying the finely-divided precipitated silver, and then mixing it with ignited asbestos. A mixture of asbestos and lead chromate or lead peroxide is useful for the absorption of sulphur compounds.—W. P. S.

Drying of plant materials at different temperatures. G. André. Bull. Soc. Chim., 1918, 23, 430—437.

THE loss of water from plant materials, such as leaves or buds, when dried at 120° C. in a current of dry air, proceeds rapidly at first but soon slows down and there is a very slow but continuous loss over a long period of time. There is very little loss of organic matter during the drying at 120° C. in a current of dry air.—W. G.

Metals; Electrolytic determination of — without the use of an external current. M. François. Comptes rend., 1918, 167, 725—727.

A SELF-CONTAINED cell may be constructed by placing a strip of nickel across the top of a platinum crucible and suspending a zinc rod, 5 mm. in diam., from this strip; the lower end of the rod extends nearly to the bottom of the crucible. It is necessary to amalgamate the zinc rod at least 24 hrs. before it is used and during use it is provided with a filter-paper jacket held in position by cotton thread. For the deposition of silver or gold, the salt is dissolved in 2 c.c. of water in the crucible and 9 c.c. of 10% potassium cyanide solution, 5 c.c. of potassium hydroxide solution (36° B., sp. gr. 1.332), and 2 c.c. of ammonia (22° B., sp. gr. 1.18) are added. In the case of mercury the crucible should contain 20 c.c. of 10% sulphuric acid and 0.5 gm. of potassium iodide. The metals are deposited on the surface of the platinum crucible; the time required is 24 hrs., and the deposition is quantitative.—W. P. S.

Germanium; Separation of — from arsenic, by distillation of the chloride in the presence of a chromate. P. E. Browning and S. E. Scott. Amer. J. Sci., 1918, 46, 663—665.

ANOTHER modification of Buchanan's method (see this J., 1917, 1196) is described, chromic acid being used in place of permanganate or chlorate to oxidise the arsenious acid. The substance containing germanium oxide and not more than 0.25 gm. of arsenious oxide is warmed in a flask with 5 c.c. of 10% potassium bichromate solution and a few drops of sulphuric acid. About 10 c.c. of concentrated hydrochloric acid is then added and the mixture distilled; a current of carbon dioxide is passed through the apparatus during the distillation to facilitate distillation of the volatile germanium chloride and to remove any chlorine which might result from the action of the hydrochloric acid on the excess of chromic acid. The distillate is tested with hydrogen sulphide, a white precipitate of germanium sulphide being obtained in the presence of as little as 0.0005 gm. of germanium oxide.—W. P. S.

Nitrogen; Pregl's micro-estimation of —. H. Fischer. Ber., 1918, 51, 1322—1325.

UNTRUSTWORTHY results are obtained when the nitrogen in difficultly combustible substances is estimated by the micro-Dumas method (compare Kraemer, this J., 1918, 526A), and the author now uses only the original Pregl method ("Die quant. org. Mikroanalyse," 1917). The latter method is preferred to the Lassaigne test in detecting nitrogen in rare or very valuable organic compounds.—C. S.

Davis and Twigg. Reversible regenerative gas-fired furnaces. 20,456. Dec. 9.

Dunér. Filtering device for centrifugal separating machines. 19,577. Nov. 27. (Sweden, 22,117.)

Frey and Henz. Suppressing formation of froth or scum when boiling liquids. 20,169. Dec. 5. (Switz., 6,12,17.)

Kestner Evaporator and Engineering Co., and Reavell. Apparatus for cooling gases. 20,044. Dec. 4.

King and Rawson. Calcination. 20,533. Dec. 10.

Lamb and Pennington. 19,386. See II.

MacDonald. Production of extracts from vegetable materials. 20,355. Dec. 7.

Magrath. Apparatus for treating liquids with gases. 20,270. Dec. 6.

O'Brien. Continuous fractional distillation. 20,765. Dec. 13.

Pluperfect Refrigeration Co., and Ryder. Apparatus for making ice. 20,321. Dec. 7.

Wake. Grinding, crushing, and pulverising mills. 19,770. Nov. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

12,291 (1917). Goyvaerts, Beequevort, and Bossut. Apparatus for fractional distillation of mixtures of liquids not miscible with water. (120,940.) Dec. 11.

16,355 (1917). Brooke. See VII.

17,064 (1917). Bates and Walker. Conveyor and its application to drying, mixing, screening, etc. (120,761.) Dec. 4.

17,982 (1917). Smith. See II.

18,349 (1917). Burns. See XI.

18,626 (1917). Hunter. Dry kiln. (120,809.) Dec. 4.

6062 (1918). Darasse. See VII.

6305 (1918). Schar. Grinding-mills. (115,424.) Dec. 18.

8011 (1918). Turner. Fractional or destructive distillation. (120,851.) Dec. 4.

8464 (1918). Carrier, and Carrier Engineering Corporation. Drying, conditioning, and regulating the moisture content of hygroscopic materials. (121,060.) Dec. 11.

12,966 (1918). Wilson. Filters. (120,867.) Dec. 4.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Burnett. Apparatus for washing coal etc. 19,442. Nov. 26.

Chrystal. Producer gas plants. 19,940. Dec. 3.
Clere. Gas generators. 20,098. Dec. 4. (Fr., 1,12,17.)

Climie and Lees. Gas producers. 20,390. Dec. 9.
Climie and Lees. Gas-producing plant. 20,391, 20,392. Dec. 9.

Colson. Apparatus for synthetic production of gas from coal. 19,378. Nov. 25. (Fr., 26,11,17.)

Dalton. Artificial fuel composition and process. 19,615. Nov. 28. (U.S., 12,1,18.)

Davis and Twigg. 20,456. *See* I.

Dickinson (Ashworth). Apparatus for distilling or cracking heavy oils etc. 20,531. Dec. 10.

Findlater. Apparatus for continuous separation of paraffin wax from oil. 19,639. Nov. 28.

Ionides. Heating gaseous fluids. 19,827. Nov. 30.

Iverson. Gas-producers. 20,654. Dec. 11.

Lamb and Pennington. Treatment of coal, water, etc., and removal of substances therefrom. 19,386. Nov. 25.

Marks (Soc. Franco-Belge de Fours à Coke). Treatment of gases, producing distillation, coking, or gasifying coal etc. 19,677. Nov. 28.

Murphy. Manufacture of fuel from coke etc. 20,225. Dec. 6.

Smith. Gas-producers. 19,697 and 20,436. Nov. 28 and Dec. 9.

Temple. Means for gasification of coal, shale, etc. 20,880. Dec. 14.

Umsted. Manufacturing gas and obtaining by-products. 20,002. Dec. 3.

Westinghouse Lamp Co. Filaments of highly refractory metal. 19,460. Nov. 26. (U.S., 19,12,17.)

Westinghouse Lamp Co. Filaments. 19,595. Nov. 27. (U.S., 19,12,17.)

COMPLETE SPECIFICATIONS ACCEPTED.

15,445 (1917). Walster and Walster. Generating coal gas in retorts. (121,146.) Dec. 18.

16,879 (1917). Baker. *See* VII.

17,740 (1917). Bamber. Producer-gas plants. (121,161.) Dec. 18.

17,858 (1917). Penhale. Motor fuel. (120,792.) Dec. 4.

17,982 (1917). Smith. Cooling, cleansing, and filtering devices for gas. (121,177.) Dec. 18.

2445 (1918). Hayashi and Kaisha. *See* XVII.

6801 (1918). Doyle. Raising and drying peat. (120,850.) Dec. 4.

8011 (1918). Turner. *See* I.

9977 (1918). Zwilling. Converting beehive coke ovens into by-product ovens. (121,085.) Dec. 11.

13,533 (1918). Hamon. Fuel (121,102.) Dec. 11.

III.—TAR AND TAR PRODUCTS.

APPLICATION.

Barrett Co. Process of sulphonating hydrocarbons and hydrocarbon derivatives. 19,686. Nov. 28. (U.S., 5,1,18.)

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Hart. Production of water-soluble dyes. 20,799. Dec. 13.

Inray (Soc. Chem. Ind. in Basle). Manufacture of mordant-dyeing dyestuffs etc. 20,534. Dec. 10.

Inrie (Geigy Soc. Anon.). Production of isatin and its substitution derivatives. 20,256. Dec. 6.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Charlesworth. Machines for drying or carbonising wool, cotton, etc. 20,560. Dec. 11.

Distillates, Ltd., and Jarmain. Treatment of effluent from piece etc. scouring processes. 20,859. Dec. 11.

Soc. Gén. pour la Fabr. des Mat. Plastiques. Preparation of nitrocellulose. 20,283. Dec. 6. (Fr., 6,12,17.)

Testrup, and Wetcarbonizing, Ltd. Hydrolysing cellulosic materials. 19,389. Nov. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

17,008 (1917). Frydensberg. Obtaining paper pulp and fibrous material from sea-tang. (120,761.) Dec. 4.

18,181 (1917). Knapp and Bartelds. Utilising old paper for producing new paper. (111,860.) Dec. 18.

7783 (1918). Unkle and Griley. Tub-beaters for paper pulp. (116,695.) Dec. 4.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Devy. Mercerisation. 20,696. Dec. 12.

Lord. Apparatus for treating hanks of yarn with liquids. 20,116. Dec. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

6017 (1918). Larivel. Machinery for dyeing and like treatment of textiles. (120,848.) Dec. 4.

7109 (1918). Lord and Lord. Machines for dyeing, washing, sizing, scouring, bleaching, and mercerising yarn in hank form. (121,075.) Dec. 11.

11,665 (1918). Clavel. Dyeing, bleaching, or like treatment of cops. (117,630.) Dec. 11.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

American Zinc Lead and Smelting Co. 20,208. *See* XIII.

Ashcroft. 20,714. *See* X.

Audienne. Heat-interchangers for gases applicable to the contact process for making sulphuric acid. 20,339. Dec. 7.

Bainbridge, Berry, Ollander, and Smith. Recovery of potash salts from furnace slag. 20,009. Dec. 3.

Cain, Couch, and Powell. Manufacture of potassium permanganate. 20,291. Dec. 6.

Hood. Purification of sulphur. 19,585. Nov. 27.

Norske Aktieselskab for Elektrokemisk Industri. Production of alumina from clay etc. 19,427. Nov. 26. (Norway, 24,1,18.)

Norske Aktieselskab for Elektrokemisk Industri. Removal of iron from solutions containing aluminium. 19,467. Nov. 26. (Norway, 23,2,18.)

Ramen. 19,826. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

13,617 (1917). Clarke and Clarke. Separation of thorium from other rare earths and manufacture of thorium nitrate. (120,748.) Dec. 4.

16,355 (1917). Brooke. Concentration or evaporation of waste acid liquors. (120,951.) Dec. 11.

16,879 (1917). Baker. Recovery and utilisation of the cyanides in gas-works by-products. (120,759.) Dec. 4.

3767 (1918). Dutt and Dutt. Manufacture of alumina. (120,838.) Dec. 4.

6062 (1918). Darasse. Catalytic apparatus for producing oxychloride of carbon and other substances. (115,422.) Dec. 18.

9130 (1918). Linder. Manufacture of sulphate of ammonia. (121,082.) Dec. 11.

13,436 (1918). Lytle. Manufacture of lead arsenate. (121,101.) Dec. 11.

14,359 (1918). Dawson. Manufacture of nitric acid. (120,869.) Dec. 4.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- Bawtree. Staining glass for signalling. 19,171. Nov. 26.
 British Thomson-Houston Co. (General Electric Co.). Composition for manufacture of glass. 19,592. Nov. 27.
 Curd. Hydrogen-heated glass reservoir furnace. 20,306. Dec. 7.
 Foster and Sankey. Manufacture of silica bricks, tiles, etc. 19,370. Nov. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,513 (1917). Howard. Feeding molten glass from furnaces etc. (120,744.) Dec. 4.
 17,474 (1917). Spinasse. Drawing glass. (114,819.) Dec. 11.
 18,116 (1917). Feldenheimer. Treatment of clay. (121,191.) Dec. 18.
 18,463 (1917). Maddock and Maddock. Kilns or ovens for use in making pottery, tiles, etc. (121,198.) Dec. 18.

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Boehm, Ltd., and Reihl. 20,513. *See* XIII.
 Mehta. Manufacture of preservative for wood etc. 19,388. Dec. 3.

X.—METALS; METALLURGY; INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Aclon. Process of using heat decomposition of nickel carbonyl to form protective coating of nickel on surfaces of oxidisable metal or alloy. 20,723. Dec. 12.
 Amalgamated Zinc (De Bavays), Ltd., and Gaudin. Recovery of lead and silver from sulphide ores and metallurgical products. 20,761. Dec. 12.
 Ashcroft. Cyclic process for simultaneous production of magnesium metal or alloys and alkali chlorates. 20,714. Dec. 12.
 Bainbridge and others. 20,009. *See* VII.
 Charpy. Eliminating faults due to piping and segregation in ingots of steel etc. 20,377. Dec. 7. (Fr., 297,18.)
 Dunningham, Hargreaves, and Hutchins. Manufacture of sodium. 20,634. Dec. 11.
 Edser, Tucker, and Minerals Separation, Ltd. Concentration of ores. 20,541. Dec. 10.
 Grover and Wigan. Aluminium alloys. 20,292. Dec. 6.
 Harris, and National Metal and Chemical Bank, Ltd. Roasting sulphide ores. 19,993. Dec. 3.
 Haywood. Copper-aluminium alloy. 20,550. Dec. 10.
 Imbery. Hardening and tempering metals and apparatus therefor. 20,120, 20,375, 20,385. Dec. 5 and 7.
 Leslie. Apparatus for testing hardness of metals etc. 19,866. Dec. 2.
 McNab. Metal. 20,692. Dec. 12.
 Metals Disintegrating Co. Process and apparatus for disintegrating metals. 20,080, 20,081. Dec. 4. (U.S., 20,12,17.)
 Moore. Electric metallurgical furnaces. 20,378. Dec. 7.
 Munden and Shilton. Crucible furnaces. 19,810. Nov. 30.
 Queneau. Treatment of tin sulphide ores to separate metallic tin. 19,469. Nov. 26.
 Ramen. Manufacture of burnt ore etc. bricks. 19,606. Nov. 27.
 Ramen. Obtaining metals from end-lyes containing metal chlorides. 19,826. Nov. 30.
 Rossi. Production of an acid-proof alloy. 20,810. Dec. 13.

- Westinghouse Lamp Co. 19,460 and 19,595. *See* 11.

COMPLETE SPECIFICATIONS ACCEPTED.

- 15,505 (1917). Jones. *See* XI.
 16,197 (1917). Jensen. Preserving metallic surfaces. (121,150.) Dec. 18.
 17,452 (1917). Roberis. Plating sheet metal. (112,125.) Dec. 11.
 17,973 (1917). Minerals Separation, Ltd. Apparatus for concentrating ores. (112,019.) Dec. 18.
 862 (1918). Taylor and Sons, Gaunt, White, and Brookfield. Smelting-furnaces. (121,213.) Dec. 18.
 2036 (1918). Berglund. Extraction of lead. (114,303.) Dec. 4.
 7019 (1918). Perry, and Industrial Inventions, Ltd. Production of malleable iron castings. (121,071.) Dec. 11.
 8829 (1918). Mackie. Gold concentrators. (121,253.) Dec. 18.
 10,626 (1918). Bennett. Furnaces for the heat treatment of steel. (118,598.) Dec. 18.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Elieson. Accumulator plates. 19,388. Nov. 25.
 E.L.A.T. Soc. Anon. Electric furnaces. 20,746. Dec. 12. (Ital., 12,12,17.)
 Harrison. Electric furnaces. 20,858. Dec. 14.
 Imbery. Electric muffle furnaces. 20,375. Dec. 7.
 Moore. 20,378. *See* X.
 Soc. Electro-Metallurgique Française. Electrodes for electric furnaces. 19,756. Nov. 29. (Fr., 312,17.)
 Tumelty. Insulating materials. 20,489. Dec. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

- 15,505 (1917). Jones. Electric muffle furnaces. (120,941.) Dec. 11.
 17,612 (1917). Grammont. Electric furnaces. (120,786.) Dec. 4.
 18,102 (1917). Chloride Electrical Storage Co., and Heap. Wood separators for secondary electric batteries. (121,188.) Dec. 18.
 18,319 (1917). Burns. Electrical separation of suspended particles from gaseous bodies. (120,994.) Dec. 11.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Blichfeldt. 20,079. *See* XIX.
 Firth. Treatment of soya beans for recovery of oil and production of synthetic milk and flour. 19,672. Nov. 28.
 Holdcroft and MacIlwaine. Extraction of oil by volatile solvents. 20,125. Dec. 9.
 King. Treatment of oils and fats. 20,175. Dec. 5.
 Martin. Hydrogenating oils. 19,567. Nov. 27.
 Park. Washing and drying copra. 19,609. Nov. 27.
 Warburton. Refining oils. 20,733. Dec. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 13,125 (1917). Sizer. Apparatus for expressing oils etc. from seeds, nuts, etc., and for compressing the residuum into solid form. (120,747.) Dec. 4.
 17,886 (1917). Escejay Co. Soaps and cleaning agents for use in laundries. (113,086.) Dec. 18.
 17,996 (1917). Barton. Oil-cake and like hydraulic presses. (120,990.) Dec. 18.
 19,305 (1917). Superior Oil and Process Co., and Schuck. Process of purifying oily materials. (120,820.) Dec. 4.
 2445 (1918). Hayashi and Kaisha. *See* XVII.
 3609 (1918). Norton. *See* XIX.
 4523 (1918). Lockwood and Samuel. Treatment of fatty acids or their metallic salts, and manufacture of oxidised products therefrom. (121,237.) Dec. 18.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

American Zinc Lead and Smelting Co. Preparing pigment zinc oxide. 20,208. Dec. 5. (U.S., 9,118.)

Boehm, Ltd., and Reihl. Manufacture of paint oils for cement, concrete, etc. 20,513. Dec. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

18,342 (1917). Peachey. Plastic or solid material applicable also as varnish, lacquer, coating, or dope. (121,194.) Dec. 18.

4523 (1918). Lockwood and Samuel. *See XII.*

11,267 (1918). Peachey. Manufacture of a plastic or solid material applicable also as a varnish coating, dope, or lacquer. (121,091.) Dec. 11.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATION ACCEPTED.

147 (1918). Jackson (India Rubber Co.). Production of pigmented rubbers. (120,824.) Dec. 4.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Bonamico. Tanning hides. 20,077. Dec. 4. (Italy, 4,12,17.)

Channon. Liquid glue. 19,897. Dec. 2.

Dorr Co. Recovery of proteids from waste liquors of hide-treating art. 20,284. Dec. 6. (U.S., 2,3,18.)

Drury. Leather compositions. 19,902. Dec. 2.

Forster. Treating hides and skins in manufacture of leather. 20,401. Dec. 9.

Stocks. Composition in lieu of leather etc. 19,763. Nov. 29. (Australia, 27,10,17.)

COMPLETE SPECIFICATION ACCEPTED.

18,176 (1917). White. Making composition from leather scrap. (120,802.) Dec. 4.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Allison and Goulding. Apparatus for manufacture of superphosphates etc. 20,597. Dec. 11.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Goold (American Laundry Machinery Co.). Method and apparatus for preparing starch. 19,520, 19,529, 19,539. Nov. 27.

Martin. Manufacture of lactose or milk sugar. 19,692 and 20,836. Nov. 28 and Dec. 13.

Stephenson. Treatment or handling of sugar cane. 29,609. Dec. 11.

COMPLETE SPECIFICATION ACCEPTED.

2445 (1918). Hayashi and Kaisha. Manufacture of decolorising carbon. (121,035.) Dec. 11.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Wooldridge. Brewing. 19,764 and 20,429. Nov. 29 and Dec. 9.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Berry, Mowbray, and Roberts and Co. Manufacture of baking powders and self-raising flours. 19,815. Nov. 30.

Blichfeldt. Apparatus for manufacture of margarine, etc. 20,079. Dec. 4.

Box. Destruction of house and other refuse and recovering useful materials. 20,427. Dec. 9.

Candy. Purification of water. 20,671. Dec. 12.

Cronsvive and Warnecke. Manufacture of feeding stuffs from marine plants. 20,197. Dec. 5. (Sweden, 20,8,15.)

Distillates, Ltd., and Jarman. 20,559. *See V.*
Erslev. Manufacture of artificial milk. 19,673. Nov. 28. (Holland, 5,1,17.)

Erslev. Improving tobacco. 19,674. Nov. 28. (Holland, 15,12,17.)

Firth. 19,672. *See XII.*

Fruited Cereal Co. Prepared health food. 19,984. Dec. 3. (U.S., 4,12,17.)

Fuessly, Hepworth, and Wilton. Softening, treating, and filtering water. 20,216. Dec. 6.

Gee. Animal foodstuffs. 20,363. Dec. 7.

Hobley and Martin. Treatment of salvage flour, meal, spoilt cereals, etc. 20,013—20,015. Dec. 5.

Lamb and Pennington. 19,386. *See II.*

Liversedge. Treatment of sewage etc. 20,652. Dec. 11.

MacDonald. 20,355. *See I.*

Oxley. Alimentary product. 20,664. Dec. 12.

Tarrant. Obtaining substances of value from sewage. 19,974. Dec. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

9291 (1917). Satow. Recovering proteids from vegetable proteid-containing material. (121,141.) Dec. 18.

17,442 (1917). Spencer. Preserving and sterilising milk, etc. (120,963.) Dec. 11.

17,458 (1917). Legg. Process of curing meats. (120,964.) Dec. 11.

18,044 (1917). Wilson. Apparatus for purifying water and other liquids. (121,180.) Dec. 18.

2123 (1918). Revis, Bolton, Downes, and Bellwood. Tanks or containers for ripening or souring milk or cream for use in making butter, margarine, etc. (121,033.) Dec. 11.

3609 (1918). Norton. Manufacture of margarine. (120,836.) Dec. 4.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Barbet et Fils et Cie., and Soc. Anon. de Prod. Chim. Etabl. Maletta. Manufacture of acetic ethers. 20,642. Dec. 11. (Fr., 20,10,17.)

Barrett Co. 19,686. *See III.*

Langley. Specific or medical compound. 20,702. Dec. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

10,181 (1917). Marks (Nagai). Synthetic drugs. (120,936.) Dec. 11.

4523 (1918). Lockwood and Samuel. *See XII.*

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Brown and Wellesley. Production of colour photography in natural colours on the film. 19,868. Dec. 2.

Rawlins. Photographie plates or negatives. 20,580. Dec. 11.

COMPLETE SPECIFICATION ACCEPTED.

4817 (1918). Scott. Coating films of celluloid etc. with sensitised photographic emulsion. (121,054.) Dec. 11.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Marin. Explosives. 20,180. Dec. 5. (Belg., 12, 11, 17.)

Soc. Gén. pour la Fabr. des Mat. Plastiques. 20,283. *See V.*

XXIII.—ANALYSIS.

APPLICATIONS.

Heathcote, and Rudge-Whitworth, Ltd. Means for ascertaining composition, nature, and effect of gases and vapours. 19,796. Nov. 30.

Leslie. 19,866. *See X.*
